CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

NEW EDITION

Edited by

DAVID PATRICK, M.A., LL.D.

AND

WILLIAM GEDDIE, M.A., B.Sc.

VOLUME IV

DIOPTRICS TO FREISTADTL

W. & R. CHAMBERS, LIMITED
LONDON and EDINBURGH

J. B. LIPPINCOTT COMPANY, PHILADELPHIA

1926

All Rights Reserved

Printed in Great Britain.
W. & R. CHAMBERS, LTD , LONDON and EDINBURGH.

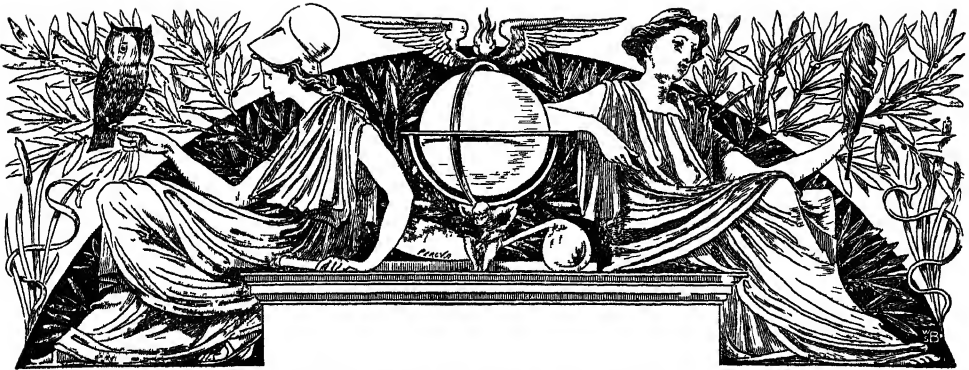

LIST OF MAPS AND PLATES IN VOLUME IV.

	PAGE
MAP, EGYPT	240
" ENGLAND AND WALES.	352
" EUROPE, POLITICAL	480
" " PHYSICAL	480
" " HISTORICAL, as at 9th, 12th, and 17th Centuries, and during Napoleon's Empire .	480
" " " as at 1908.	488
" FINLAND AND ESTONIA	656
" FRANCE—PROVINCES	800
" " DEPARTMENTS	800
FLAGS	688

Among the more important articles in this Volume are the following:

DIPHTHERIA.....	Professor JAMES RITCHIE.	ENGRAVING.....	J. M. GRAY; JAMES PATON
DIPLOMACY; ENEMY...	Sheriff J. M. IRVINE, K.C., LL.D.	EPIDEMIC... ..	Dr JOHN M. COMRIE.
DIPPER.	Professor J. ARTHUR THOMSON.	ERASMUS. . . .	Professor P. HUME BROWN, LL.D.
DIPPING-NEEDLE.....	Professor A. C. MITCHELL.	ESPERANTO.	G. DAWSON LEWIS
DIPSOMANIA.....	Professor Sir JOHN MACPHERSON.	ETHICS.....	Professor W. R. SORLEY.
DISEASE.. . . .	Dr JOHN M. COMRIE.	ETHNOLOGY.....	Professor A. H. KEANE.
DISTILLATION; ETHER	W. INGLIS CLARK, D.Sc.	EUCLID.	J. S. MACKAY, LL.D.
DIVINATION	THOMAS DAVIDSON.	EUGENICS.....	ETHEL M. ELDERTON.
DIVISION OF LABOUR. .	THOMAS KIRKUP.	EURIPIDES.. . .	Professor F. B. JEVONS, Litt.D.
DIVORCE; ENTAIL.	Sir THOMAS RALEIGH, K.C.S.I.	EURYPTERIDA... ..	Dr ROBERT CAMPBELL.
DOCK; DREDGER.....	D. & C. STEVENSON.	EVOLUTION. . . .	Professor PATRICK GEDDES.
DOG; FOX.....	W. E. HOYLE, D.Sc., F.Z.S.	EXCOMMUNICATION ..	Rev. Dr R. F. LITTLEDALE
DOGMA; ECCLESIASTES	Rev. Professor H. T. ANDREWS, D.D.	FACTORY ACTS	Sheriff J. M. IRVINE, K.C., LL.D.
DORIANS.....	Professor F. B. JEVONS, Litt.D.	FALCONRY.	J. E. HARTING, F.Z.S.
DOUGLAS.....	JOSEPH ROBERTSON, LL.D.	FALLOW; FENCES. . .	Professor WALLACE.
DRAINAGE; FARM.....	J. MACDONALD; Professor J. A. S. WATSON.	FAMILY.. . . .	NORTHCOOTE W. THOMAS.
DRAMA; DRYDEN.....	Professor SAINTSBURY.	FARADAY.	Professor P. G. TAIT.
DRAYTON; FORD.....	A. H. BULLEN.	FASHION.....	EMILY STEVENSON.
DREAMS; EPILEPSY....	Dr A. NINIAN BRUCE.	FAST; FESTIVAL.....	EMANUEL DEUTSCH.
DRUIDISM.	Right Hon. Sir JOHN RHYS.	FATS... ..	Professor NOEL PATON.
DUMAS.....	W. E. HENLEY.	FÉNELON.....	Very Rev. CHARLES W. RUSSELL, D.D.
DUNDEE...	J. A. S. BARRETT.	FERMENTATION.....	Professor A. HARDEN.
DURER.....	J. M. GRAY.	FERNS; FLOWER... ..	Professor PATRICK GEDDES; GEORGE WEST.
DYEING.....	A. B. STEVEN.	FIARS.....	Sheriff J. M. IRVINE, K.C., LL.D.
DYNAMITE, &c.....	Colonel Sir HILARY BARLOW, Bart.	FIBRIN.....	Dr G. M. WISHART.
DYNAMOS; ELECTRIC		FICHTE.....	W. SMITH, LL.D.
LIGHT and RAILWAY.	Principal Sir A. EWING, F.R.S.	FIELDING.....	AUSTIN DOBSON.
DYSENTERY; EYE.....	Dr R. A. LUNDIE.	FIRDAUSI.....	W. A. CLOUSTON.
E; F.....	Dr HENRY BRADLEY.	FIREARMS.....	W. GREENER.
EAR.. . . .	Dr M'BRIDE; Dr W. G. PORTER.	FIRE-BRIGADE.....	ARTHUR FORDAGE.
EARLY ENGLISH.....	D. MACGIBBON.	FISHES... ..	Professor J. ARTHUR THOMSON.
EARTH.....	Dr. HUGH ROBERT MILL.	FITZGERALD, EDWARD.	Professor E. B. COWELL.
EARTHQUAKE. . . .	Professor JAMES GEIKIE.	FLAG.	Sir JAMES BALFOUR PAUL, Lyon King
EARTHWORM; EARWIG.	Professor J. ARTHUR THOMSON.	FLAME.. . . .	Professor W. A. BONE.
EASTER; FAIRIES.....	Rev. T. F. THISELTON DYER.	FLAUBERT	Professor SAINTSBURY.
ÉCARTÉ; EUCHRE.....	HENRY JONES ('Cavendish').	FLIGHT OF ANIMALS..	F. W. HEADLEY.
ECKHART.	J. T. BEALBY.	FLY-WHEEL.	Professor T. II. BEARE.
ECLIPSES.....	Sir FRANK W. DYSON, F.R.S., Astro- nomer-Royal.	FETUS.....	Dr MILNE MURRAY.
ECOLOGY.....	Dr W. G. SMITH.	FOOD.....	Professor HAYCRAIT.
EDGEWORTH.....	F. HINDES GROOME.	FOOT.	Professor HEBURN.
EDUCATION.. . . .	Professor JOHN ADAMS, LL.D.	FOOTBALL....	C. J. BUTCHER, of the Field.
EDWARD I.-V.	THOMAS DAVIDSON.	FORCE.....	Professor P. C. TAIT.
EGYPT.. . . .	S. BIRCH, LL.D., Miss M. A. MURRAY, and Professor S. LANE-POOLE.	FORGERY.....	Sir A. WOOD RENTON.
ELECTRICITY.....	Professor CARGILL G. KNOTT.	FORTIFICATION.. . .	Colonel DUNLOP, R.A.
ELECTRON... ..	Sir OLIVER LODGE.	FOX, GEORGE.....	Rev. W. W. TULLOCH.
ELIOT, GEORGE.....	RICHARD HOLT HUTTON.	FOX, JOHN.....	Sir SIDNEY LEE.
ELIZABETH.....	WILLIAM WALLACE, LL.D.	FOX-HUNTING.....	CHARLES RICHARDSON.
EMBROIDERY; ENAMEL	JAMES PATON.	FOUNDLING HOSPITALS	Rev. H. F. B. COMPTON.
EMBRYOLOGY.....	Professor J. ARTHUR THOMSON.	FOURIER.....	THOMAS KIRKUP.
EMERSON.....	Dr OLIVER WENDELL HOLMES.	FRANCE (Geography)...	Prince PETER KROPOTKIN.
ENERGY; ETHER.....	Professor W. PEDDIE, D.Sc.	FRANCE (History, Lan- guage and Literature)	F. F. ROGET.
ENGLAND, CHURCH OF..	Rev. Dr R. F. LITTLEDALE.	FRANCIS, SIR PHILIP...	W. FRASER RAE.
ENGLISH LANGUAGE...	Professor H. CECIL WYLD.	FRANKLIN, BENJAMIN.	Hon. JOHN BIGLOW.
ENGLISH LITERATURE..	Professor HENRY MORLEY, LL.D.	FREDERICK THE GREAT	FINDLAY MUIRHEAD.
		FREE TRADE.....	Professor J. S. NICOLSON.

A great many of the articles named above are new; others written for earlier issues of this Encyclopædia have been so thoroughly revised by their authors as to be virtually new. In addition to these many other revisers have taken part, including Professor J. A. S. WATSON (Agriculture), Mr C. INGLIS CLARK, Dr DRINKWATER, Mr WILLIAM MORISON (Chemistry), Dr MARY T. RANKIN (Economics), Professor FREDERIC BACON (Engineering), Dr R. W. JOHNSTONE (Art. Fœtus), Mr J. LIDDELL GEDDIE (Art. France), Dr ROBERT CAMPBELL (Geology), Mr G. E. SHEPHERD (India), Sheriff IRVINE, Sheriff DUNBAR (Law), Dr JOHN D. COMRIE (Medicine), Mr R. C. MOSSMAN (Meteorology), Captain H. M. JOHNSTONE, R.E. (Military subjects), Admiral Sir REGINALD TUPPER (Naval subjects), Professor W. PEDDIE (Physics). Thanks are due for information supplied by Mr OSSIAN DONNER, Finnish Minister in London, and Mr PAPE COWL (Finland), Mr R. MOLLERSON, First Secretary of the Estonian Legation (Esthonia), and Dr A. H. MILLAR (Dundee).

CHAMBERS'S ENCYCLOPÆDIA

A DICTIONARY OF UNIVERSAL KNOWLEDGE

Dioptrics is that branch of geometrical optics which treats of the transmission of rays of light from one medium into another differing in kind. It consists of the results of the application of geometry to ascertain in particular cases the action of what are called the

laws of refraction. See OPTICS, REFRACTION, LIGHTHOUSE.

Diorama. See PANORAMA.

Diorite. See IGNEOUS ROCKS, PETROGRAPHY.

Dioscorëa'ceæ, an order of Monocotyledons, of which the genus *Dioscorea* (see YAM) is the type. There are about 170 species, temperate or tropical, all twining shrubs, with large rootstocks or tubers. *Testudinaria elephantipes*, a South African species, sometimes called Elephant's Foot and Hottentots' Bread (q.v.), has a large fleshy rhizome, with a rough cracked bark, which is used as food by the Hottentots in times of scarcity. *Tamus communis* (Black Bryony) is the only British representative of the order.

Dioscorides, PEDACIUS, or PEDANIUS, a Greek physician, was a native of Anazarba in Cilicia, and, probably in the 2d century of our era, accompanied the Roman armies as physician through many countries. He has left a great work on materia medica, in five books, in which he treats of all the then known medicinal substances and their properties, real or reputed. His authority in botany and materia medica was long undisputed, and is still maintained in the East. The best editions of Dioscorides, including some smaller works bearing his name, are by Salacenus (1598) and Sprengel (2 vols. 1829-30).

DioscURI. See CASTOR AND POLLUX.

Diosma. See BUCKU.

Diospyros. See DATE PLUM, and EBONY.

Dip, in Geology, is the inclination of strata downwards into the earth. The amount or angle of dip is the degree of deviation from a level line, or the plane of the horizon. See HORIZON.

Diphtheria (Gr. *diphthera*, 'a pellicle') was described in 1828 by M. Bretonneau of Tours as a form of very fatal sore throat, occurring chiefly in children. In its milder forms the disease resembles other inflammations in the throat, but a case can be recognised by the finding of the diphtheria bacillus in the inflamed area. The disease begins by malaise, feeling of chilliness, loss of appetite, headache, and more or less fever; soon the throat feels hot and painful, whilst the neck is stiff and tender. If seen early, the throat is red and swollen, but a false membrane of yellowish or grayish colour quickly appears in spreading patches on an inflamed and ulcerated base in the pharynx or back of the throat, and often extends down the oesophagus or gullet, one side usually being more affected than the other. There may be enlargement of the glands at the angle of the jaw, and albuminuria generally occurs at some stage of the disease. Diphtheritic membrane may be got on any mucous surface, or even on a wound; if it extends into the larynx, it gives rise to difficulty in breathing. The throat affection is often accompanied by a low and very dangerous form of fever, with great and rapid loss of the patient's strength, which is still further reduced by difficulty in taking food; in other cases, the disease is fatal by paralysis of the heart, or by suffocation, due to invasion of the larynx, when tracheotomy may require to be resorted to. After the acute disease is over, the recovery may be delayed by paralytic symptoms of various kinds; or simply by extreme debility, with exhaustion and loss of appetite. Diphtheria is contagious, the bacillus being conveyed from individual to individual by the air, and it has the peculiar tendency of tacking itself on to other diseases, especially scarlet fever. Damp and temperate climates seem to favour its development, while the contagium may remain dormant for long

periods. Outbreaks are stated to have been traced to impure drainage and bad water. One attack affords only slight protection against recurrence. Diphtheria is caused by the diphtheria bacillus, discovered by Loeffler in 1884. The organism, multiplying in the throat, gives rise to the local inflammation, and also produces a powerful poison which, being absorbed into the body, causes the heart weakness and the paralysis alluded to above. This latter fact was proved by Roux of Paris finding that when the bacilli are grown in beef broth and subsequently removed by filtration through an earthenware filter, the remaining fluid or toxin, on injection into animals, gives rise to typical post-diphtheritic paralysis. The discovery led to Behring in 1893 elaborating the idea of treating the disease by antitoxin. If such an animal as the horse receives every few days increasing doses of the toxin, its serum, after two or three months, is found to contain a substance—antitoxin—which, when injected into animals, protects them against infection either with the diphtheria bacillus or its toxin; furthermore, even after infection, injections of the antitoxin will in a great many cases prevent death. Behring found that the last fact was also true in natural infection occurring in man, the inflammation in the throat being checked, and the general toxic effects being minimised. The antitoxin treatment thus discovered has diminished the mortality of diphtheria from 45 per cent. to about 10 per cent. Its success depends on its early application, if possible on the first day of the disease. A method was devised by Schick in 1913 of discovering by inoculation persons susceptible to diphtheria. The administration of a small dose of antitoxin to these affords protection against the disease. Besides the administration of antitoxin, the treatment consists in keeping up the strength of the patient by means of concentrated beef-tea, milk, egg-flip, &c. Iron in large doses is most valuable, and sometimes quinine. Locally, solvents, such as lactic acid, are applied to the throat by a brush; antiseptics are also useful, the best being Condy's fluid. It has been found that after an attack of diphtheria the bacilli may remain in the throat for weeks or months. It is chiefly by means of such 'diphtheria carriers' that the disease is kept alive in a community and fresh outbreaks originated. A diphtheria convalescent should not be allowed to mix with healthy people till bacteriological investigation has shown that no living diphtheria bacilli remain in the throat.

Diphthong. See PHONETICS, SPELLING.

Diplodocus, a gigantic dinosaur of the sub-order Sauropoda, found in the Jurassic rocks of the western states of the American Union. One of the largest (if not the very largest) of animals known to have walked this globe, it had a comparatively short and low body, a small head, with slender teeth only in the front parts of the jaws, a very long neck, and was herbivorous and apparently aquatic. The total length was perhaps 75 or 80 feet, of which 20 fell to the neck and only 2 to the head; the weight must have been some 20 tons. In 1905 Mr Carnegie presented a cast of one from the mountains of Wyoming to the British Museum. The name was coined in 1878 by Dr O. C. Marsh (q.v.), to whom we owe the knowledge of so many of these dinosaurs, and is derived from Gr. *diploos*, 'double,' and *dokos*, 'beam' or 'bar.' See DINOSAURIA.

Diplo'ma (Gr., 'something doubled'), originally a document on two tablets of wax (see DIPTYCH), or on writing material which was folded. The Roman emperors granted diplomas to couriers, giving them the use of public servants and horses;

hence diploma came to signify an official warrant of any kind. The term is now mostly applied to documents given by universities and other learned societies, in proof of the holder having attained a certain degree; to the licenses held by physicians and surgeons; and to certificates of merit awarded at exhibitions.

Diplomacy (from *diploma* in the sense of 'public document'), the art of conducting the intercourse and adjusting the mutual relations of nations, arises out of the necessary interdependence of states, and the rights and duties of political intercourse. Although the art of diplomacy is as old as official intercourse between states, the special class of officials now known as diplomatists did not, and could not, exist until permanent legations were instituted. The general rules regulating the authority of accredited diplomatic representatives and the means by which the intercourse between states is conducted, are embodied partly in international usages and partly in treaties.

The classification of diplomatic agents resident in foreign countries was regulated by the protocols of the Congress of Vienna in 1815, and the Congress of Aix-la-Chapelle in 1818. It is as follows: (1) Ambassadors and papal legates or nuncios; (2) envoys extraordinary, or ministers plenipotentiary; (3) ministers resident accredited to the sovereign; (4) *chargés d'affaires* accredited, not to the sovereign, but to the minister for foreign affairs. This classification is only of importance in relation to questions of precedence and ceremonial. In the diplomatic hierarchy ambassadors, being considered personal representatives of the heads of their states, enjoy special honours. Thus in the United Kingdom they rank in precedence immediately after the princes of the blood-royal.

A diplomatic agent is furnished with a letter of credence, announcing his appointment and requesting that full faith and credit be given to what he shall say on behalf of his state. This letter is presented by him to the government to which he is sent. Where a diplomatic envoy is entrusted with the conduct of specific negotiations, which are outwith the ordinary business of a permanent legation, e.g. the negotiation of a commercial treaty, it is necessary to furnish him with special powers, which may either be contained in the letter of credence, or, as is more usual, may be conferred by letters patent.

The most complete personal independence and freedom of action are essential to the efficient performance of the duties of a diplomatic agent. The inviolability of international agents was recognised by the nations of antiquity, and has been accepted in modern times as inseparable from the right of legation. This privilege is enjoyed from the moment that a diplomatic envoy enters the territory of the state to which he is accredited until he leaves that territory. During his residence in that state he continues to be domiciled in, and to be entitled to the protection of the municipal laws of his home state. He is exempt from the jurisdiction, both civil and criminal, of the state in which he resides. Thus, in England a foreign ambassador cannot be sued against his will, even in respect of private commercial transactions; and this privilege extends to his family and suite, attachés and secretaries, and domestic servants. This immunity, which is absolute in the case of an ambassador himself, is forfeited in the case of a member of his establishment if such a person engages in trade. The official residence of an ambassador cannot be entered by officers of justice, police, or revenue of the state to which he is accredited, unless he specially permits such entry. His residence is, indeed, by a fiction of law, held

to be a part of the territory of the state which he represents. On this fiction of extritoriality was based the so-called right of asylum, under which criminals or other persons taking refuge within a foreign embassy secured freedom from arrest. The claim to grant such asylum has in practice been abandoned, and English law does not recognise any right of asylum as attaching to a foreign embassy. The right to freedom of religious worship (*droit de chapelle*) has long been recognised, and the larger tolerance of modern times in religious matters has deprived that right of much of its former significance.

Until the beginning of the 18th century Latin was the language generally used in diplomatic intercourse. French, however, gradually displaced Latin as the diplomatic language of states. At the Peace Conference at Paris in 1919, the English and French languages were employed on a footing of equality, and the English and French texts of the Treaty of Peace with Germany, and the Covenant of the League of Nations, are both authentic.

The permanent diplomatic agents of the several states not merely carry on the necessary intercourse and communications between their respective states, but are constantly engaged in adjusting points of difference, and in exchanging views on questions affecting the relations of these states. It is the duty of an ambassador, or other permanent diplomatic envoy, to keep his government informed on all matters of state policy or of political interest in the country in which he is resident; to protect the persons and property of subjects of his home state, and, in case of injury to them, to secure a remedy; and, in general, to forward the interests of his home state and those of its individual subjects. He must, however, scrupulously abstain from interference in the internal affairs of the state to which he is accredited. If he violates this rule, the state to which he is accredited may request that he be recalled. Thus, in September 1915, Dr Dumba, the Austro-Hungarian ambassador in Washington, was, at the request of the United States, recalled for proposing plans to instigate strikes in American munition factories, and for employing an American citizen, with an American passport, to carry official despatches secretly to Austria through the lines of the enemies of Austria.

In recent years many changes have been made in the organisation of the British diplomatic service. The foreign office and the diplomatic service, always closely associated, are now amalgamated. The examination for entrance to the service is the same as that for the general civil service and the Indian civil service, special provision being made to ensure that the candidates attain a high standard in French and German. Between the diplomatic service and the consular service, a new commercial diplomatic service has been formed. In the more important countries there is now a commercial counsellor, who is the deputy of the ambassador, and who has under him one or more commercial secretaries. In less important countries there is a commercial first secretary with a suitable staff.

Colloquially the term is frequently applied to conduct which, if not altogether fraudulent, is characterised by a certain degree of cunning and subtlety. This use of the word probably arose from the popular impression that, in conducting the affairs of nations, there is in use a code of morality which would be condemned if practised by individuals in their intercourse with each other. Nor, judging from the old literature of legation, can it be said that this popular conception of the ambassador and his functions was altogether unfounded. Of late years,

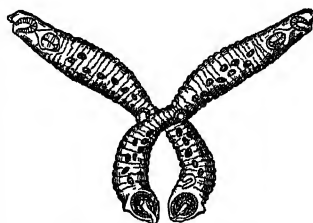

however, the general progress of international morality, and more advanced conceptions of international relations, have considerably modified the older view of the functions of diplomacy and diplomatists. Speech in the mouth of a diplomatist is no longer an instrument for the concealment of thought; an ambassador is no more a functionary commissioned 'to lie abroad for the advantage of his country,' but one selected to tell the truth on her behalf.

The phrase *Corps Diplomatique* is usual for the whole body of ministers who are present at any court as representatives of foreign countries.

See P. Satow, *A Guide to Diplomatic Practice* (2 vols. London, 1917); Callières, *The Practice of Diplomacy* (London, 1919); D. P. Heatley, *Diplomacy* (Oxford, 1919); and Treatises on International Law.

Diplomatics, the science of dealing with historical documents, is closely connected with *Palaeography* (q.v.). See RECORDS.

Diplozoon (Gr., 'double animal'), a remarkable flat worm or Trematode. It consists of two organisms fused together. The embryo, known as *Diporpa*, is ciliated and free-swimming, but soon relapses into parasitism. It loses its cilia, settles on a minnow's gills, loses its eyes, and remains for weeks or months like many another Fluke (q.v.). Finally, however, a curious phenomenon occurs. One individual moors itself by its ventral sucker to a conical knob on the back of another, 'which thereupon so twists itself as to fix the first individual in the same manner.' The cones and suckers are closely fused, but otherwise the secondarily twin animals remain independent. This double Trematode well deserves its name of *Diplozoon paradoxum*. See Zeller, *Zeitschr. f. wiss. Zool.* xxix. (1877).

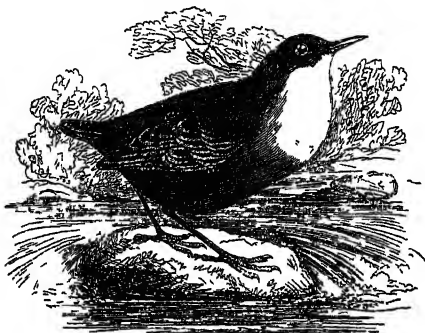

Diplozoon paradoxum.
(From Leunius, after Zeller.)

Dipnoi (lit. 'double-breathers'), a small order of fishes in which the air-bladder has become a single or double lung. See CERATODUS, LEPIDOSIREN, and MUD FISHES.

Dippel's Animal Oil, a panacea invented by Johann Konrad Dippel (1673-1734), a German chemist and alchemist. It was obtained in the manufacture of ammoniacal products by the distillation of bones. A mixture of oils passes over, and these, after being repeatedly distilled, eventually yield an aromatic liquid, free from fetid odour. This obtained a great reputation as an antispasmodic, and being present in the old spirit of hartshorn, gave it properties somewhat different from those of the modern sal volatile. Owing to the careless way in which it was usually manufactured, and the consequent disgusting odour and taste which it possessed, it has been quite discarded and is no longer used in medicine.

Dipper (*Cinclus*), a genus in the family Cinclidae, sometimes mistakenly referred to thrushes. The bill is straight, and there is a membrane partially covering the nostrils; the wings are short and rounded; the tail is very short; there is a complete layer of dense down beneath the close-set outer feathers. Dippers frequent clear pebbly streams and lakes, feeding chiefly on molluscs and on aquatic insects and their larvæ. The bird carries its short tail elevated after the manner

of wrens, which it also resembles in the frequent dipping of the head, accompanied with an upward jerking of the tail. One species is found in Britain, the Common Dipper or Water Ousel (*C. aquaticus*), a bird about seven inches in length, silky black above, with throat and upper part of the breast pure white, and then a band of chestnut-brown. It is found throughout central and western Europe, and the genus has a world-wide representation. It is not gregarious. The dipper never fails to attract notice, as it sits upon some stone in the midst of or beside the stream, its white breast

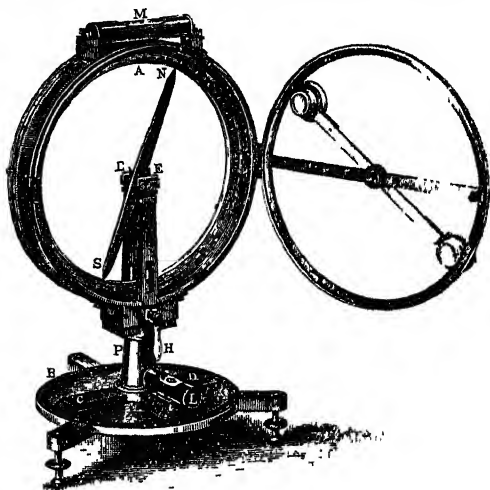

Water Ousel (*Cinclus aquaticus*).

rendering it conspicuous as it repeats the movement from which it derives its name. Its song is not confined to the breeding season, and may even be heard among the frosts of winter. Its movements under water are imperfectly understood; it walks quickly along the bottom, and also uses its wings like oars. The nest of interwoven moss, domed and with the entrance on the side, is built usually in some mossy bank close by a stream, and often near or under a cascade. The dipper breeds twice in the year. There are 4 to 6 dull white eggs. The statement is often made that it eats the spawn of fishes, but this charge is baseless. On the contrary, the dipper often devours the enemies of spawn.

Dipping-needle, or DIP CIRCLE. The magnetic dip or inclination, one of the three elements necessary for the complete determination of the earth's total magnetic force at any place, is defined to be the angle which the magnetic axis of a magnet, swinging freely in the plane of the magnetic meridian, makes with the horizon. The dipping-needle which is employed to determine its amount at any place, consists essentially, therefore, of a magnetic needle suspended in the plane of the magnetic meridian, so that it can indicate, on a graduated circle in its plane, the angle required. In the accompanying figure one form of the instrument is represented. A is a vertical brass circle, graduated into degrees and fractions of a degree, inclosed between circular glass doors (one of which is seen opened in the figure), and supported on the pillar P. This pillar fits into a socket in the horizontal circular disc B, also graduated at its margin, and from the base of the pillar two flat brass strips, CD, reach on opposite sides to the graduated edge. The horizontal disc is supported on three legs, whose lengths can be adjusted by screwing or unscrewing. On this horizontal circle the vertical circle can be turned in azimuth. The needle, NS, a thin flat piece of steel, pointed at both ends, is suspended in the plane of the vertical circle by means of hard, polished, cylindrical axles passing through its centre of gravity, and rolling on the agate edges, EE. When the indications of the needle are not actually being read, the axles may

be raised by, so as to rest on, two Y-shaped brass edges, which are lifted or depressed again by turning the handle H. On the outside of the glass door a light cross-bar carries a flat rod, at each end of which a magnifying lens or microscope is placed to read off the dip of the needle as indicated by its ends, on the graduated vertical circle. For the purpose of setting the one circle truly horizontal and the other truly vertical, one level, L, is placed on the horizontal circle, and another, M, on the top of the vertical circle.

If the needle be swinging freely in the plane of the magnetic meridian, if its centre of gravity lies in the axis on which it is free to rotate, and if its magnetic axis coincides with its axis of figure, it

Dipping-needle.

will correctly indicate the dip. But there are numerous errors possible in such an instrument which can only be avoided by taking the mean of two observations which have errors of equal amount but of opposite sign. This duplication of observations has to be carried out for each of the known possible instrumental errors, so that finally the true angle of inclination or dip is obtained, as the mean of no less than sixteen readings. The errors in question may be due to the following causes: (1) The vertical circle may not be properly set, and in consequence, when the needle is standing vertically, it does not point exactly to 90°, as it should; (2) the bearings of the needle may not be exactly in the centre of the circle; (3) the centre of gravity of the needle may not be in the axis on which it can rotate; (4) its magnetic axis may not coincide with its axis of figure; (5) there may be friction or adhesion at the bearings.

In making an observation of the inclination with the instrument, the first requisite is the adjustment to verticality of the vertical circle by means of the levels. The plane of the magnetic meridian must then be found, and the axis turned round until the vertical circle is in that plane. This is done by finding the position in which the needle stands vertically, for in that position, which is at right angles to the plane of the magnetic meridian, the horizontal component of the earth's magnetic force is non-effective, owing to the mode of suspension; the vertical component only is effective, and causes the needle to hang vertically. The plane of the needle is then moved through 90°, and is thus brought into the magnetic meridian. In making this observation of the plane in which the needle stands vertically, it is necessary, in order to elimin-

ate the effect of faults in construction already noted, to take a reading from the lower end, and one from the upper end of the needle; then, turning the circle round through 180° , to make other two in the same way; the mean of these four readings, with 90° subtracted, gives the plane of the meridian. To determine the angle of dip, four readings are taken, two with the face of the instrument towards magnetic east, and two with it facing magnetic west; one of each two being with a marked side of the needle facing the circle, the other being in the reversed position. The needle is then magnetised afresh, so that its polarity is reversed, and another series of four similar readings is obtained. The mean of these eight readings gives the true amount of the inclination.

The tuning of the instrument through 180° is to avoid any error due to that noted above as (1); to counteract (2), readings of both ends of the needle are taken; presenting both faces (or sides) of the needle, neutralises the effect of any error such as (3); errors such as (4) are obviated by the reversal of polarity.

The dipping-needle is not of such form as is convenient for continuous registration; for these requirements—i.e. the variations of the vertical component of the earth's magnetic force, the vertical force magnetometer is used. See MAGNETOMETER.

Diprotodon, a huge Australian Tertiary marsupial, a gigantic kangaroo. The head alone was 3 feet long. See KANGAROO.

Dipsacæ, or DIPSACACEÆ, the order of Teasel (q.v.) and Scabious (q.v.).

Dipsas, a genus of non-venomous serpents of the family Colubridæ. The body is much compressed laterally; the head is thick, blunt, and distinct from the neck; the scales are smooth. They are nocturnal, arboreal animals, feeding chiefly on lizards, frogs, and small birds, and are most abundant in neotropical and oriental regions. *D. dendrophila*, from the East Indies, is over six feet in length. *Dipsas cyanodon* is a large and beautiful species found in Java and Sumatra.

Dipsas cyanodon.

Dip-sector, an astronomical instrument for determining the dip of the horizon, is in principle similar to the Sextant (q.v.). See HORIZON.

Dipsomania is the typical form in which the morbid craving for alcohol and other nerve stimulants manifests itself. The craving attacks are recurrent, often periodic, and in the intervals between them the subjects may either abstain altogether—which they are often able to do without difficulty—or they may take alcohol regularly without exceeding the bounds of moderation. The

instinctive character of dipsomania is manifested in its symptoms, the chief of which are suggestibility, impulse, and suppression. After recovery from the drinking bout the painful experience is effectively suppressed from consciousness to such an extent that the inclination to alcohol may be converted into a repugnance towards it, and the subject believes that a recurrence of the experience is impossible. This psychological process of forgetting is quite natural, although,

to the uninitiated, it forms one of the most puzzling symptoms of the malady. But although the experience is thus suppressed, it remains independently active in the unconscious, and is liable to be reawakened into conscious activity under the influence of suggestions of various kinds, of which alcohol itself is the most potent. When a powerful, suppressed experience gains an ascendancy over the controlling mental processes responsible for its suppression, it usually displays the instinctive character of an impelling impulse. The subject, aware of the danger and alive to the painfulness of his past experience, endeavours to repress the complex, but too often is overcome by a force stronger than his own impaired will. There is every degree of difference between the ordinary forms of Alcoholism (q.v.) and what have been called the pathological forms, to which the term dipsomania has hitherto been generally applied, but the main characteristics—suggestibility, recurrence, and impulse—are essentially the same. It is true that many of the subjects of the exaggerated forms of alcoholism have an hereditary tendency to the neuroses and to insanity, and that they often manifest a stronger craving for, and a stronger impulse towards, nerve stimulants than less neurotic individuals. So powerful may this impulse be, and so inaccessible to advice or control, that some authorities look upon the pathological form as true dipsomania, which they compare with epilepsy or certain phases of mania. As has been pointed out, however, the difference between the ordinary and the pathological forms is only one of degree, and dipsomania, notwithstanding its name, must be regarded as merely a more pronounced manifestation of the abnormal impulse to indulge in narcotic stimulants.

Diptera, an order of two-winged insects, distinguished even by Aristotle. The wings are transparent, never folded, with predominant longitudinal veins; the hind-wings are transformed into small 'balancers' or 'halteres,' rarely absent; the mouth organs are adapted for piercing and sucking, the palps on the first pair of maxillæ are free or absent, those of the second pair are modified into a tongue or labella; there is a complete metamorphosis (larva, pupa, and imago); the larva is a footless maggot or a grub with secondary feet, its mouth parts are adapted for biting or for sucking; those of the pupa are adapted for sucking. The order is very large, numbering probably from 15,000 to 18,000 species, not including the fossil forms preserved in amber and the like. Many species, both as adults and as larvae, are directly or indirectly of economic importance because of their attacks on man, domestic animals, household stores, and cultivated plants; others again mitigate the ravages of other insects. The order will be sufficiently illustrated under separate articles—e.g. BLOW-FLY, CORN INSECTS, DADDY-LONG-LEGS, GNAT, HESIAN FLY, HOUSE-FLY, MIDGE, &c.

Dipterocarpaceæ, or DIPTERACEÆ, an East Indian order of archichlamydeous dicotyledons, including about 300 species, of which many are majestic trees, valued alike for timber and balsamic resins (see SAL, COPAL, DAMMAR, &c.). *Dipterocarpus turbinatus*, the Gurjun tree, and other species yield a fragrant oily resin, the so-called Gurjun balsam, while that of other species is sometimes called Dammar. Their timber is valuable for sleepers, &c. The seeds of various species of Shorea and other genera, especially *S. stenoptera*, growing in Borneo, Sumatra, and Java, yield Borneo tallow, a fat resembling cocoa butter in characters and uses. These are sometimes called illipe nuts, a name better confined to the fruits of Bassia and other Sapotaceæ. For the Malabar tallow-tree, see TALLOW-TREE.

Diptych, a two-leaved writing tablet, in which were inscribed the names of living or dead Christians to be read aloud during the celebration of the eucharist. The practice was due originally to a custom under the Roman empire of magistrates, such as consuls, prætors, and ædiles, at the commencement of their office, giving away tablets inscribed with their names and portraits. In Christian usage it was in very early times customary to inscribe the names of dead bishops—a beginning of the calendars and martyrologies of later days. The insertion of the names of living persons may have had its origin in the ancient recital of the names of those who had voluntarily furnished the elements for the holy communion. It afterwards was extended to include the names of the living faithful, especially those in authority, ecclesiastical and civil. The commemoration of the faithful dead was originally distinct from any special prayer on their behalf. The earliest diptychs in existence are not older than the 5th century of our era. They are of various sizes, rarely exceeding eight inches by four, are sometimes of ivory and metal, as well as wood, and are adorned with an art that is elaborate, if not always beautiful.

Dipus. See JERBOA.

Dir'ce, wife of Lycus, treated with great cruelty her husband's divorced wife Antiope. The sons of Zeus by Antiope took vengeance on their mother's foe by tying her to a wild bull, which dragged her about till she died—a subject represented in a famous antique statue group.

Dircks, HENRY, civil engineer, born at Liverpool, 26th August 1806, is known as the author of works on perpetual motion (1861) and electro-metallurgy; of *The Ghost* (in which he describes his invention, commonly called 'Pepper's Ghost') (1863), of a life of the Marquis of Worcester (1865), of *Inventions and Inventions* (1867), and of novels and essays. He died at Brighton, 17th September 1873.

Director, one of a number of persons appointed to conduct the affairs of joint-stock undertakings, such as banks, railways, water and gas companies, fire and life assurance companies, and various kinds of manufacturing and trading companies. See COMPANY.—Director is a name used by Catholics for a spiritual guide and confessor.

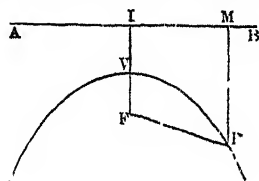

Directorium is the part of the Catholic church calendar which gives the order of the festivals and prescribes the services for the several days of the year.

Directory, a name applied to a board of guardians over any commercial, industrial, or scientific enterprise. Historically the name refers to the body of five men—Lépeaux, Letourneur, Rewbell, Barras, and Carnot—to whom the executive was intrusted in France after the downfall of the Terrorists, 26th October 1795 (5th Brumaire II.), and which lasted till the 9th November 1799 (18th Brumaire VIII.). Its corruption and incompetence made government impossible, and it was overturned by the Abbé Sieyès and Bonaparte, who established in its stead the consulate, soon itself to fall before the imperial ambition of Napoleon.

Directory for Public Worship, a code of regulations concerning the different parts of public worship, drawn up by the Westminster Assembly in 1644, ratified by the English parliament in the same year, and adopted by the General Assembly of the Church of Scotland on the 3d February, and by the Scottish parliament 'without a contrary voice,' on the 6th February 1645. It was on express order from both Houses of the English parliament that the Westminster Assembly addressed itself to the work of preparing this Directory, to supply the place of the Book of

Common Prayer, which had been abolished. In Scotland it was hailed as conducive to 'a happy unity and uniformity in religion among the kirks of Christ in these three kingdoms, united under one sovereign,' and to 'the corroboration of peace and love between the kingdoms.' Many of the regulations of the Directory are still complied with in all branches of the Presbyterian Church in Scotland, but in many things it has been generally departed from. The Directory is printed in vol. v. of Neale's *History of the Puritans*, and is usually appended to the Confession of Faith.

Directrix. If a point so move that its distance from a given fixed point is to its perpendicular distance from a fixed straight line in a constant ratio, it describes a conic section, of which the fixed straight line is termed the *directrix*, and the fixed point the *focus*. The constant ratio referred to is termed the *eccentricity*, and its magnitude determines the nature of the conic. Thus, if in the figure AB be the directrix and F the focus, if the point P move so that its distance from F is to its distance PM from AB in a constant ratio, then P will trace out a conic section, which will be an ellipse, parabola, or hyperbola, according as the ratio in question is less than, equal to, or greater than unity—i.e. as FP is less than, equal to, or greater than PM, or FV than VI.

Dirhem, a modification of the Greek *drachme* (see DRACHM), was the name under the calif. for a weight of silver equivalent to about forty-five grains, and was also used for precious stones and medicine in Arabia, Persia, Egypt, and Turkey. As a coin the value varied, but may be given at 5d. under the califs. In Turkey, the name dirhem has been given to the much smaller weight, the French gramme.

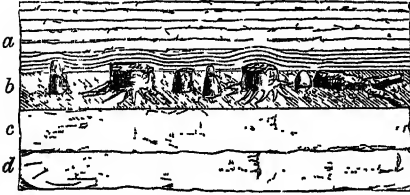

Dirk is a dagger. In the complete equipment of the Scottish Highlander, the *skean-dhu* ('black knife') is worn thrust inside the stocking.—The side-arm formerly worn by midshipmen and cadets of the royal navy when on duty was also called by this name. The weapon was a broad blade some 18 inches in length, furnished with a white fish-skin handle. This weapon, which superseded the sword in 1856, was clumsy, unsightly, and of small use for purposes of offence or defence.

Dirk Hartog Island, measuring 40 miles by 10, lies off the west coast of Australia, and, with Peron Peninsula to the south, incloses the Freycinet Inlet, while, with two smaller islands to the north, it forms the breastwork of Shark's Bay.

Dirschau (Polish *Tczew*), a manufacturing town of Poland, on the left bank of the Vistula, 20 miles SSE of Danzig. Road and railway bridges cross the Vistula. Polish from 1466 till 1772, but occupied by Gustavus Adolphus in 1626, West Prussian to 1918, Dirschau is now a railway junction, and has great railway works and sugar-factories. Pop. 36,000.

Dirt-beds, the quarrymen's name of several layers which occur in the Purbeck (q.v.) Beds, having the appearance of black dirt. They rest on the fresh-water limestones of the Purbeck, and consist of one principal layer, from 12 to 18 inches thick, and from two to four thinner layers. The substance is to a large extent a dark-brown or blackish earthy lignite, being the remains of an ancient vegetable soil. Through it are dispersed in considerable abundance rounded fragments of limestone (derived from the underlying bed) from

3 to 9 inches in diameter. Fossil Cycads (q.v.) were the predominant vegetable remains; they occupy their original upright position, having become fossil on the spots where they grew. The stumps stand erect for a height of from 1 to 3, or even more feet, and at distances from each other similar to what may be observed in a recent forest. Besides these, the dirt-bed contains the silicified stems of

Dirt-bed (Isle of Portland):

a, fresh-water calcareous slate, &c.; b, dirt-bed with stools of trees; c, fresh-water bituminous limestone, &c.; d, Portland stone, marine.

coniferous trees, laid prostrate, in fragments 3 or 4 feet in length. From the accompanying diagram it will be seen that the marine conditions under which the Jurassic limestone (Portland stone) was accumulated were succeeded by estuarine and fluviatile conditions, when the overlying calcareous beds forming the base of the Purbeck series were deposited. These beds were in like manner overspread with sandy carbonaceous clay, which eventually formed a land surface upon which grew a forest of cycads. Subsequently this forest was submerged and converted into a morass; and the trees decayed, and were eventually overturned by the force of wind or flood. Thereafter they were buried under newer accumulations of silt and calcareous mud, which now form the overlying fresh-water calcareous slate, &c.

Dis, the Roman equivalent of the Greek Pluto (q.v.). It is akin to *divus*, and originally denoted merely 'godhead' or 'deity.'

Disability, in Law, is either absolute, which wholly disables the person from doing any legal act—e.g. outlawry, excommunication, attainder, alienage—or partial, as infancy, lunacy, and drunkenness. For Catholic and Jewish disabilities, see CATHOLIC EMANCIPATION and JEWS.

Disbar, to degrade from the rank of barrister-at-law. This power is in England reposed in the benchers of the four Inns of Court. As the courts of law require that every barrister, before he is allowed to practise, must have been admitted to that office by one of the Inns of Court, so they will refuse to hear any one who has been deprived of his rank by the same authority. The power is rarely exercised, and only when the conduct of the offending party has been grossly irregular, one case of disbarring having occurred in 1862, and another in 1874. In the United States, the power to disbar is vested in the courts which have power to admit counsellors and attorneys to the bar.

In Scotland, the power to disbar rests in the Faculty of Advocates (see ADVOCATES).

Disc, in Botany, is a term applied with considerable vagueness by different authors to modified regions of the floral axis, particularly when forming a prominent ring supporting functional or rudimentary stamens, or bearing glands or nectary. See AXIS, FLOWER.

Disc, or DISCUS, a circular plate of stone or metal about 10 or 12 inches in diameter, made for throwing to a distance as an exercise of strength or dexterity. Disc-throwing was one of the principal gymnastic exercises of the ancient Greeks and

Romans, and was included in the *Pentathlon*, the five exercises (leaping, foot-racing, disc-throwing, spear-throwing, and wrestling) prescribed for athletes in the national games. The discus was held in the right hand, leaning against the forearm, and thrown in the manner of a quoit, the player throwing it farthest being the winner. The method is well shown in the celebrated statue of the Discobolus (the disc-thrower) by Myron (q.v.), of which several copies exist, one being in the British Museum. See also QUOITS, SCULPTURE.

Discalced, or DISCALCEATE, is the technical term for certain orders or sections of orders of friars and nuns bound by rule to go barefoot (from *dis*, and *calceus*, a shoe), especially amongst the Augustinians (q.v.), Carmelites (q.v.), Franciscans (q.v.), and Trinitarians (q.v.).

Discant. See DESCANT, COUNTERPOINT.

Discharge. See BANKRUPTCY; ELECTRICITY; ABSCESS, BOIL, PUS, SUPPURATION, ULCERS, WOUND.—In the British army discharge is a matter of right at the expiration of the period of service for which a soldier has enlisted, subject to his subsequent service in the reserve. In 1914 this was seven years with the colours, and five years in the reserve. He is entitled to a certificate stating his service, conduct, and cause of discharge, with a note of any qualifications he may have for special employment in civil life. If abroad when discharged he is also entitled to be sent home free of expense. At any time within three months of his enlistment he may claim, in peace-time, his discharge on payment of £10, but after that the consent of his commanding officer is necessary, and the payment may amount to as much as £25. He may be discharged at any time if convicted by the civil power, or if sentenced thereto by court martial to be 'discharged with ignominy' when considered 'incorrigible and worthless.'

In the case of seamen, each person discharged receives an official paper giving the particulars of the voyage, with his rating, &c. A seaman who is discharged abroad and becomes distressed may be sent home at the expense of the owner of his last ship, or at the expense of the Mercantile Marine Fund. Lascars discharged elsewhere than in India must be returned to the port they shipped at.

Disciples of Christ, a group of Christians found in various parts of the world who seek a restoration of the New Testament Christianity, and who advocate the union of all Christians on that basis. The names Churches of Christ and Christian Churches are also used. That of Campbellites, sometimes given in derision, they repudiate. Alexander Campbell (q.v.) was only one of a number who started independent movements, afterwards united.

Disciplina Arcani (Lat., 'Discipline of the Secret'), a term first employed by the German controversialists Tentzel and Schelstrate (1683-85) to denote a discipline of the early church, founded upon the words of Christ in Matt. vii. 6, and on 1 Cor. iii. 1-2, and Heb. v. 12-14, in virtue of which the knowledge of certain doctrines and the liberty of presence at certain rites connected with the most solemn mysteries of the Christian religion were withheld by the initiated from pagans and catechumens. Both unbelievers and catechumens were removed from the church at the commencement of what was afterwards called the *Missa Fidelium* (see LITURGY); such doctrines as regarded the sacraments of baptism and the eucharist were either not mentioned in the presence of these classes, or were referred to in enigmatical language, unintelligible to the uninitiated. This principle of reserve accounts for the absolute silence as to the eucharist

preserved in many early Apologies; the earliest indications of the discipline are met towards the close of the 2d century. After the 6th century, all need for it having disappeared, the practice was discontinued.

Discipline. See ARMY DISCIPLINE, CHURCH DISCIPLINE.

Discipline, BOOKS OF, the First and Second, embody the constitution and order of procedure of the Church of Scotland from the period of the Reformation. The *First Book of Discipline*, or the 'Police and Discipline of the Church,' was drawn up under a commission from the Privy-council of Scotland, in 1560, by John Knox and other four ministers—John Row, John Spottiswoode, John Winram, and John Douglas. These ministers, the same year, had prepared the doctrinal Confession of Faith of the church, which was inscribed among the acts of parliament as a statute of the realm; but for the practical government and discipline of the church, a form of order more elaborate than that imported from Geneva was required, and this was provided in the *First Book of Discipline*. It was approved by the General Assembly, but on being presented to the Privy-council several members manifested opposition to some things in the book, and it was not ratified by the council as such. Most of the members, however, subscribed it, and pledged themselves to set forward its regulations. These had reference principally to (1) the providing of ministers for the numerous congregations all over the country, but as ministers were then few in number, the temporary expedient was resorted to of appointing readers, exhorters, and superintendents; (2) the order of public worship and dispensation of the sacraments; (3) the establishment of schools in every parish, and of colleges in every 'notable' town; (4) the provision to be made for the support of ministers, schoolmasters, and the poor; and (5) the mode of dealing with offenders against the laws of the church. Subscription of the *First Book of Discipline* was required of all ministers of the church before admission to office.

On account of the urgent need which was felt for such a book, it was prepared with haste, and several important matters were soon found to have been omitted. So early as 1563 a revised book of discipline was desiderated, but in consequence of the harassments of civil dissensions the revision was postponed. In 1575 a committee was appointed to take charge of the matter. Of this committee Andrew Melville was a prominent member, and the result of its labours was—

The *Second Book of Discipline*, or 'Heidis and Conclusions of the Police of the Kirk.' This was received and adopted by the General Assembly in 1578, and in 1581 that venerable body ordered that it should be engrossed at length in their register, and that copies should be taken by all the presbyteries of the church. Efforts were made to have it ratified by parliament at the time, but without success. It was, however, on the basis of the *Second Book of Discipline* that the constitution of the Church of Scotland was settled by the Scots parliament in 1592, and again in 1690. It is sworn to in the National Covenant, and was ratified by the General Assembly in 1638 as well as in 1645, when the Assembly received and adopted the 'Form of Church Government' prepared by the Westminster Assembly of Divines. It was not intended that the *Second Book of Discipline* should annul or supersede the first, but rather that it might amplify and qualify its regulations. Profiting by the experience gained under the operation of the first book, the church by the second abolished the temporary expedients to which the exigencies of the case had obliged them formerly to resort; and in the new book the Pres-

byterian system was established on the broad and solid platform on which it stands to the present day. Both Books of Discipline are still standards in the Church of Scotland, and also in some of the other Presbyterian bodies which have seceded from it.

Disco, an island on the west coast of Greenland, under the parallel of 70° N. It is mountainous, reaching a height of 3000 feet, and has a total length of about 90 miles, and contains much excellent coal. Godhavn harbour is on the south coast.

Disco-bolus. See DISC.

Discomycetes. See FUNGI.

Discontinuance. See ABANDONMENT.

Discord is a combination of notes which leaves the ear unsatisfied unless it is followed by further combination, usually a concord, which is termed the *resolution* of the discord. See MUSIC.

Discount is an abatement made when a debt or bill is paid before its due date. True discount in arithmetic is the difference between the amount of a future payment and its present value. Thus if £105 be due one year hence, the discount (at 5 per cent.) will be £5, and the present value £100; for £100 will amount to exactly £105 in one year at 5 per cent. But the practice of bankers and bill-discounters, which is sanctioned by mercantile usage, is to charge *interest* on the principal sum for the period discounted—i.e. from the date when the cash is advanced till the date when payment is due. In the above example, a banker would charge £5, 5s. for discounting a bill of £105 due one year hence, at 5 per cent.; so that he gets an advantage of 5 per cent. over the arithmetical discount, which, as we have seen, is £5. The rate of discount varies according to circumstances, the official bank-rate being usually higher than that obtainable in the market. In the case of foreign bills, instead of a fixed charge being made for discount, the usual practice is to quote a rate of exchange lower than the current rate, so as to cover this charge. The term discount is also applied to the depreciation in value of stock, &c. Thus if a loan is issued at the price of £90 cash for a nominal £100, it is said to be at a discount of 10 per cent. Shopkeepers often grant a discount on prompt payment of an account, or as an encouragement to further dealings.

Discovery. The English common law did not permit a party to an action to be a witness; but a court of equity would compel him to discover or disclose facts which his opponent had a right to know. Parties may now give evidence; but discovery is granted before trial, in any division of the High Court, of such facts or documents as a party requires in order to frame his own case. But a party is not permitted, by means of discovery, to obtain a premature disclosure of the case of his opponent. In the United States, the rules of practice are substantially the same as those of the English courts.

Disease, according to its literal construction, a state of *dis-ease*, or absence of the condition of health, in which all the faculties and organs of the body and mind work together harmoniously and without sensible disturbance. It is common to treat of disease as being *functional* or *organic*—i.e. evidenced by changes of function or of structure; but function and structure are so closely allied in fact and in nature, that the more this distinction is examined, the more vague and impalpable it becomes, and it can therefore only be kept up as a provisional and conventional arrangement.

A classification of diseases is a necessary preliminary to any general inquiry regarding them; particularly to such statistical methods as are involved in the tabulation or causes of death by registrars,

in returns of hospitals, and of the medical departments of the army and navy, &c. The standard authority in Britain as regards diseases affecting man is the *Nomenclature of Diseases*, published under the supervision of the Royal College of Physicians of London. We give a short outline of the arrangement adopted in the fifth edition (1918). The list includes nearly 900 names of diseases, besides the various poisons and injuries specified, which extend it to more than 1200.

I. Diseases caused by infection, including the common febrile maladies like chicken-pox, diphtheria, enteric fever, erysipelas, influenza, measles, pneumonia, scarlatina, small-pox, tuberculosis; less frequent conditions like malaria, leprosy, meningitis, plague, tetanus, yellow fever; venereal diseases—syphilis and gonorrhoea; and diseases usually affecting only animals—e.g. anthrax, glanders, hydrophobia.

II. Diseases of the nervous system. These are divided into three sections. (1) Diseases of the nerves, spinal cord, brain and their membranes. (2) Diseases which are names for groups of symptoms of which the cause is not fully known—e.g. shaking palsy, chorea, spasmodic wryneck, and other habit spasms like writers' cramp, neuralgia, convulsions, epilepsy, migraine, hysteria, catalepsy, neurasthenia. (3) Mental diseases. Some of these are developmental, like idiocy; some are evidences of disordered function of the brain, like mania, melancholia, delusional insanity; in another group the symptoms are due to infective, toxic, or other general conditions—e.g. delirium, exhaustion insanity, alcoholic insanity.

III. Diseases of the eye.

IV. Diseases of the ear.

V. Diseases of the nose.

VI. Diseases of the circulatory system. This includes (1) diseases of the heart, like pericarditis, endocarditis, degeneration of the heart muscle, and disease of the valves; (2) disordered action of the heart; and (3) disease of the blood-vessels—e.g. arterio-sclerosis, aneurysm, and phlebitis.

VII. Diseases of the blood, such as anæmia, hæmophilia, and leucocythæmia.

VIII. Diseases of the spleen.

IX. Diseases of the lymphatic system—e.g. inflammation of the glands, lymphangitis.

X. Diseases of the glands of internal secretion, including those of the thymus, thyroid, adrenals, and pituitary gland.

XI. Diseases of the breast, such as inflammation, malignant growths.

XII. Diseases of the respiratory system, including those of the larynx, trachea, bronchi, lung, and pleura.

XIII. Diseases of the teeth and gums.

XIV. Diseases of the digestive system, including those of the mouth, tonsils, salivary glands, gullet, stomach, intestines, pancreas, liver, and peritoneum.

XV. Diseases due to disorders of nutrition—e.g. obesity, scurvy, gout, and diabetes.

XVI. Diseases of the generative system, male and female, including affections connected with pregnancy.

XVII. Diseases of the organs of locomotion, including those of bone, joints, spine, muscles, tendons, and deformities.

XVIII. Diseases of the skin.

XIX. Diseases of the urinary organs.

XX. Injuries general and local. Also there is an appendix containing lists of surgical operations, tumours, malformations, poisons, and parasites.

Diseased Meat. See FOOD, MEAT, PTOMAINES, PYÆMIA.

Dis'entis, a Swiss health-resort in the Grisons, on the Father Rhine, 39 miles SW. of Coire. Its abbey was founded in the 7th century.

Disestablishment. See STATE CHURCH.

Dishonour. See BILL OF EXCHANGE.

Disinfectants are, strictly speaking, agents which can prevent infectious diseases from spreading, by destroying their specific poisons. The term is, however, often applied to all substances which destroy or neutralise bad odours, though not all such have the power of counteracting infection. Many infectious diseases have now been proved, and all are believed, like Putrefaction (q.v.), to be due to special micro-organisms which are found in different parts of the body, and are communicable in different ways in different diseases (see GERM THEORY). The action of disinfectants is therefore exactly analogous to that of Antiseptics (q.v.), and consists in the destruction of low forms of life. But the two classes do not necessarily correspond, as the same substance may have unequal poisonous effects on different forms. It is of the utmost importance to discover the conditions which are most deadly to each disease-poison, and to apply them, if possible, within as well as without the diseased body. But little has yet been done in this direction.

Carbolic acid, which probably stands highest in popular esteem as a disinfectant, is undoubtedly one in the strict sense. It is not, however, in the very dilute state that it can act thus, and it is necessary to use it comparatively concentrated before good can result. Thus a 2 per cent. solution, mixed with vaccine lymph, completely destroys it, but a more dilute solution has almost no action on it. As a deodoriser, carbolic acid is not so energetic as chlorine and permanganate of potash, but there is this great difference, that while the acid destroys the organic substances which give rise to the offensive odour, the others mainly attack the odour itself, and therefore require to be applied frequently if perfect sweetness is desired. Thus a piece of putrid flesh is not rendered odourless so quickly by carbolic acid as by the other substances named, but one thorough application of it will prevent the recurrence of decay, a property not possessed by the others.

The vapour of carbolic acid is not a disinfectant at ordinary temperatures, as bacilli are not destroyed, even when exposed to it for six weeks. It is therefore evident that the mere exposure of that substance in vessels is of no service in disinfecting a room. It is curious that carbolic acid dissolved in oil or alcohol has no antiseptic action whatever, but that if water be present, as in the case of a wound, it acts powerfully.

Sulphurous acid has long been in repute, both in the form of solution and in the gaseous state. Experiments on cultivated bacilli seem to prove that, while in the liquid state it is a powerful disinfectant, it has little action either as dry gas or along with water vapour.

Mercury salts, such as the perchloride (corrosive sublimate) and biniodide, are powerful disinfectants, and are much used at present as antiseptics. For general domestic use, however, they have great disadvantages. The former attacks metals, and therefore ruins many pipes, while it is very rapidly neutralised by the presence of organic matter, especially where sulphuretted hydrogen has been developed. The biniodide is preferable, but neither of them is completely satisfactory. Of all the long list of popular disinfectants, chlorine, bromine, iodine, osmic acid, permanganate of potassium and of sodium, and corrosive sublimate seem to be the most certain and rapid, but all of these are open to objections. The employment of fumigating pastilles, burning brown paper, camphor,

benzoin, mastic, amber, lavender, and other odiferous substances, is meily serviceable in cloaking over the offensive, fetid, and hurtful gases, and should never be resorted to unless in conjunction with the use of other agents possessing the properties of true disinfectants. For disinfecting clothes, bedding, &c., the most satisfactory treatment is heat. They may be heated to 250° F. without harm.

It will be seen from the foregoing that a general, satisfactory disinfectant is still a desideratum, and that even those in most use require favourable conditions, and a more lavish application than is generally forthcoming.

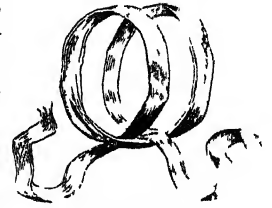

Dislocation consists in the displacement of one bone from another with which it forms a joint (*put out of joint* being the popular expression). Dislocations are generally the result of sudden accident, but may be the result of disease, or may be congenital. The displacement may be *partial* or *complete*; and surgeons classify their cases into *simple* dislocations, when the skin remains unbroken, and *compound*, when there is a wound by which the external air may communicate with the joint. Occasionally, in addition to the dislocation, there are fractures of the bones, or lacerations of important blood-vessels in the neighbourhood, or other injuries; it is then termed a *complicated* dislocation. Dislocation is a rare accident in infancy and old age, because in the former the joint-ends of the bones are very flexible, and yield to violence; while the aged skeleton is so rigid that the brittle bones fracture under force that would drive mature and stronger ones out of their sockets. Dislocations are most frequent between the ages of twenty and sixty. Persons with weak muscles, and lax, long ligaments, or those in whom the latter have been softened by inflammation of the joint, are predisposed to dislocation. The shoulder is far more frequently dislocated than any other joint in the body; in the lower extremity the hip most often suffers.

General Symptoms of a Dislocation.—After a blow, fall, or violent muscular exertion, a limb is found to have lost its natural mobility at the injured joint, though there may be some movement in abnormal directions under examination; there is some pain, and the shape of the part is changed; but soon swelling ensues, and every distinctive mark about it is obscured. If left alone, or merely treated as an inflamed joint, the swelling gradually subsides; but the immobility continues, the limb is crippled for months or years, when at last nature forms a new socket for the end of the bone, and some amount of useful motion is recovered. The proper shape of the part is never restored, but remains an eyesore to the patient, and a disgrace to the surgeon.

The general treatment of dislocations consists in their *reduction*, or bringing the displaced bone back into its place. Its return is opposed by the muscles attached to it, these being stimulated to contraction by the pain of the operation, and by the ligaments surrounding the joint, which generally fix it in its unnatural position. Sometimes it is necessary to remove this spasm of the muscles, and in former days bleeding from the arm, emetics, the warm bath, &c., were generally made use of; nowadays chloroform or ether attains the same ends, and renders the treatment of dislocations much more simple and humane than before the introduction of anaesthetics.

Till about the year 1870, reduction of dislocations was generally effected by means of *extension*. When the surgeon is about to reduce a dislocation in this way, he fastens the part of the limb above the displaced bone or the trunk, so as to afford him *counter-extension*; he then pulls on the limb either with his hands, or with a bandage or skein of worsted attached to it. This he fixes

by making a *clove-hitch* on it—i.e. two loops in opposite directions laid together (see figure), and slipping it up the limb to the point desired, where a wet bandage has previously been applied to give a firmer hold. In old-standing cases in the larger joints, the hands grew weary before the extension had been kept up sufficiently long; and it was often found necessary to adapt pulleys to draw upon the *clove-hitch*, as with them the traction could be made as strong as the surgeon desired. Sudden, forcible pulling is useless and hurtful, the main object being merely to tire out the muscles which resist the attempts at reduction; when they are exhausted, the bone will generally slip back into its place with an audible snap.

Clove-hitch.

Of late years, however, reduction by extension has been to a very large extent given up in consequence of the general adoption of reduction by *manipulation*. This method, known it seems from ancient times, but curiously neglected, consists in executing certain complex movements of the dislocated limb which effect the return of the displaced bone to its socket by ingeniously utilising its unruptured attachments and evading the opposition of the muscles, by fraud rather than by force. It is particularly applicable to the hip, which, as it is commanded by the strongest mass of muscles in the body, always presented the most formidable obstacles to the old method. The first paper on this subject which attracted general attention was by Dr Reid of Rochester, U.S. (1851); and in 1860 Professor Bigelow of Boston published a careful and exhaustive discussion of injuries to the hip, with such full and clear directions for the manipulation method, as to secure its general adoption in the case of this joint by surgeons in this country as well as in America. The method, however, had been described and used in France and elsewhere, though with less care and precision, in the earlier half of the 19th century.

The class of persons called *Bonesetters* (q.v.) almost invariably give the opinion, in cases of stiff joints brought to them, whether as the result of disease or injury, that 'a bone is out;' and if a regular practitioner has been treating the case, further say that he has failed to detect it. They are almost invariably wrong in this opinion; for there are very few cases of dislocation not easily recognisable, at all events after the swelling following the accident has subsided. When, however, the forcible movements they employ succeed in improving the condition of the joint, their view is naturally adopted by the patient and his friends that they have replaced the 'bone.' In most cases of this kind, what really takes place is the rupture of Adhesions (q.v.) remaining after sprains or bruises in the neighbourhood which limited and rendered painful the movements of the joint.

Whenever a dislocation occurs, the nearest medical man should be summoned, even should the mere displacement be rectified at once, because no such accident can occur without some tearing of the soft parts, and it will depend on the after-treatment whether the joint will ever become useful again or not. It must also be remembered that the sooner a dislocation is reduced the easier is the reduction. Since the introduction of anaesthesia, however, and the subcutaneous division of tissues, many ancient cases may be improved, and many crippled limbs restored to usefulness.

Dismal Swamp, measuring 30 miles from north to south by 10 in breadth, lies chiefly in Virginia, but partly in North Carolina. In the centre is Lake Drummond, about 6 miles broad; elsewhere its dense growth of cypress and cedar has been greatly thinned, and part of the region has been reclaimed. The tract is intersected by a canal connecting Chesapeake Bay and Albemarle Sound.

Dismas, the Catholic traditional name of the penitent thief, the impenitent being *Gestas*.

Dismembered. See *DEMEMBERÉ*.

Disorderly House. See *PROSTITUTION*.

Dispensaries are institutions for supplying the poor with medical advice and medicines. They are of two kinds, provident and free. The first are excellent institutions for encouraging habits of thrift, and training the poor not to depend on medical charity. The members of provident dispensaries pay a few pence weekly, which entitles them and their families to advice and medicine when necessary. The medical officer attends at the dispensary every morning to prescribe for those who call; after a certain hour he goes the round of the district, and visits those who are too ill to attend at the dispensary. It is often necessary in starting these institutions that there should be certain honorary members paying a subscription that will cover the expense of the building and drugs; the pence of the ordinary members should cover the officer's fee. Free dispensaries much resemble the out-patient department of hospitals, without the advantage of having wards to which the worst cases can be relegated. In Ireland, since 1851, when the Irish Dispensaries Act was passed, every district has a dispensary, where the poor are entitled to advice and medicine on presenting tickets, which are distributed by relieving officers, guardians, &c. The first dispensary founded in Britain was the Royal General Dispensary, Bartholomew Close, London, opened in 1770. See *HOSPITAL*.

Dispensation, the remission of a law in a particular case by competent authority. It is generally admitted, even by the most extreme of the Roman Catholic canonists, that no dispensation from the natural and moral law can be granted by any human power (Liguori, *Theol. Moral.* vi. 1119). On the other hand, it is generally held that the pope can dispense from oaths and vows, because in this case the obligation is founded upon an act of free human will, which the pope may annul. Further, with regard to positive divine laws—i.e. with regard to things which are not essentially good or evil, but which God has been pleased to command or prohibit by special revelation, it is held that the pope may declare that a particular case does not really fall under the law. For the rest, the pope may dispense from the general laws of the church. He may, e.g., allow a man to marry his deceased wife's sister, for the prohibition is derived solely from the church law, the Mosaic code, as such, having no authority among Christians; and, therefore, the supreme authority in the church may dispense from it. Of such dispensations the most noteworthy was that allowing Henry VIII. to marry Catharine of Aragon. In the earlier periods of church history, bishops and provincial councils also dispensed from the general law of the church, but since the time of Innocent III. the pope alone can do so as a general rule, and bishops only in certain cases mentioned by the canon law, unless, indeed, they act as papal delegates. Papal dispensations, if they are of a public nature, are granted through the Apostolic Dataria; if they concern the secret tribunal of conscience, through the

Penitentiary. Bishops, in the exercise of their ordinary power, dispense from the proclamation of bans, from certain 'irregularities' which impede ordination, from clerical residence, &c. Many canonists add that bishops may dispense in pressing cases, where recourse to the pope is impossible, and the approval of the pope may be certainly presumed. Besides this, in virtue of faculties which may be obtained from the pope for five years at a time, a bishop can dispense from the law of abstinence from flesh-meat, from all the ecclesiastical impediments which make marriage unlawful, and from some of those which nullify it, from most 'simple' vows, &c. The vicar-general can dispense in very few cases, except by commission of the bishop. During the vacancy of a see, the bishop's ordinary power of dispensation passes first to the chapter and then to the vicar-capitular. Parish priests, &c. have no power of dispensation. The Council of Trent (Sess. xxv. c. 18) requires that dispensations be given only for a 'just and urgent' cause, after full consideration, and gratis. The last word, however, does not exclude the payment of the statutory fees.

In the English Church, papal dispensations were swept away by 25 Henry VIII. chap. 21. The Archbishop of Canterbury grants special licenses for marriage, and the bishop of the diocese may dispense a clergyman from residence, or grant him leave to hold more than one living.

In civil matters, the dispensing power of the crown, grossly abused by James II., was abolished by the Bill of Rights, and the sovereign's power of pardoning criminals is the sole form of it which is left.

The term dispensation is also used in Mosaic or Jewish dispensation, Christian or gospel dispensation, for the systems of rights and duties imposed by Providence under the Old Testament economy and that of the New respectively.

Dispersion. The refractive index of a transparent medium is different for different kinds of light. Thus, when white light passes through a given prism, the rays of different refrangibility of which it is composed are bent by different amounts from their original common direction. They are said to be *dispersed*. The dispersion for the given prism depends upon the difference of the refractive indices of the extreme rays of the visible spectrum. It varies with the substance and the angle of the prism. The relative breadth of any two parts of the spectrum varies with the substance of the prism. This constitutes the so-called *irrationality* of dispersion. In general, rays of short wavelength are more refracted than rays of long wavelength, but in some refracting media this law breaks down in part. This is known as *anomalous dispersion*. The term *false dispersion* is applied to the scattering of light by reflection from motes suspended in a transparent medium. See *LIGHT*.

Displayed, a heraldic term used to describe the position of an eagle or other bird with its wings expanded.

Disposition, in the Law of Scotland, is a deed of conveyance and alienation, which transfers a right to property, either heritable or movable. The most common form of disposition is that which conveys heritage from a seller to a purchaser. Dispositions of movable subjects are also known in practice. Another form of disposition is the general disposition and settlement, which is used to settle the whole succession to an estate including both heritable and movable property. When such a succession is settled by a conveyance to trustees with specified powers, the deed is called a trust-disposition and settlement. All these deeds have a form, similar, indeed, but varying according to

the nature of the property conveyed and its destination. For disposition in security, see **HERITABLE SECURITIES**.

Disputation, an exercise of logical and dialectic skill, in which one party advanced an argument, and the other sought to refute it. Challenges to such exercises were often issued—e.g. at Paris in 1577, by the 'Admirable' Crichton. Memorable religious disputations were those between Knox and Kennedy (1562), and between Laud and Fisher the Jesuit (1623). The practice survives as an academic form.

D'Israeli, ISAAC, man of letters, was born at Enfield in 1766, the only son of Benjamin D'Israeli (1730-1816), a Jewish merchant, who in 1801 was made an English citizen. Isaac was educated at a school near Enfield, and for two years at Amsterdam under a freethinking tutor; in 1782 he returned home, bent on authorship. He published two volumes of verse and seven romances; but his *Curiosities of Literature* (6 vols. 1791-1834), the fruit of much reading at the British Museum, showed his forte to lie not in creative literature, but in the illustration of history and literary character. To this he devoted himself with much success, his chief other books being *Calamities of Authors* (1812-13); *Quarrels of Authors* (1814); *Commentaries on the Life and Reign of Charles I.* (5 vols. 1828-30), which won him the honour of D.C.L. from Oxford; and *Amenities of Literature* (1840). Though somewhat slipshod and inaccurate, they are pleasant, readable works, and gained for their author the friendship and admiration of Byron, Scott, Southey, Moore, Bulwer Lytton, and Rogers, the last of whom observed, with his usual sneer: 'There's a man with only half an intellect who writes books that must live.' In 1802 Isaac D'Israeli married Maria Basevi (1775-1847), and by her he had one daughter and four sons, the eldest the famous statesman, Lord Beaconsfield (q.v.). Always a lax observer of the Jewish faith, he broke with the synagogue in 1817, and had all his children baptised. In 1829 he removed from Bloomsbury Square to Bradenham House, Bucks, where, after nine years of blindness, he died 19th January 1848. See, prefixed to the 1849 edition of the *Curiosities*, a memoir by Lord Beaconsfield, who also published a collected edition of his works (7 vols. 1858-59).

Disruption. See **FREE CHURCH OF SCOTLAND**.

Diss, an urban district of Norfolk, on a rising-ground above a mere of 5 acres, 19 miles SSW. of Norwich. It has a good Perpendicular church, with a fine peal of bells, of which, early in the 16th century, John Skelton was the unholy rector. The old weaving trade has long been a thing of the past. Pop. (1851) 2419; (1921) 3513.

Dissection. See **ANATOMY**.

Dissemination. See **GEOGRAPHICAL DISTRIBUTION**.

Dissenters. See **NONCONFORMISTS**.

Dissepiment, in Botany, the partition between two Carpels (q.v.) in an ovary or fruit composed of a number of carpels. See **OVARY**.

Dissidents is a general term for dissenters in various countries, but has been specially used of the Polish non-Catholics or *dissidentes*—Lutherans, Calvinists, Greeks, and Armenians (not, however, including Anabaptists or Socinians).

Dissipation. See **ENERGY**.

Dissociation. See **ELECTRICITY**, **MOLECULE**, **PHYSICAL CHEMISTRY**, and for mental dissociation, **HALLUCINATIONS**, **HYSTERIA**.

Dissonance is a combination of musical sounds which produces beats. See **SOUND**, **MUSIC**.

Distaff, the staff on which the flax or wool is fastened, and from which the thread is drawn in spinning by hand. See **SPINNING**.

Distemper (Fr. *détrempe*, from *détremper*, 'to moisten'; Ital. *tempera*), a method of painting in which opaque colours are mixed with water and such glutinous substances as size, white of egg, the sap of the fig-tree, &c., and applied to a smooth surface of dry plaster or *gesso*, spread commonly upon wood, but sometimes upon canvas. It is a process of great antiquity; and it was the ordinary method by which the early Italian and Flemish painters produced their easel-pictures (see **PAINTING**). Such works, when they have been afterwards oiled or treated with an oil-varnish, are frequently difficult to distinguish from oil-pictures. It is to be distinguished from *Fresco* (q.v.), in which the colours are applied to a fresh damp surface of plaster, with which they become incorporated. Distemper is now most commonly employed for scene-painting.

Distemper is a contagious and infectious disease of dogs, and perhaps of all animals of the canine family, sometimes met with, it is said, in the cat. The causal organism is not known. As a rule, it occurs only once in a lifetime, runs a definite course, is accompanied by low fever and debility, and is most successfully treated by good nursing and attention to diet and regimen. It has been divided into five different forms—catarrhal, pneumonic, intestinal, hepatic (known as yellows), and nervous, perhaps really different diseases. The catarrhal always accompanies and frequently precedes the other forms. The eyes are red or yellow, weak, and watery; the nose dry and hot; draughts of air or movements of the animal readily excite sneezing or cough; there is dullness, fever, and loss of appetite. The thickened slimy mucus which the inflamed membrane after some days secretes, accumulates about the eyes and nostrils, and lodging in the bronchial tubes, prevents the free access of air and the proper purification of the blood. Hence ensue distressed breathing, increasing weakness, and symptoms of nervous disturbance, such as staggering gait, chorea, and fits. All dogs are liable to distemper, but the delicate and highly bred varieties suffer most severely, and amongst them the mortality is very great. Bleeding, physicking, and all irritating and reducing remedies, must be carefully avoided, and a good dry bed in a comfortable airy place provided. The stomach, if overloaded, should be relieved of its contents by an emetic, which, for an ordinary sized English terrier, may consist of two grains each of tartar emetic and ipecacuanha, with eight or ten grains of common salt, given in a wine-glassful of tepid water. If no effect is produced, the dose must be repeated in twenty minutes. Constipation, if present, should be corrected by half an ounce each of castor and olive oil, to which, in large dogs, a few grains of gray powder is a useful addition. The febrile symptoms, if acute, may be alleviated by giving four times daily, in cold water, five drops of laudanum, and five grains each of nitre and hyposulphite of soda. Distressed breathing may be relieved by applying to the chest and sides, for an hour or two continuously, a thick flannel cloth, wrung at short intervals out of hot water. The throat may also be rubbed with hartshorn and oil, and the nostrils sponged and steamed occasionally. Give frequently, and in small quantities at a time, milk and bread, or any other such simple and digestible food; and when recovery is tardy, and weakness ensues, endeavour by nursing, tonics, and stimulants, to support the strength. The term is sometimes applied to *Influenza* in horses, and epizootic *Pleuro-pneumonia* (q.v.) in cattle.

Distich (Gr. *distichos*, 'consisting of two rows') is the classical name given to any two lines, but especially to a hexameter and pentameter, making complete sense, the character of which is seen in the following well-known example by Schiller:

Im Hexameter steigt des Springquells flüssige Saule,
Im Pentameter drauf fällt sie melodisch herab,

which was thus Englished by Coleridge:

In the hexameter rises the fountain's silvery column,
In the pentameter aye falling in melody back

It was much used by the Greeks and Romans as a vehicle for the expression of single thoughts and sentiments; and hence became almost exclusively employed for the classical epigram. The greater poets of modern Germany, as Goethe and Schiller, have also shown a fondness for the distich, and remarkable skill in its use. A collection of moral maxims in Latin, ascribed to a certain Dionysius Cato (q.v.), is called *Disticha*, and was highly popular during the middle ages.

Distillation is the name given to the process of applying heat to a liquid, or, it may be, a solid, in order that certain constituents may pass away in vapour, and, by suitable arrangements, be obtained in the form of a liquid. When the vapour does not condense as a liquid, but only as a fine dust or flour, the process is called *Sublimation* (q.v.). The natural evaporation of water, by the heat of the sun, or warm air currents, the ascent of the vapour into the colder regions of the atmosphere, and the condensation there into clouds and mists, with the subsequent rain-shower, form together the grandest example of distillation. The apparatus for artificial distillation essentially consists of three parts, the Still (or RETORT, q.v.), Condenser, and Receiver. The still is made of glass, copper, iron, or earthenware, according to the nature of the substances to be placed in it. In experimental chemical work, glass is almost the only material admissible, while in the preparation of alcohol from grain, copper-stills are commonly employed. The condenser is made in an infinity of forms, the object being to condense the vapours disengaged from the still as rapidly and effectually as possible. For this purpose it is important that the condenser shall expose a large surface to the cooling medium, water or air. Owing to its rapidity in conducting heat, and the thinness of pipes made of copper, this metal is generally employed in the construction of condensers. Whatever the form, the principle is the same—viz. that the hot vapours pass through a tube or vessel surrounded with cold water, which running in a constant stream, passes away more or less warm after it has done its work. The receiver merely consists of a suitable vessel in which to receive the *distillate*. As the forms of apparatus are capable of infinite variety, so the conditions of distillation are innumerable; the best defined types being Fractional Distillation, Destructive Distillation, and Distillation in Vacuo.

In *Fractional Distillation* a mixture of liquids having different boiling-points is put in the still and heat is applied. If the vapours were allowed to pass over together and the distillate to be received in a single receiver, it is evident that nothing would be gained. If, however, the temperature be raised very slowly, and especially if the vapour requires to rise through a high head, or tube, before passing into the condenser, it will be found that the more volatile liquids pass over first in a state of comparative purity, and the others follow as the heat is increased. Several types of fractionating heads or columns are used in the laboratory, all with constrictions or interceptors of some type, to pass vapour over previously condensed vapour. If the receiver be frequently

changed, *fractions* or portions of liquid are obtained, corresponding to the different substances present. For example, if a mixture of glycerine, water, alcohol, chloroform, and ether were distilled, the ether would distil first, then the chloroform, next the alcohol, and lastly, the water, while nearly all the glycerine would be left behind.

Destructive Distillation, or Dry Distillation as it is sometimes called, is best exemplified when coal is heated in an iron still or *retort*, as in the manufacture of gas. Now, in coal there are only traces of moisture capable of distillation, but when strongly heated, the coal is destroyed, or *decomposed*, and a large number of substances distil over, some of which, like lighting gas, are permanently in the gaseous state, others like Creasote (q.v.) are liquid, while others, such as naphthalene, are solid bodies at the ordinary temperature. Here no distillation takes place until the substance heated is destroyed, hence the term destructive distillation. Further examples are the distillation of wood in close vessels, at a red heat, when charcoal is left in the vessel, and wood-vinegar, wood-spirit, tar, &c. pass over in vapour, and are condensed; and the heating of bones in similar retorts, when animal charcoal is left in the retort, and Dippel's animal oil distils over. See CHARCOAL, COAL-TAR, and DIPPel's ANIMAL OIL.

Distillation in Vacuo.—When water is heated in a kettle it eventually boils, and if a thermometer be plunged into it, the mercury is seen to remain stationary at a temperature of about 212° (100° C.). It will be noticed, however, that when the barometer is low, the temperature of the boiling water is somewhat below 212° (100° C.), and that when the barometer is very high, the temperature is also high. On the summit of Mont Blanc, it is found that water boils at about 180° (82° C.); while in a vessel from which the air has been removed by an air-pump, it continues to boil even when the temperature falls down to the freezing-point (see BOILING.) There are many substances which are injured by heat, such as extract of malt and sugar, and when solutions of these bodies require to be evaporated on a large scale, they are always distilled *in vacuo*, so that the water may be removed without unduly heating the vessel.

There is another very interesting method of distillation whereby liquids which, alone, cannot be distilled without decomposition, are made to distil in presence of the vapour of some other liquid. Thus, glycerine is not, practically speaking, capable of being distilled, but when heated with high-pressure steam, it readily distils over, and can thus be purified. The great object of distillation is purification, and in the manufacture of the fragrant volatile oils of lemon, lavender, &c., it is necessary to distil them along with water so as to avoid overheating of the oils, and consequent injury. Not only is the flavour improved by this treatment, but they distil at a lower temperature along with water than when alone. The term distillation in excise language refers to the distillation of alcohol alone. For information on this subject, see FERMENTATION, ALCOHOL, BRANDY, GIN, SPIRITS, and especially WHISKY; under which latter head the subject of the duties payable and of illicit distillation are also treated.

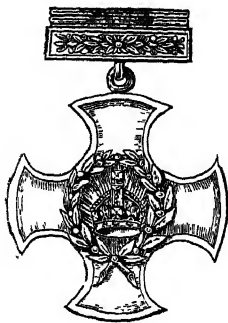

Distilled Water is the condensed product obtained by the distillation of water. All natural waters, even rain-water, contain certain saline matters (common salt, &c.) in a state of solution, from which they can only be completely freed by the process of distillation. The characteristics of distilled water are, that it possesses a mawkish, insipid taste, without odour or colour, and when evaporated to dryness in a vessel, it ought to leave no residue. Unless very specially prepared, it is sure to contain

traces of free ammonia, and, when this is the case, it is liable to form a green vegetable growth in any bottle containing it. The other properties of distilled water will be noticed under WATER.

Distilled Waters is the name for what is obtained by distilling water along with the parts of plants containing essential oils. Rose-water and lavender-water are familiar examples.

Distinguished Service Order. This order was instituted by royal warrant on 6th September 1886 for rewarding the distinguished services of naval and military officers who have been honourably mentioned in despatches. Foreign officers who

have been associated with British forces in naval and military operations are eligible as honorary members of the order. The Companions of the order rank immediately after those of the Order of the British Empire. The Sovereign is head of the order. The badge consists of a gold cross, enamelled white, edged gold, having on one side in the centre, within a wreath of laurel enamelled green, the imperial

crown in gold upon a red enamelled ground, and on the reverse, within a similar wreath and on a similar red ground, the royal cipher; and it is suspended from the left breast by a red riband, edged blue, of one inch in width.

Distomum. See FLUKE.

Distortion. When any body is subjected to the action of a deforming force, or stress, the corresponding deformation, or strain, is sometimes termed a *distortion*. In this limited sense the term is frequently used in treatises on elasticity. The definition would almost indicate some relation between a distortion and the force causing it. Such relation was first given by Hooke (1635-1703) in the law which bears his name: Distortion is proportional to the distorting force. Thus, for example, if a plank of wood supported at each end be deflected at the middle through a certain space by the placing there of a given weight, twice the weight will give twice the deflection, and so on. See ELASTICITY.

Distrain. See DISTRESS.

Distress, in English law, is the common-law remedy by which a man may enforce payment of rent or other duties, or may impound another's cattle trespassing upon his land. Distress is defined as the taking of a personal chattel out of the possession of the wrong-doer into the custody of the party injured, without process of law. Distress was formerly an incident of all feudal services, such as suit of court, and fealty: it was also used to compel obedience to the orders of a court leet. In modern days, distress is practically enforced chiefly for non-payment of rent, for non-payment of rates and penalties, and upon cattle straying upon land not belonging to their owner. Cattle so straying may be impounded and retained as security till their owner make satisfaction. Distress for rates and penalties is allowed by the statutes imposing them. In this species of distress, and distress for non-payment of rent, the articles are not merely kept as security, but may be sold to pay the amount due. Whatever goods the landlord finds on the premises, even goods belonging to a stranger (not being a lodger), may be distrained; but animals *ferce natura*, and goods delivered to the tenant by way of trade (as horses in a smithy, garments

at a tailor's), may not be taken. Lodgers' goods are protected against distraint by an Act of 1871; bedding, wearing apparel, and tools or implements of trade to the value of £5 are also protected. Under the Law of Distress Amendment Act, 1888, distress can only be levied by a certified bailiff. A landlord may, by a statute, 11 Geo. II. chap. 19, distrain goods fraudulently carried off the premises; and by the same statute he may, with the assistance of the peace-officer of the parish, break open doors to obtain the goods so removed.—In the American Union, some of the states have abolished distress, as being harsh to the tenant, and unjust in favouring the landlord over other creditors.

In Scotland, the term distress was formerly in use; the right to lay hold of straying cattle and the landlord's right of hypothec are analogous to the English law. See POINDING.

D'Istria, DORA. See GHICA.

Distribution, in Political Economy, refers to the method in which the products of industry are shared among the people concerned. The methods of distribution have varied and do vary in accordance with the state of social development. They depend on legal as well as on economic conditions. They depend mainly on the ideas and institutions which prevail with reference to property in the three requisites of production—viz. land, labour, and capital. In countries where slavery prevailed, the slaveholder, as the owner alike of land, labour, and capital, disposed at his pleasure of the entire product of industry. Under the feudal system, by which the cultivator was attached to the soil and had a fixed interest in it, he was obliged to render to his superiors dues in labour, in kind, and latterly in money, which were fixed by custom or authority. Where the system prevails of cultivators owning the soil, as it does in America, and among the peasant proprietors of the European continent, the owner, inasmuch as he unites in his own person land, labour, and capital, disposes of the entire product, except such portion as may be claimed by the money-lender. In cases where the state owns the land, the cultivator pays a rent or tax to the government, and retains the remainder. The *metayer* system still exists in Italy, the owner advancing the land and stock (in whole or in part), and receiving from the cultivator a fixed share of the produce, generally one-half.

In Great Britain, and to a large extent in other countries with a highly developed industry, land, labour, and capital are supplied, each by a different class of person, and their share in the product is termed respectively rent, wages, and profits (interest, earnings of management, &c.). The respective amounts of these shares are determined by three main factors: (1) the amount produced; (2) the price obtained; (3) the relative bargaining power, collective or individual, of the above three agents. It should be pointed out that under such a system the central function in distribution, as well as in production, rests with the employer. As he originates and controls the productive process, so in the distributive process he settles with landlord and labourer, and markets the product. If the employer operates in whole or in part with borrowed capital, interest on that capital must also be deducted from his share of the produce. All these claims satisfied, the amount of his share will depend on the relative efficiency of his management compared with that of competitive employers. The above process is, however, considerably modified by the influence of law and custom. There is an increasing tendency to revert to judicial rents and wages. Account must also be taken of the growing share in wealth claimed by government through

taxation for public purposes—defence, justice, education, pensions, public health, &c. Some sections of the so-called professional classes are from this source paid for services rendered to the state. But the clerical and teaching professions derive their income more or less from corporate property, while the legal and medical professions obtain their share of the distribution mostly from the services they render to private individuals.

It is now admitted that economists have bestowed excessive attention on production, to the neglect of the problem of distribution. But the reproach has a much wider application than to economists merely, for it may generally be said that while modern communities have enormously increased their productive forces, they have not yet solved the problem of distribution. The enormous inequalities of distribution are a danger felt by all thinking men. It is a question which is more and more challenging the attention of statesmen and economists. An economic system can be satisfactory only when a high standard of production finds its complement in a reasonable and equitable distribution, supplying to the mass of the citizens the means for their due physical, intellectual, and moral development. Merchants, wholesale and retail, are said to effect the distribution of manufactured products, acting as middlemen between the manufacturer and consumer. For special methods of seeking to secure the equitable distribution of profits amongst those who earn them, see CO-OPERATION, PROFIT-SHARING; for other kinds of distribution, see KIN (NEXT OF) and HEIR; also GEOGRAPHICAL DISTRIBUTION.

For an analysis of national income, see *The Division of the Product of Industry*, by A. L. Bowley (1919), *Wealth and Taxable Capacity*, by Sir J. Stamp (1922).

District Councils. See PARISH, LOCAL GOVERNMENT.

District of Columbia, a district of the United States, now coinciding with the federal capital, is bounded on the west by the river Potomac, and on all other sides by Maryland. It originally embraced lands on both sides of the Potomac, the portion east of the river being ceded to the general government by Maryland, and that west of the river (36 sq. miles) by Virginia in 1788-89; the latter section, however, was retroceded to Virginia in 1846, and the present district has an area of 69 sq. miles. The federal city, afterwards called Washington, was laid out from a plan furnished by Major L'Enfant, and the public buildings were erected and completed before December 1800, when the seat of government was removed hither from Philadelphia. In 1814 the British burned the Capitol, White House (the president's residence), and executive buildings, besides much private property, the total damage being estimated at \$2,500,000. The district remained an unorganised territory, under the sole government of congress, up to the year 1871, although it had a county organisation, and Washington and Georgetown held charters for their local government; a congressional committee each session recommended such legislation and appropriations as were deemed needful for it. An Act passed in 1871 organised a territorial government, and provided for a governor to be appointed by the president, and approved by the senate; for a secretary, appointed by the president; and for the election of a delegate to congress, to serve for two years. There was also a legislature, with eleven councilmen appointed by the president, and twenty-two delegates chosen by the people. In 1874-78, however, congress placed the whole control and government of the district in charge of three commissioners, appointed by the president and

approved by the senate. These have full power to make appointments to absolutely all offices in the district; the citizens have nothing to say in relation thereto, nor is a vote given to them either in district or national affairs. Area, 69 sq. m. (land area, 60 sq. m.); pop. (1800) 14,093; (1850) 51,687; (1870) 131,700; (1880) 177,624; (1890) 230,392; (1900) 278,718; (1910) 331,069; (1920) 437,571. See WASHINGTON.

Distrito Federal, a district of the republic of Mexico, including the city of Mexico, almost surrounded by the state of Mexico, but touching Morelos in the south, is directly administered by the federal authorities, with some small measure of local government; area, 678 sq. m.; pop. 1,000,000, mostly in Mexico city.

Dita Bark, the bark of the apocynaceous forest tree *Alstonia scholaris*, found in the Philippines and elsewhere, has tonic and antiperiodic properties, like that of other trees of the genus. It yields an alkaloid ditain or ditarnin, $C_{16}H_{19}NO_2$.

Dital, a key or stop for raising the pitch of a guitar or lute by a semitone.

Ditch, in Agriculture, is a trench usually made along the sides of fields, so that all the drains may be led into it, or along the top of a field to divert surface water. A hedge is often planted along the side, and the two form a better fence for cattle. In cold undrained lands the earth thrown out of the trench forms a mound of dry earth, which is particularly serviceable for the growth of thorn-hedges. Accordingly, in certain districts this is the common mode adopted in planting hedges. Various forms of ditches are made; sometimes a double ditch is adopted, with the hedge between. Since the general use of small and large pipes, however, ditches have in many cases been converted into underground drains, a great saving of land being thus effected, and fields often given a more convenient form. See DRAINAGE.

Ditchling Beacon, a summit of the South Downs (813 feet), 6 miles N. of Brighton, is not the highest point in the range or in the county.

Dithyrambus, originally a surname of Dionysus, of uncertain derivation and meaning, was subsequently applied to a species of lyric poetry cultivated more particularly at Athens, and characterised by loftiness and vehemence of style, which, however, at a later period, degenerated into bombast and extravagance. The Dithyrambus was originally a passionate hymn, sung by one or more revellers to the music of a flute; but Arion is said to have invented for it a regular choral or antistrophic form. He is also spoken of as the inventor of the tragic style, as having introduced among lyrics of a more festive and joyous character, gloomy dithyrambs, representing the sorrows of Dionysus. Lasus of Hermione freed the dithyramb from its antistrophic character; and thenceforward it became more and more mimetic and dramatic. It was out of the mournful dithyrambic songs that the stately and solemn tragedy of the ancient Greeks arose. But few fragments of the dithyrambic poetry survive.

Ditmarsh, DITHMARSCHEN, or DITMARSEN, the western district of Holstein, lying between the Eider and the Elbe, with an area of 550 sq. m., and a pop. of 100,000. It is low-lying and fertile, and has to be defended by dykes from flooding. Originally a part of Saxony, and from 1474 till 1559 practically an independent state between Germany and Denmark, the district still retains many ancient peculiarities. The *Landbuch*, containing the ancient laws, dates from 1348. The *Chronik* was written in the Lower Saxon dialect by Adolff (1559-1629).

Dittany (*Dictamnus*), a genus of Rutaceæ, of which the common species, also called Bastard

Dittany or Fraxinella (*D. albus*), a native of the south of Europe, is an old inmate of our gardens. It is a perennial, with unbranched stem, pinnate leaves, and a fine raceme of white or rose coloured (var. *fraxinella*) flowers. The plant diffuses a powerful fragrance from its numerous oil-glands when in flower, and during dry hot weather exhales such a quantity of volatile oil, that it is said that a slight flash has been obtained by its sudden combustion when a candle is brought near it on a warm summer evening. The root is thick, white, and very bitter, and was formerly in medicinal repute.—Dittany of Crete, used as a febrifuge, is a very different plant (*Organum Dictamnus*), a kind of Marjoram (q.v.).

Diu, a seaport, situated at the eastern extremity of a Portuguese island (7 x 2 miles) of the same name, off the south coast of Kathiawar, 180 miles NW. of Bombay. Once an important city of 50,000 souls, it has sunk in importance till now the whole island has but 20,000 inhabitants, mostly fishermen. Some magnificent buildings still attest its ancient splendour, such as the Jesuit College (1601), now a cathedral. The place has been in possession of the Portuguese ever since 1535, and stood a famous siege in 1545.

Diuretics, medicines having the property of increasing the secretion or excretion of urine, and on this account much employed in dropsies, as well as in a variety of other diseases. The principal diuretics are the salts of potash, especially the nitrate, acetate, and bitartrate (cream of tartar); squill, in powder, vinegar, or syrup; digitalis or foxglove, in powder or infusion; the decoction or infusion of broom-tops (*scoparium*); nitrous ether (in sweet spirit of nitre); caffeine, the active principle of coffee; the alcohols and ethers, with most of the volatile oils, especially that of juniper, as in gin; the berries of the common elder; the tincture of cantharides or Spanish flies; turpentine, &c. The last named (from the alcohols onwards in the above enumeration) are more or less irritating in their effects on the urinary organs, and should not be used without due consideration as to the requirements of the particular case. Cream of tartar and the broom-decoction form one of the safest and best diuretic mixtures which can be employed in domestic use; or cream of tartar may be given alone, either dissolved in hot water and allowed to cool, or in substance along with syrup.

Divan is a Persian word meaning collection, society, council, audience-chamber, as also the kind of cushioned seats or sofas which in reception-rooms in the East are ranged against the wall. Another meaning is a collection of poems—in which special sense of the term Goethe used it for his *West-östlicher Divan*.

Diver, or **LOON** (*Colymbus*), a genus of birds of the family Colymbidae, emphatically oceanic, and confined to northern latitudes. They have a strong, straight, rather compressed, pointed bill, about as long as the head; a short and rounded tail; short wings; thin compressed legs placed very far back, a short hind-toe, and the other digits completely webbed. They fly well, but are particularly expert in diving. They prey upon fish, which they pursue under water, making use of their wings as well as of their legs and webbed feet in their dexterous swimming. On land they can hardly walk, and the name *Loon* is supposed to refer to this incapacity, and to be from the same root with *lame*. They nest on the islands, rocks, or shores of lochs and fiords, but except at breeding-time keep to the water. In winter they sometimes follow the rivers inland. The Great Northern Diver or Loon, also called the Immer

or Ember Goose (*C. glacialis*), is a bird about 2½ feet long, exhibiting no little beauty of plumage; the upper parts black, spotted with white; the head black, with tints of green and blue; the belly white. In winter and in youth it is predominantly brownish-gray and white beneath. It is a winter visitant of the British coasts, even to the farthest south, and is occasionally seen in inland districts; is found in like manner in most parts of Europe, the north of Asia, and North America as far south as Texas, but it breeds chiefly in the more northern regions, as Labrador, Iceland, and Spitsbergen. Its cry is very peculiar and wild, has been likened to the howl of a wolf, and is in some countries superstitiously regarded as ominous of evil. The bird is easily tamed, and becomes very familiar.—The Black-throated Diver (*C. arcticus*) is another northern bird, of similarly wide distribution, but much smaller size, being only about 26 inches in length. It is found round the coasts of Britain, and occasionally breeds in the fresh-water lochs of the north of Scotland. The upper head and neck are ashen-gray, the cheeks and throat black, the general upper surface black with white spots, the under surface white with posterior black spots. In youth and winter it is blackish-brown above, and white beneath.—The Red-throated Diver (*C. septentrionalis*) is also found in all the northern parts of the world, is more common in Britain than either of the other species, and is the bird generally called Loon on the British coasts. In size it scarcely equals the Black-throated Diver. Its back is brownish-gray, the belly white, the throat red. In winter, like the preceding species, this diver is more soberly coloured, and without the red throat. The flesh of all the divers is dark, tough, and unpalatable. The name is sometimes extended to allied genera. See AUK, GREBE, PENGUIN, &c.

Great Northern Diver (*Colymbus glacialis*).

Dives (Lat., 'rich'), the name popularly adopted for the 'rich man' in the parable of the rich man and Lazarus, from the Vulgate translation.

Dividend, the sum falling to be divided among the creditors of a bankrupt from the realised assets, after payment of the expenses. The dividend is reckoned at so much per pound of the claims, and the term is applied both to the whole sum divided and the proportion falling to each creditor (see BANKRUPTCY). The profits of a bank, railway, or other joint-stock company, distributed annually or half-yearly among the shareholders, are also called dividends; and the same term is used to denote the interest payable on the public funds, and sometimes on other loans and debentures.

Dividing Engine. See GRADUATION.

Dividi'vi, or **LIBIDIBI**, the curled pods of *Cassalpinia coriaria* (see CASSALPINIA), a West

Indian and South American leguminous tree, are of remarkable astringency, and are imported especially for use in tanning.

Divination (Lat. *divinatio*; Gr. *manteia*, *mantikē technē*), the act of obtaining the knowledge of unknown or future things by supernatural revelation, or more strictly, the knowledge of the divine thought manifested to the human soul by objective or subjective signs, and apprehended by means outside the range of the rational. It postulates a belief in a divine providence, and the possibility of reciprocal relations between man and God considered as being able to contribute to man's happiness. Its essential characteristic is thus a belief that the divine thought may be comprehended by the human understanding in a knowledge of a special nature, more or less direct, more or less complete, but always through supernatural means, with or without the concurrent agency of the reason. Thus its domain includes all that the human mind can apprehend by its own powers; in the first place, the future, in so far as it escapes rational foresight; in the second place, the past and the present, in so far as they are inaccessible to ordinary investigation. This supernatural knowledge, says M. Bouché-Leclercq, has been oftener applied to the investigation of the past or of the present than to that of the future. Most of the ancient prodigies were considered as having their causes in the past; the result of their interpretation was always to make known the present will of the gods, and through that, but indirectly, the secrets of the future. And in the future even, considered as capable of being modified, divination oftener teaches that which should happen in accordance with the actual plan of providence, than reveals that which actually will happen. It is closely connected with magic, which may here be defined summarily as the art of voluntarily producing effects contrary to the laws of nature, by a mastery over obscure supernatural forces. Many of its methods consist in the interpretation of the marvellous effects produced at first by magical receipts, and there is an element of magic in every practice or rite destined to prepare or to produce an act of divination. While magic is the consequence of the active knowledge which permits the human will to make use of supernatural influences, the specially prophetic faculty—the particular function of the diviner—on the other hand, is the result of the contemplative knowledge which places the divine thought within the scope of the human intelligence. The former is an enlargement of the activity and of the human initiative at the expense of the divine freedom; the latter is like an increase of visual power added to the understanding.

Otherwise a broad distinction may be made between *artificial* divination by haruspication, astrology, lots, the interpretation of prodigies, lighting, augury, and the like; and *natural* divination, by dreams and prophetic oracles, considered as the direct revelation of the divine will, or an inward intuition flashed with irresistible conviction upon the human soul. The last subjective divination follows from that conception of the prophetic function which had its place in the philosophical system of Plato. It proceeds by a state of psychic exaltation or prophetic ecstasy, which suspends the intellectual energies of the human agent in a kind of sympathetic passivity suitable for the transmission of the divine thought. The conditions most favourable for receiving the divine impressions have beforehand been induced by the weakening or the destruction of the individuality of the medium through certain morbid physiological conditions, as ecstatic enthusiasm, deep sleep, sickness, or the approach of death—the last, a notion that lingers long in the heart of our modern

civilisation. The scientific spirit of Aristotle rejects external divination and accepts subjective prophecy, but reduces it to nothing more than the natural exercise of a special faculty. 'It is neither easy,' he says, 'to despise such things, nor yet to believe them.' The Stoical school maintained divination because the gods were too beneficent to have denied to men a gift so good, but they identified providence with necessity or the inevitable connection of causes and consequences, and thus involved divination in an illogical confusion between fatalism and free-will, the only reason for its existence that remained being its utility. The usual attempt at an explanation was that divination and the consecutive resolution of man had been foreseen with the rest by providence, and that thus its end was active co-operation in the realisation of the divine plan. The Epicureans made divination impossible by leaving it neither object nor agent, for their gods exercised no providence over men. The sceptical Lucian imitates Aristophanes in his amusing burlesques on the difficulty which Apollo feels in composing his official hexameters. The brilliant Carneades left divination in its fatal dilemma between necessity and free-will, and Cicero follows with a halting conservatism, unable entirely to surrender his wishes to a conviction that his logic demands. Pliny the naturalist and Suetonius feel all the embarrassments of the old dilemma, and their attitude to divination may to some extent be explained by classifying them as superstitious rationalists. Plutarch, an eclectic Platonist, enumerates with marked particularity all the prodigies and miracles that had happened to his heroes, and seems to have believed in an innate human faculty for divination, a state of receptivity through which the soul becomes the instrument of God, just as the body is the instrument of the soul. With the spiritual revival that marked the rise of Neoplatonism, we find divination again established and based on cosmic sympathy. The Egyptian ascetic Plotinus accepted inward revelation, and directly ascribed all the phenomena of divination to the agency of the gods and other spiritual forces. Porphyry had an intensely vivid sense of the spiritual in nature, and regarded the supernatural and its external expression almost as the least extraordinary of all her secrets. The divine communicates itself to the human through inward illumination in specially gifted souls, and to others less highly endowed through dreams, chance presages, and voices.

The early Christian controversialists accepted the supernatural inspiration of the Pagan oracles, but explained that it came not from God, like that of the Hebrew prophets and the saints, but from the devil. It was easy for them to demonstrate the fallacy and errors of the ancient oracles, but they were hardly logical in, at the same time, accepting such of these as could be interpreted as foretelling the coming of Christ or some of the peculiar dogmas of Christian theology. It was St Augustine who finally formulated the orthodox opinion of western Christianity on the subject in a special treatise, *De Divinatione Dæmonum*. He limits greatly the part ascribed to conscious fraud in the function of the diviner, as he found the whole mystery sufficiently explained by the intervention of the bad angels, which existed in such countless numbers. The devils imitated as far as possible the divine methods, and hence we have false dreams, visions, and prophetic inspirations resembling in everything save their origin those so often vouchsafed to the saints. Thus early Christianity agreed perfectly with Paganism upon the facts of divination, simply substituting the wicked angel for the good genius and the gods of a polytheistic religion. It merely eliminated the external rites, as infected with magic,

substituting for these prayer, and preserved everything that came spontaneously from God, as dreams, visions, and prophetic inspirations. Perhaps the feelings that lay at the heart of the faith in the ancient divination helped unconsciously to prepare the human mind for the Christian belief in providence, in the efficacy of prayer, and in a special revelation of God to man.

Many of the most ancient forms of artificial divination have survived to our own day, even in the heart of our vaunted modern civilisation. The sense of the efficacy of these methods undoubtedly depends on the association of ideas in supposed analogies, and in symbolism. The Samoan rain-doctors wet a stone when they want rain, and dry it at the fire when they want dry weather; and sorcerers all the world over bring harm upon their victim by wishing it strongly, or by prophesying that it will happen, as well as by symbolically representing it in some simple act, as by torturing a wax-model or the like. There is an elemental confusion between the subjective and the objective connection which the primitive mind is unable to distinguish. It cannot resist the conviction that association in thought involves similar connection in reality. The analogies are not consciously arbitrary, but admit fairly of ratiocination if we can get into the proper mental attitude to commence the chain. Rousseau's conviction of his salvation or damnation from his hitting or missing a tree with a stone is based upon a mental process natural enough to the primitive mind. Added to this is the belief in the direct agency of supernatural powers which influence the casting of lots or the tossing of a coin, now a mere mechanical appeal to blind chance, but once a solemn attempt to educe the divine will. Early grave ideas of supernatural interference with games of chance linger long in folklore, and we still turn our chair to change our luck at dice or cards, and attach absurd importance to certain numbers for lottery-tickets. The Moravian Brethren even chose their wives by sortilege or casting lots with prayer, just as the Hebrew patriarchs did at grave or doubtful junctures three thousand years ago. The ancient Greek *kottabos*, by which fortune in love was discovered by the particular splash made by wine thrown out of a cup into a metal basin; the *astragali*, or knuckle-bones of the Romans, used for divination and as dice; the Polynesian divination by spinning the *niu* or coconut to see if a sick person will recover; and the playing-cards by means of which Gypsies still read fortunes at English fairs (*cartomancy*), are enough to show the great variety in range of methods of divining. Many of these have been gravely formulated and systematised into pseudosciences. Thus astrology was not only one of the most serious studies of the ancient Chaldeans, but was still more than respectable in the time of Newton; augury by the sight and cries of birds alone gave employment to a whole college of officials in ancient Rome; and the ordeal by fire or battle had the most solemn sanction of the medieval Christian church.

Many of the notions lingering in folklore about the hearing of certain birds on the right or the left hand, or the meaning attached to first meeting certain animals or people and the like, may be understood by symbolism; but many more are now at least completely inexplicable and hopelessly confusing. Dreams to animistic thinkers are directly due to spiritual intercourse, and their symbolical interpretation (*oneiromancy*), either as taken directly or by the equally valid method of contraries, has been practised from the days of Joseph until now, and has given rise to a rich crop of folklore superstitions everywhere. Divination by the appearance of entrails, or *haruspication*, was much

respected by the ancient Romans, and is still practised by the Malays and Polynesians. Somewhat similar to it is *scapulomancy*, the method of divining by the cracks and lines made in a shoulder-blade placed in the fire. Palmistry, or *cheiromancy*, has still its thousands of votaries and its own literature, and is warmly defended by those who fail to see how childish is the sham symbolism, and how entirely arbitrary are all the analogies on which it is based. Other methods of divining again may depend on the more or less conscious action of the agent. Such is the *planchette*, by means of which answers in writing are given; but the most famous form in this kind is the divining-rod, with its supposed power of indicating a hidden spring of water, a vein of ore, or a buried treasure (*rhabdomancy*). For these, see AUTOMATIC WRITING, PLANCHETTE, and DIVINING-ROD. Of the same nature are the ancient *coscinomancy*, with a hanging sieve and shears, and the ordeal of the key, both highly useful where a culprit was apt to betray himself by his fears. Other of the thousand forms of divination are *bibliomancy*, by opening at random the Old or New Testament, or such popular books as the works of Homer or Virgil; *crystallomancy*, by looking into a crystal or beryl to see the future represented directly in pictures, or symbolically by figures capable of being interpreted; *geomancy*, by the observation of points or lines on the earth, or on paper; *pyromancy*, by the behaviour of fire; and *botanomancy*, from the chance combinations made by the wind upon leaves of trees on which words and questions had been written. Of profound significance also are the barking of dogs, the fall to the right or left hand of stones or sticks flung upwards, the behaviour of a ring hung over a cup at the approach of particular persons, the spots on the finger-nails, the physiognomy of the persons met by chance at critical periods, the blowing off the seeds of the dandelion, or the pulling off the petals of the daisy with certain time-honoured formulas repeated the while. Countless omens are derived by means of hemp sown at midsummer, by nuts burned before a fire, from certain appearances of green ivy leaves, willow-wands, and the like; while those who are observant of the proper rites may ward off ill-luck, and force the future to their convenience, with the sign of the cross, and the use of the horseshoe, silver, or the holly. The future is often foretold also by apparitions, and these are not infrequently, as in the classical case of the witch of Endor, capable of being called forth for the purpose of prophesying by powerful sorcerers.

Divination is founded on faith, but has often also been helped by fraud. It is a sincere although fallacious philosophy, and finds its strongest support in the fancied proofs of its truth that strike the minds of a primitive people, who forget or overlook the misses in their eagerness to verify the hits. The persistent tendency to believe what one wishes to believe, and the inherent human craving for mysteries and wonders, account for any belief. 'The human understanding,' says Bacon, 'when any proposition has been once laid down (either from general admission and belief, or from the pleasure it affords), forces everything else to add fresh support and confirmation; and although most cogent and abundant instances may exist to the contrary, yet either does not observe or despises them, or gets rid of and rejects them by some distinction, with violent and injurious prejudice, rather than sacrifice the authority of its first conclusions.'

See the articles APPARITION, ASTROLOGY, AUGURIES, CHARM, DEMONOLOGY, DIVINING-ROD, DREAM, OMENS, ORACLES, ORDEAL, MAGIC, MYSTICISM, PALMISTRY, and SORTES VIRGILLIANÆ; also Bouché-Leclercq's *Histoire de la Divination dans l'Antiquité* (4 vols. 1879-82); Halliday's *Greek Divination* (1913).

Divine Right, a term applied to describe the source of the power claimed for the monarch, by the royalist party, in the great controversies between the monarchical and parliamentary or commonwealth parties in England in the 17th century. The monarch was held to be the immediate representative of the Deity, to whom alone he was responsible for all his actions—a principle which relieved him from all human responsibility, and gave him an absolute claim to the obedience of his subjects. Two of the confessions of Henry VIII.'s reign—the *Institution* and *Necessary Doctrine*—both insist on the duty of passive obedience as a corollary of the fifth commandment; and Cranmer so altered the coronation oath at the accession of Edward VI., as to make the king's hereditary right wholly independent of election or the will of the people. But the doctrine became full fledged only after the quiet transfer of the crown from the Tudor to the Stewart dynasty showed that the hereditary principle was firmly established; and James I. constantly harped on the necessity of this great principle. The chief writers on the side of divine right were Salmasius and Sir Robert Filmer; on the other, Milton, Algernon Sidney, and Harrington. The controversy died a natural death after the accession of the Hanoverian dynasty. The miraculous power claimed by English sovereigns of curing the 'king's evil' (see SCROFULA) by the royal touch, was a consequence of their divine right. See J. N. Figgis, *Divine Right* (2d ed. 1914).

Diving. The 'treasures of the deep' have at all times been the subject of much visionary exaggeration, and the accounts of the exploits of divers equally extravagant. Thus, it is sometimes affirmed that the pearl-divers of the East acquire by practice the power of remaining under water from 15 to 20 minutes, or even two hours. It need scarcely be said that these accounts are absurd, no such endurance being possible. The more skilful divers may remain under water for 2 or even 3 minutes; and 4 minutes 29½ seconds is claimed to have been attained in a glass tank (see PEARL). Most divers suffer severely from the continual efforts in holding the breath; blood-shot eyes and spitting of blood are common among them. It is noteworthy that if one about to dive breathes hard for a short time, he is then able to hold his breath much longer under water (see SWIMMING). The rude mode of diving is now but little used except for pearl and sponge fishing. Even for these purposes the diving apparatus is now largely used, the diver thus collecting, it is computed, as much as twenty naked divers under the old primitive regime, and being able to remain from two to four hours under water. In the Mediterranean sponge-fisheries, hundreds of sets of diving apparatus have long been in use, and the dress has been introduced into the fisheries at the Bahamas, Bermuda, Australia, &c.

DIVING-BELL.—For all such purposes as subaqueous works upon the foundations of piers, bridges, &c., or the exploration and raising of sunken vessels, the efforts of the unaided diver would be almost valueless, and, accordingly, various contrivances for supplying air to the diver have been made. Roger Bacon (1240) is said, on most doubtful authority, to have invented a machine for working under water. Taisnier's description of the *cacabus aquaticus*, or aquatic kettle, used by two Greeks in Spain, at Toledo in 1538, in the presence of the Emperor Charles V. and a multitude of spectators, is, one of the earliest reliable accounts of a diving-bell. From his description, this must have been similar in principle and construction to the modern diving-bell, but of clumsy dimensions, and wanting in efficient means of renewing the supply of air. In

1620 Lord Bacon in his *Novum Organum* describes the crude method in vogue in his day, in which no means of replenishing the air were employed. Towards the close of the 17th century, many attempts were made, and much capital sunk in submarine exploration, but the primitive nature of the apparatus employed rendered the various enterprises undertaken abortive. Dr Halley's diving-bell, about 1720, was a wooden chamber of about 60 feet internal capacity, open at the bottom, where it was loaded with lead, to keep it perpendicular in its descent. Strong pieces of glass were set in the upper part, to admit light. Casks filled with air, and loaded with lead, were let down with the bung-hole downwards; and from these a supply of air was drawn by means of a hose. John Lethbridge, about the same time, constructed a conical bell, into which he forced compressed air by means of bellows, enabling him to remain over half an hour beneath the surface. In 1754 Dr Richard Pococke saw a diving-bell used at the Needles to raise what they could of the wreck of a man-of-war. 'They are let down in a machine made of leather, strengthened at the knees and shoulders, and, if I mistake not, on the head, with brass. There are two leathern tubes to it—one for the air to go down and to speak by, the other to pump out the air. They stay down five minutes' (*Travels through England*, Camden Soc. 1889). In 1779 Smeaton employed an oblong box supplied with air by means of a pump on the surface, for repairing the bridge at Hexham, in Northumberland.

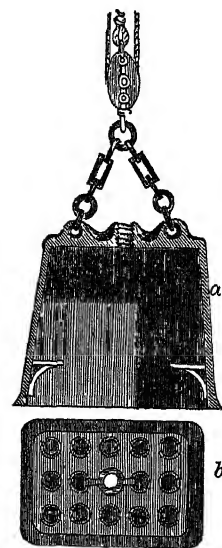

The form of diving-bell now in use was first constructed by Smeaton for work at Ramsgate, in 1788. It was of cast-iron, and weighed 50 cwt., its height 4½ feet, length the same, and width 3 feet. It sunk by its own weight, and was lighted by stout pieces of bull's-eye glass, firmly cemented in brass rings near the top. The next improvement of importance was that due to Rennie, who designed in 1813, for the works of Ramsgate Harbour, a diving-bell of cast-iron, 6 feet high, 4 feet 6 inches wide, and 6 feet long. Six bull's-eyes of glass in the top admitted light. Air was admitted through the top by a valve, and was supplied by an air-pump through a 2½-inch hose. The interior of the bell was fitted with seats, chains for attaching stones, &c., and a rail for carrying tools. The bell, which weighed about 5 tons, was suspended by stout chains to a crab fixed to a truck travelling on an overhead gantry, and was successfully employed in various undertakings carried out by its designer. Access is gained to some large diving-bells by means of a wrought-iron shaft and Air-lock (q.v.), whereby the necessity of raising the bell is obviated. This apparatus has been both efficient and economical in working.

The air-chambers of the caissons used for founding the piers of bridges are nothing more than huge diving-bells, only they remain in position when sunk to the requisite depth, and are filled up solid with masonry (see CAISSON). At the St Louis Bridge across the Mississippi the maximum depth attained was 110½ feet, and the greatest pressure 51 lb., a pressure which proved fatal in a few instances to the workmen. The air-chambers of the caissons of the Forth Bridge were 70 feet in diameter, and 7 feet high. The work of excavation was carried on by electric light, and presented a singularly novel and weird spectacle. The maximum pressure was about 33 lb. per sq. inch above the atmosphere. The altered conditions of existence under a pressure of three atmospheres presents many points of interest. The voice sounds unnatural, and as if proceeding from another person; whistling is impossible. Effervescing drinks open flat, the pressure outside being

equal to that accumulated in them. lassitude is generally experienced through the air-lock on entering, and the gradual admission of pressure, is at times, and more especially to novices, accompanied by severe pains in the ears; but with due care, and the observance of the prescribed simple expedients, these pass away. Under increased air-pressure the blood dissolves a considerable quantity of atmospheric nitrogen, which in the diving-bell remains dissolved just as does the gas in aerated waters. When the pressure is released it is liberated in bubbles in the blood-vessels, and produces the symptoms of 'caisson-disease.'

The principle of the diving-bell will be easily understood by floating a piece of lighted candle or a wax match on a cork, and then covering it with an inverted tumbler, and pressing it downwards; the candle will descend below the level of the surrounding water, and continue burning for a short time, although the tumbler be entirely immersed. The reason is obvious enough: the air in the tumbler having no vent remains in it, and prevents the water from occupying its place, so that the cork and candle, though apparently under water, are still floating, and surrounded by the air in the tumbler; the candle continues burning until the oxygen of the air is exhausted, and then it goes out, as would the life of a man under similar circumstances. If vessels full of air, like the barrels of Dr Halley, were submerged, and their contents poured into the tumbler, the light might be maintained; but this could be better done if a tube passed through the tumbler, and air were pumped from above through the tube into the tumbler.

The modern diving-bell, which is made of cast-iron like Smeaton's, is supplied with air in this manner. It must be remembered that air is compressible, and diminishes in bulk in proportion to the pressure, so that at a depth of about 33 feet in water, it would occupy half the space it filled at the surface; if the inverted tumbler were carried to this depth, it would be half-filled with water. A considerable quantity of air has therefore to be pumped into the diving-bell, merely

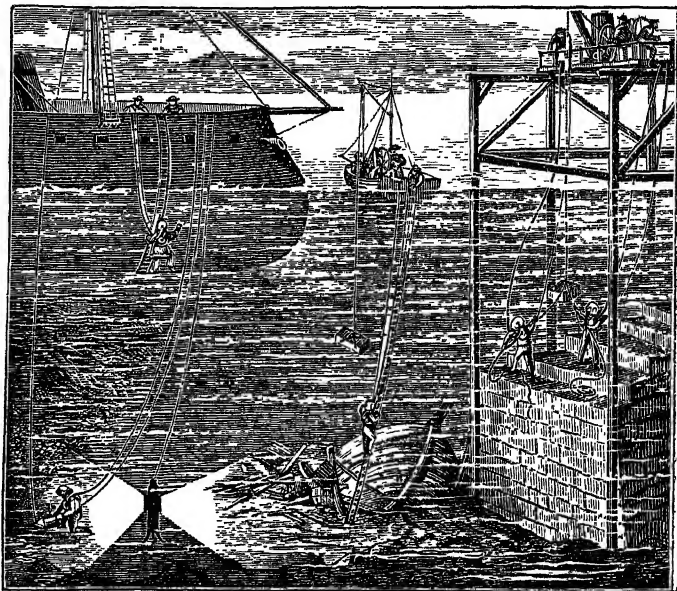

Diving-bell:

a, section showing inside;
b, top.

to keep it full as it descends; the air thus compressed exerts a corresponding pressure, and would rush up with great force if the tube were open and free. This is prevented by a valve opening downwards only. When the diving-bell has reached its full depth, the pumping is continued to supply air for respiration; and the redundant air overflows, or rather

A feeling of
on return to
The passage

underflows, by the open mouth, and ascends to the surface in great bubbles. The diving-bell is provided with a platform or seat for the workmen, and

Divers at Work.

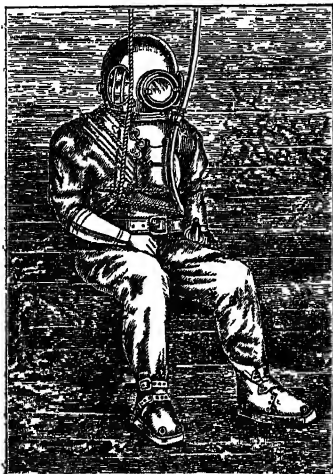

suspended from a suitable crane or beams projecting from a barge or pier; men above are stationed to work the pumps, and attend to the signals of the bellman. These signals can be made by striking the sides of the iron diving-bell with a hammer, and as sound is freely communicated through water, they are easily heard above. One blow signifies 'more air'; two blows, 'stand fast'; three, 'heave up'; four, 'lower down'; five, 'to eastward'; six, 'to westward'; &c. These, of course, may be modified as agreed upon. Messages may also be sent up written on a label attached to a cord. The telephone is now used.

DIVING-DRESS.—In Schott's *Technica Curiosa*, published in 1664, is described a *lorica aquatica*, or aquatic armour, which consisted of a leathern dress and a helmet to protect the diver from the water. In 1721 Halley describes a contrivance of his own of nearly the same kind; its object was to enable the diver to go out from the bell and walk about. He was to be provided with a waterproof dress, and a small diving-bell, with glass front, as a helmet over his head, which was to be supplied with air by means of a tube from the diving-bell. Kleingert, of Breslau, in 1798 devised a diving-dress, consisting of strong tin-plate armour of cylindrical form encasing the diver's head and body; the lower portion of his person being clad in stout leathern costume. A pipe conveyed air to the diver, whilst a second pipe returned the air when vitiated to the surface. This apparatus was available only for depths up to 20 feet.

The open helmet diving-dress was invented in 1829 by Augustus Siebe, and marked considerable advance on previous attempts. This dress consisted of a copper helmet with breastplate attached, a canvas jacket being fastened to the latter. The lower part of the jacket was left open (hence the name), and the air escaped by this outlet, hence the water was only a few inches below the diver's mouth, and he had to maintain a vertical position. Leather boots loaded with lead were also worn.

In 1839 Siebe obviated the dangers attendant on the open dress by perfecting his close dress—a

waterproof costume covering the whole body, save the head and hands, of strong tanned twill and rubber, with vulcanised rubber collars and cuffs. The helmet is made of tinned copper with three circular glasses in front; sometimes guards are added to protect them. The front eye-piece is made to unscrew and enable the diver to receive or give instructions without removing the helmet. One or more outlet valves are placed at the back or side of the helmet to allow the vitiated air to escape.

Diving-dress.

These valves only open outwards by working against a spiral spring, so that no water can enter. The inlet valve is at the back of the helmet, and the air on entry is directed by three channels running along the top of the helmet to points above the eye-pieces, enabling the diver always to inhale fresh air, whilst condensation on the glasses is avoided. The helmet is fixed to the breastplate below by a segmental screw-bayonet joint, securing attachment by one-eighth of a turn. In some dresses the escape valve is regulated at will by the diver, and enables him to vary the pressure, and even to float himself by closing the valve and inflating his dress, but except in the hands of a skilled man this may prove a source of danger. The junction between the waterproof dress and the breastplate is made watertight by means of studs, brass plates, and wing-nuts. The diver carries back and front weights, each about 40 lb. The boots, made of stout leather with leaden soles, weigh about 16 lb. each. The helmet weighs about 40 lb. A life or signal line enables the diver to communicate with those above; or the diver may speak to his attendant, or to other divers, by a telephone fitted to his helmet. The air-pipe is made of vulcanised india-rubber with galvanised iron wire imbedded.

In the diving-dress invented by Fleuss, and patented by him in 1880, the diver is independent of supplies of air from above. A strong copper cylinder fastened to the back of the diver carries a supply of compressed oxygen, regulated at will by a jamb screw-valve. The carbonic acid exhaled by the diver is absorbed by caustic soda in a receptacle fixed above the copper cylinder, whilst the nitrogen is breathed over and over again. In this dress, which weighs about 26 lb., and can be adjusted in a few seconds, a man may remain below the surface for several hours without harm. In clear water and at moderate depths no light is required, but where illumination is necessary, an improved oil-lamp, invented by Siebe, supplied with air by a small force-pump, has been employed. Both arc and incandescent electric lights are now used for this purpose with most satisfactory results. Communication is made by means of the telephone, a slate, or ordinary signal line. Siebe states the greatest depth to which a man had ever descended to be 204 feet, equivalent to a pressure of $88\frac{1}{2}$ lb. per sq. inch; but by means of later methods used by

the British Admiralty, two officers have done practical work in safety at 210 feet. Three United States divers have remained 5 to 27 minutes at the bottom at 275 feet. With still more recent apparatus, German divers have reached a depth of about 500 feet. Slight men of muscular build, with good circulation, sound hearts, steady nerves, and temperate habits, make the best divers.

Divining-rod, often called the *Virgula Divina*, the *Baculus Divinatorius*, the Caduceus or wand of Mercury, the Rod of Aaron, is a forked branch, usually of hazel, and sometimes of iron, or even of brass and copper, by means of which minerals and water are said to be discovered beneath the surface of the earth. The rod, when suspended by the two prongs, sometimes between the balls of the thumbs, indicates by a decided inclination the spot under which the concealed mine or spring is situated. It has often been used also to discover the authors of a crime, as by the famous Jacques Aymar in a case of murder and robbery at Lyons in 1692. Many men, even of scientific knowledge, have been believers in the occult power ascribed to this magic wand. Agricola, Sperlingius, and Kirchmayer all believed in its supernatural influence. Bayle, under the word *Abaris*, in his Dictionary, gives some ingenious arguments both for and against the divining-rod. It seems to be still believed in, not only by Cornish miners, but by some English civic officials, men of science, and other responsible persons, even in the 20th century.

Most scientific authorities regard this alleged power of the divining-rod as due to a more or less unconscious delusion, the phenomena merely being the effect of a strong impression on the mind acting through nerves and muscles.

See Chevreul's *De la Baquette divinatoire* (1854), Lang's *Custom and Myth* (1884), and the testing experiments near Vincennes in March 1913, and at Guildford in April 1913. But see also Barrett in *Proc. Soc. Psychical Research* (1897, 1900).

Divisibility is that property in virtue of which the whole may be broken up into parts. This process of division may be conceived to be carried on indefinitely so far as space is concerned. But the question of infinite divisibility as applied to matter at once raises the further question of the Atom (q.v.), and the Electron (q.v.). See also MATTER. A thickly gilt silver rod has been drawn out into a fine wire still covered with a continuous coating of gold the thickness of which must have been about $\frac{1}{1000000}$ th of an inch. A small particle of common salt placed in a flame will colour it for some hours; and one grain of musk can scent, by its slow evaporation, the air of a room for years.

Divisibility, in the Theory of Numbers, is that property of any number whereby it may be divided by another without remainder. To find the condition of divisibility of one number, N , by another, D . Let $N = b_0 + b_1 r + b_2 r^2 + \dots + b_{m-1} r^{m-1} + b_m r^m$, where $b_0, b_1, \&c.$ are coefficients, and r is the *radix* of the notational scale (see SCALES OF NOTATION). Introducing D and $-D$ along with r , we may write: $N = b_0 + b_1 (D + r - D) + b_2 (D + r - D)^2 + \dots + b_m (D + r - D)^m$. Expanding the terms on the right-hand side of this equation, it will appear that $\frac{N}{D}$ will be an integer if

$b_0 + b_1 (r - D + \dots + b_m (r - D)^m)$ be divisible by D . For example, if $r = 10$ (i.e. if the number be given in the denary or ordinary scale), and $D = 9$, and therefore $r - D = 1$, any number will be divisible by 9 if the sum of its coefficients $b_0, b_1, \&c.$ be so—i.e. if the sum of its digits be divisible by 9. Further rules found in this manner are fully given in Mackay's *Arithmetical Exercises*.

Division, of an army, is the unit which contains all branches of the service, except the flying corps and siege artillery. The table shows the war establishment of a British division in 1914:

Detail.	Officers	Other Ranks	Horses	Guns	Vehicles *
Headquarters	15	67	54	—	7
3 Infantry Brigades . . .	372	11,793	741	24	201
Artillery Headquarters . .	4	18	20	—	—
3 Field-Artillery Brigades	69	2,316	2,544	54	225
1 Howitzer Brigade	22	733	697	18	62
1 Heavy Battery	6	192	144	4	18
Ammunition Column	15	553	709	—	104
2 Companies Engineers	15	432	160	—	38
1 Signal Company	5	157	80	—	12
1 Cavalry Squadron	6	153	167	—	3
Supply Train	26	402	378	—	146
3 Ambulances	30	672	198	—	69
Total	585	17,438	5,502	100	385
At Base	18	1,732	16	—	—

* Exclusive of gun-carriages and bicycles. Of the latter there are 275, and 9 motor-cycles.

The infantry 'guns' are machine-guns. Tent supply is not provided for in the normal establishment. Ammunition is provided by a series of reserves—for infantry companies on pack-cobs, for batteries in 6-horse wagons, for battalions in 2-horse carts, for infantry and artillery brigades in 4-horse and 6-horse wagons, for the whole division in a horsed ammunition column, which is kept filled by an ammunition park of motor-lorries working from the advanced base. Three days' rations for men, and two days' forage for horses, are carried, chiefly by the supply train (horsed), which is kept filled by a motor supply column.

In large foreign armies, Japan excepted, two divisions, similar to, but weaker than, the British, constitute an Army Corps (q.v.). A cavalry division is composed of a number of Brigades (q.v.), with horse-artillery batteries, squadron of engineers, ambulances, and a signal squadron.

Naval Division.—For convenience of command and manœuvring a fleet is divided into two, three, or more divisions, and each division into two sub-divisions. Each division is commanded by a flag-officer.

Division of Labour is based on the principle that industry can be best carried on when each man has a special work to do. Constant practice in doing the same thing leads to a perfection which could not otherwise be attained. The classical illustration of it in the history of political economy is that of pin-making as given by Adam Smith: 'One man draws out the wire, another straightens it, a third cuts it, a fourth points it, a fifth grinds it at the top for receiving the head; to make the head requires two or three distinct operations; to put it on is a peculiar business; to whiten the pin is another; it is even a trade by itself to put them into a paper; and the important business of making a pin is in this manner divided into above eighteen distinct operations, which in some manufactories are all performed by distinct hands.' In this way ten men could make about 48,000 pins in a day, whereas, if they worked separately and independently, they certainly could not each of them have made twenty, perhaps not one pin in a day. Adam Smith offers the following reasons why the division of labour secures greater efficiency: 'First, the increase of dexterity in every particular workman; secondly, the saving of the time which is commonly lost in passing from one species of work to another;

and lastly, the invention of a great number of machines which facilitate and abridge labour, and enable one man to do the work of many.' Economists believe, however, that Smith has laid too great stress on both the second and third of the above reasons.

Though the name of Adam Smith has been so closely associated with the principle of the division of labour, the importance of it had been recognised before, notably by Plato in his *Republic*, and by Adam Ferguson in his *History of Civil Society*. And it is hardly necessary to say that the invention of labour-saving machinery has rendered the example of the principle which he drew from pin-making almost entirely obsolete as an illustration of the existing methods of industry. (A good example of division of labour is given under CUTLERY: an ordinary three-bladed pocket-knife goes through more than a hundred processes; similarly with needles. Pins, which were made in thousands through the co-operation of human hands, are now turned out in millions by the aid of machinery. In modern industry very little is due to the direct operation of the human hand; almost everything is done by a machine. The development of steam and electricity as the motive powers, both of production and exchange, has along with the parallel development of machinery completely revolutionised the conditions of industry, necessitating a division of labour on a far wider basis than that contemplated by Adam Smith. At the present day it is not a mere question of personal adaptation, but of local, national, and international fitness and specialisation for carrying on different forms of industry. Differences of climate and of other natural conditions, as well as differences of industrial development, impose upon nations a most comprehensive division of labour.

This division of labour, it must be obvious, has as its necessary complement an elaborate combination or organisation of labour. In every large industrial undertaking, whether it be a factory, railway company, or any other, the highest efficiency can be attained only when, every man having his proper work to do, each man's work effectually contributes towards the general result. It is only through the wise selection of the fittest persons for each class of work, and their special adaptation to it, that such an organisation can be maintained. Thus the division of labour is only a factor in the wider problem of the organisation of labour, necessary to the success of every great industrial undertaking. See LABOUR.

But while the division of labour is necessary towards an efficient industry, economists recognise that it has many disadvantages. It is attended with a monotony of occupation, which is not favourable to the development of the general intelligence and capacity of the workmen. Each man can perform his own narrow function, and beyond that his skill does not go. The monotony itself is most painful, especially under the long hours of work which prevail in so many countries. But the worst feature of all is that through the changes which so frequently occur in the industrial world, owing to the introduction of new machinery and other causes, the class of work to which the men have been trained may be entirely superseded. The most striking instances of this in the history of English industry was hand-loom weaving, rendered obsolete by the introduction of the power-loom. Workmen thus trained and specialised have a great difficulty in finding, and in adapting themselves to, any other form of occupation.

Division of Labour, a conception borrowed from Economics and introduced into Biology by Milne-Edwards, to describe the difference of function exhibited by the individual members of an

animal colony, or by the different organs, tissues, and cells of a single organism. The figure of a hydroid colony, *Hydractinia*, shows how members, primarily and fundamentally the same in structure, become set apart as nutritive, reproductive, sensitive, and protective. The same division of labour or predominance of special functions in different individuals is beautifully illustrated in the Siphonophora—such as the Portuguese Man-of-war (q.v.).

Hydractinia ecunata
(after Allman):

a, nutritive individuals; b, reproductive; c, sensitive; and d, sensitive individuals.

At a much higher level, vivid illustrations of the same fact may be found among the social Ants (q.v.) and Bees (q.v.). But division of labour in some degree is essential to every organism. Even in a single unit mass or cell, it is hardly possible for all the parts to be entirely in the same external and internal conditions; certain portions become more contractile, others more sensitive, others more nutritive, and so on. In a ball of cells, such as *Volvox*, the inequality in the conditions becomes more marked; the inside cells are not in the same state as their outside neighbours; they thus become seats of different vital processes, and distribution of function or division of labour is the result. The same process may be traced in the gradual evolution of tissues and organs, as also in the development of special 'persons' with limited and preponderant functions in animal colonies. When the predominance of some function has been established, it brings with it difference of structure. This differentiation or, when it concerns a colony, polymorphism is the structural side of the physiological fact of the division of labour. See COLONIAL ANIMALS, DIMORPHISM, HYDROZOA, &c.

Divorce is the disruption of the legal tie between husband and wife. The desire to obtain a release from the matrimonial bond has existed under all systems of law or custom. In early times, such release was often permitted on very easy conditions. The Romans of the late republic and the empire permitted divorce at the will of either spouse; but a husband divorcing without cause forfeited the wife's dowry. The Emperor Constantine was the first to prohibit divorce at the mere will of the parties; after some fluctuations in the state of the law, the grounds which would justify husband and wife respectively in divorcing were settled by Justinian. These changes in the law were partly due to the introduction of Christianity.

The Jewish law of divorce is contained in Deut. xxiv. 1-4. The Christian view of marriage is declared in Matt. xix. 9; Mark, x. 9-12; Luke, xvi. 18; and 1 Cor. vii. Marriage was held by the early Christians to be a sacred tie, not to be dissolved except for unfaithfulness. By the canon law it was regarded as a sacrament, and the tie could not be broken, even in the case of adultery, except by a papal dispensation. In cases of misconduct, a separation *a mens et thoro* might be decreed; or if the marriage had not been regularly contracted, it might be declared null *ab initio*. Suits for

separation, or for a declaration of nullity, belonged to the ecclesiastical courts. These rules of the canon law were not uniformly adopted by European states; but in 1562 the Council of Trent established in Catholic countries the rule that marriage should be deemed indissoluble, even after adultery.

Many of the Reformers disputed the Catholic view of marriage. For reasons stated by Milton in his tract on the subject, they permitted a certain liberty of divorce. But in England the old rule held its ground till 1857-58; marriage could only be dissolved by a special act of parliament. A husband petitioning for such an act was required first to sue for a separation, and to bring an action for damages against the seducer of his wife. Divorce, therefore, was possible only for the rich.

By an Act of 1857 the jurisdiction in divorce and matrimonial causes was transferred to a new civil court, which since 1873 has formed part of the High Court of Justice, Probate, Divorce, and Admiralty Division. A decree of divorce may now be pronounced by a single judge, trying the case with or without a jury; but the decree is a decree *nisi* (i.e. a decree, unless cause be shown to the contrary), which cannot be made final until six months have elapsed. A husband may obtain a divorce on the ground of his wife's adultery; he may also obtain damages against the co-respondent. Till 1923 a wife might obtain a divorce on the ground of the husband's adultery only if aggravated by cruelty, incest, bigamy, rape, &c., or by desertion without cause for two years. The law was therefore unequal as between husband and wife; a reason given for the inequality was that unfaithfulness on the part of a wife throws doubt on the legitimacy of the children of the marriage, while unfaithfulness on the part of the husband does not. A strong commission, presided over by Lord Gorell, considered the whole subject, and in 1912 reported in favour of equality of the sexes, and of greater facilities for the poor. The majority favoured extension of the grounds of divorce. Bills framed to give effect to the commission's recommendations failed to become law; but the Matrimonial Causes Act (1923) placed the wife on the same footing as the husband. Mere desertion, however long continued, is not ground for a divorce, but for an action for restitution of conjugal rights. The husband may be ordered to pay an alimentary allowance to his divorced wife; and the court may make orders in respect of the custody, maintenance, and education of the children of a dissolved marriage. A petitioner who is himself or herself in fault is not entitled to the remedy of divorce; thus, the petition of a husband may be dismissed on the ground of recrimination, if he has himself been unfaithful; and if the wife, as sometimes happens, refuses to press the countercharge, it may be the duty of the King's Proctor to intervene and call the attention of the court to the facts. The petition may also be dismissed on the ground of collusion or connivance, if, for example, the husband has encouraged another man to make improper advances to his wife; or on the ground of condonation, if he has continued to cohabit with her after discovering her offence. Similar rules apply to the petition of a wife. The confession of an accused party is evidence against him or her; but proof of this nature ought to be received with caution. If the respondent is of unsound mind, and therefore unable to plead, the petitioner will not be allowed to proceed with his case. Divorced persons are free to marry again; they cannot require a clergyman of the Church of England to marry them; but a clergyman who refuses must permit the use of his church for the purpose.

In Scotland, since the Reformation, the courts

have decreed divorce, on the petition of either spouse, on the ground of adultery. An Act of 1573 makes desertion without cause for four years a ground for an action of adherence; and, if redress is not obtained by that means, decree of divorce may be pronounced. It is not permitted that marriage should take place between offending parties. In case of divorce, the offending party forfeits all pecuniary benefit which might accrue from the marriage (see ALIMENT). Separation may be obtained on the ground of ill-usage, and perhaps desertion. Bars to divorce are condonation, connivance, collusion, but not recrimination.

In France divorce was established during the Revolution, abolished under the Empire, and restored by a law of 1884, which permits husband or wife to claim a divorce on the ground of adultery, cruelty, or conviction for any infamous crime. In most Protestant countries divorce is granted for adultery, and other reasons. In all Mohammedan countries divorce is extraordinarily easy for the husband, a few words of repudiation practically sufficing to loose the marital bond.

In America the laws of the States vary. In South Carolina divorce is entirely unknown. In most of the States, adultery, ill-usage, and desertion are now regarded as good reasons for divorce; in some, drunkenness, imprisonment, and even incompatibility of temper are added to the list. There are in the United States no ecclesiastical or other specially constituted matrimonial courts; as a general rule, the civil courts have jurisdiction to dissolve the marriage of a party who is a citizen thereof, or domiciled therein.

Questions frequently arise as to the competency of a court to annul a marriage contracted in another country on grounds which would not in that country be regarded as sufficient. As a general rule, the courts of a country have jurisdiction in matrimonial causes over all persons *bond fide* domiciled therein. But the English courts would probably refuse to recognise the dissolution of an English marriage by a foreign court on grounds not held sufficient in England.

See S. B. Kitchin, *A History of Divorce* (1912); the Reports of the Divorce Commission (1912); also MARRIAGE, ADULTERY, HUSBAND AND WIFE, PARENT AND CHILD.

Dix, JOHN ADAMS, American statesman and soldier, born in Boscawen, New Hampshire, 24th July 1798, was appointed cadet in 1812, and lieutenant in 1814, and while on the staff of General Jacob Brown studied law, afterwards being admitted to the Washington bar. In 1828, with the rank of captain, he resigned his commission; in 1830 he was appointed adjutant-general, and from 1833 to 1840 was secretary of state and superintendent of schools for the state of New York. He was for four years a democratic United States senator, and secretary of the treasury from 1861 to the end of Buchanan's administration. At the outbreak of the civil war he raised seventeen regiments, and in July 1861, with the rank of major-general of volunteers, he took command of the Department of Maryland, where he rendered effective service to the cause of the Union; from 1863 to the close of the war he commanded the Department of the East. He was appointed minister to France in 1866, and elected governor of New York by the Republicans in 1872. He died in New York City, 21st April 1879. His memoirs were published (1883) by his eldest son, the Rev. Dr Morgan Dix.

Dixie, or **DIXIE'S LAND**, a term which came, by a popular error, to be identified with the South and Southern institutions during the civil war. It is derived from a Northern negro refrain, which was sung in New York about the beginning of the 19th century, and which expressed the supposed regrets

of the slaves of a man Dixie, who had shipped his slaves to the South as the abolition sentiment grew stronger. This rude chant afterwards was developed into the melody that for a time became the rival of *Yankee Doodle*.

Dixmuyde (Fr. *Dixmude*), a small town of West Flanders, on the Yser, was, with its church of St Nicolas, almost entirely destroyed in the Great War.

Dixon, WILLIAM HEPPWORTH, an English writer and traveller, was born in Manchester, 30th June 1821, early became a merchant's clerk, but soon determined to devote himself to a literary life. He had already written much, and even edited for two months a Cheltenham paper, when in 1846 he settled in London. In 1854 he was called to the bar, but did not practise. A series of papers, published in the *Daily News*, on 'The Literature of the Lower Orders,' and another on 'London Prisons,' attracted considerable attention. The latter reappeared in a volume published in 1850. Before this, but in the same year, he published *John Howard, and the Prison World of Europe*. It was with difficulty he could induce a publisher to accept it, yet when published it went through three editions in one year. Dixon now devoted himself principally to historical biography. In 1851 appeared the first edition of his *William Penn*, a work called into existence by the onslaught made by Macaulay on the eminent Quaker, in which Dixon undertook, not without success, to disprove the great historian's charges. In 1852 was published his *Life of Blake*, and in 1860 his *Personal History of Lord Bacon*, two works which were indeed popular, but failed to satisfy competent critics. From 1853 to 1869 Dixon was editor of the *Athenaeum*. His books of travel, all bright and interesting, include *The Holy Land* (1865), *New America* (1867), *Free Russia* (1870), *The White Conquest* (1875), and *British Cyprus* (1879). His *Spiritual Wives* he issued in 1868. Accused of indecency in his *Free Russia*, he brought an action for libel against the *Pall Mall Gazette*, and was awarded a farthing damages. His historical works include *Her Majesty's Tower* (4 vols. 1869-71), *The History of Two Queens* (Catharine of Aragon and Anne Boleyn; 4 vols. 1873-74), and *Royal Windsor* (1878-80). His novels are unimportant. He died suddenly in London, 27th December 1879.

Dixon Entrance, a strait on the west coast of North America, separating Queen Charlotte Islands from the Prince of Wales Archipelago, and so dividing British territory from a part of Alaska.

Dizful, a town in the Persian province of Arabistan, about 190 miles W. of Ispahan, on the river Diz, here crossed by a handsome bridge of twenty arches. It has over thirty-five sacred tombs, and nearly as many mosques; but half the town consists of subterranean excavations in the rock, on account of the heat. It has a large trade in indigo, and is noted for the manufacture of reedpens, which are exported to India and Constantinople. Pop. 35,000. Fourteen miles SSW. lie the ruins of ancient *Susa*.

Djerablus, or **JERABLUS**. See CARCHEMISH; also HITTITES.

Djezzar (i.e. 'butcher'), the name given, on account of his cruelty, to Achmed Pasha, famous for his obstinate defence of Acre against Napoleon I. He was born in Bosnia about 1735, and rose, through murder and treason, from the condition of a slave to be pasha of Acre. In the beginning of 1799 the French entered Syria from Egypt, and advanced from victory to victory till they reached Acre, which was laid siege to on the 20th March. By advice of Sir Sidney Smith, Djezzar was

induced to hold out; and such was the savage doggedness of his defence, that Bonaparte was obliged to retire on the 21st of May. He died at Acre in 1804.

Djibutl, or DJIBOUTI, a port on the Gulf of Aden, which, in 1890, superseded Obok (q.v.), on the opposite side of the Gulf of Tadjura, as capital of French Somaliland. The railway to Addis Ababa greatly increased its importance. Pop. 8000.

Djinn, or JINN. See DEMONOLOGY.

Dmitrieff, RADKO, general, born a Bulgarian in 1859, won the battle of Lule Burgas, but disagreeing with Ferdinand's policy, entered the Russian service, and in the Great War commanded in Galicia and later in the south.

Dmitrov, a town of Russia, dating from 1154, on a tributary of the Volga, 42 miles N. of Moscow, with some trade; pop. 10,000.

Dnieper (ancient *Borysthenes*), one of the large rivers of Europe, has its source, near the Volga and the Western Dvina, in certain swampy forest-lands in White Russia. It flows with a general southerly direction past Kiev, Ekaterinoslav, and Alexandrovsk to the Black Sea. Its embouchure (increased by the waters of the river Bug) forms a gulf nearly 50 miles in length, with a breadth of from 1 to 6 miles. Its principal affluents are the Desna and Soj from the east, and the Pripet, Beresina, and Druz from the west. The total length of the Dnieper is 1330 miles, and its drainage area embraces 245,000 sq. m. Some of the finest provinces of eastern Europe lie within its basin. At Dorogobush the stream becomes navigable, but below Kiev and at other points traffic is interrupted. Below Ekaterinoslav, indeed, there are no less than sixteen rapids in the course of about 25 miles; but these impediments to navigation have been overcome in part by blasting. The produce of the southern districts is usually conveyed down the river to ports on the Black Sea, but many vessels pass annually from the Dnieper to the Baltic by the Brest-Litovsk canal (50 miles) and other waterways. The important river-traffic is now mostly below Smolensk; the chief fisheries are between Kherson and the estuary. The stream is permanently bridged at Kiev only, but boat-bridges and ferries are numerous along its banks. At Smolensk, the waters of the Dnieper are frozen from November to April; at Kiev, they are ice-bound only from January to the end of March; and at Kherson the river is frequently open all the year. See KINBURN.

Dniester, a river, chiefly of Rumania and Ukraine, having its rise in the Carpathian Mountains, in Galicia. It separates Bessarabia from Podolia and Kherson, and enters the Black Sea by a shallow shore lake, 18 miles in length and 5 in breadth, between Akjerman and Ovidiopol. The total length of the Dniester is 650 miles, and it drains an area of nearly 30,000 sq. m. Its current throughout is very rapid, and after reaching its easterly bend, rushes muddy and turbid through a broad, flat plain. The navigation is interrupted by a series of falls and whirlpools near Jampol. Wood and grain are the chief products conveyed down the river. Fishing-villages are frequent along its banks in Bessarabia.

Do'ab (from the Sanskrit, 'two rivers; cf. Punjab) is a term used in India for the country between any two rivers, but specially the space inclosed by the Jumna on the south-west and the Ganges on the north-east—a space extending from Allahabad to the base of the Himalayas, a distance of upwards of 500 miles, with an average breadth of 55 miles. It is the granary of Upper India, its great natural fertility having been increased by the

Ganges, Lower Ganges, and Eastern Jumna canals, and the extensive irrigation system which these render possible. It is all well cultivated, and is densely peopled throughout.

Dobell, BERTRAM (1841-1914), after hard struggles set up a small stationer's and news-vendor's shop in Kentish Town, from which developed his well-known book-shops in Charing Cross Road. He was the friend and discoverer of the second James Thomson, and had extraordinary success in bringing to light old literature of importance. His great find was Thomas Traherne. Smaller achievements were William Strode, and an unknown text of Sidney's *Arcadia*. He wrote *Sidelights on Charles Lamb*, and three volumes of original poems.

Dobell, SYDNEY, poet, was born at Cranbrook in Kent, 5th April 1824. His father, a wine-merchant, removed to London about 1825, and in 1835 to Cheltenham; with Gloucestershire and with his father's business Sydney's whole after-life was connected. Under the influence of a sect, the 'Freethinking Christians,' founded by Samuel Thompson, his grandfather, he developed a hot-house precocity, and at fifteen became engaged to the girl whom he married at twenty. He never quite recovered from a severe illness (1847); and the chief events of his life were visits in quest of health for himself or his wife to Switzerland (1851), Scotland (1854-57), and Cannes, Spain, and Italy (1862-66). He died at Barton End House, among the Cotswold Hills, 22d August 1874. His principal works are *The Roman*, by 'Sydney Yendys' (1850); *Balder* (Part I. 1854); *Sonnets on the War* (1855), in conjunction with Alexander Smith; and *England in Time of War* (1856). The first and the last achieved a success to wonder at. For though some of his lyrics are pretty, though his fancy is ever sparkling and exuberant, his poems as a whole are nerveless, superfine, grandiose, transcendental. 'Spasmodic' does hit them off better than comparison either with Shelley or with Donne. Professor Nichol edited his collected poems in 1875, and his prose works in 1876 as *Thoughts on Art, Philosophy, and Religion*. See his *Life and Letters* (2 vols. 1878), and the memoir by W. Sharp prefixed to his selected poems (1887).

Döbeln, a town of Saxony, on an island formed by the Mulde, 40 miles SE. of Leipzig by rail, with foundries, and manufactures of fire-engines, machines, cigars, cloth, leather, sugar, carriages, and pianos. Döbeln dates from the 10th century, and in spite of its sufferings at the hands of the Hussites and in the Thirty Years' War, has preserved a number of interesting old buildings. Pop. 20,000.

Do'beran, a favourite bathing-resort of Mecklenburg-Schwerin, 2½ miles from the Baltic, and 25 miles NE. of Wismar by rail. It has a palace, dating from 1232, a large bathing establishment, and a chalybeate spring. Pop. 5000.

Döbereiner, JOHANN WOLFGANG (1780-1849), professor of chemistry in Jena, and friend of Goethe, is remembered for what is called *Döbereiner's Lamp*, a piece of platinum sponge which ignites a jet of hydrogen in the presence of oxygen.

Dobritsch. See BAZARDJIK.

Dobrizhoffer, MARTIN (1717-91), born at Gratz, became a Jesuit in 1736, and from 1749 worked for eighteen years as a missionary among the Guarani and the Abipones of Paraguay. Afterwards he lived in Vienna, a friend of Maria Theresa. He was praised by Southey, and his *Historia de Abiponibus* (1784) was translated (1822) by Sara Coleridge.

Dobrovsky, JOSEPH, the founder of Slavonic philology, was born 17th August 1753, at Gyermet,

near Raab in Hungary, where his father, a Bohemian by birth, was stationed in garrison. He studied mainly at Prague, in 1772 entered the Jesuit order, and was successively a teacher, a family tutor, and the editor of a critical journal. In 1792, at the expense of the Royal Bohemian Scientific Society, he made a journey to Denmark, Sweden, and Russia, to search after the fate of those Bohemian books and MSS. which the Swedes had carried off from Prague during the Thirty Years' War. Till his death, January 6, 1829, he was reckoned one of the highest authorities on all matters connected with Bohemian history and literature. Among his works are *Scriptores rerum Bohemicarum* (1784), a history of the Bohemian language and literature (1792), a German-Bohemian dictionary (1802-21), *Glagolitica* (1807), and *Institutiones Linguae Slavonicae* (1822). See his *Life* in German by Palacky (1833).

Dobrudja (also spelt *Dobruđscha*, *Dobrutcha*, or, by Rumanians, *Dobrogea*), the south-eastern portion of Rumania, between the lower Danube and the Black Sea, transferred to the kingdom by the Berlin Congress of 1878, which fixed the southern limit at a line from Silistria on the Danube to Mangalia on the sea-coast. A slice from Bulgaria was added by the war of 1913. The north-east of this region is occupied by marshes and the delta of the Danube; the rest mostly a treeless steppe, too dry for farming, on which large herds of cattle, horses, and sheep are raised. The climate is malarious and unwholesome, and the inhabitants are a feeble folk. Rumanians and Bulgarians are the most numerous; many Circassians formerly settled here, Tatars and Turks having since 1878 gone to Turkish territory; but there are still many Turks and Russians, and some Germans.

Dobson, HENRY AUSTIN, poet, was born at Plymouth, 18th January 1840. He was educated at Beaumans, Coventry, and Strasburg, and at first intended to follow the profession of his father—a civil engineer—but in 1856 entered the Board of Trade, where he remained till 1901. In poetry he practised especially the more artificial forms of French verse, the rondeau, the ballade, and the villanelle. In these he showed rare perfection of form, often informed with true natural pathos, and revealed genuine satirical strength. His chief collections of verse are *Vignettes in Rhyme and Vers de Société* (1873), *Proverbs in Porcelain* (1877), *At the Sign of the Lyre* (1885), *The Sundial* (1890), *Beau Brocade* (1892), *The Story of Rosina* (1895), and *Carmina Votiva* (1901). The *Old World Idylls* (1883) consisted in great part of pieces selected from the first two. A collected edition of his poems was published in one volume in 1897. In prose Dobson published *Lives of Hogarth, Fielding, Steele, Bewick, Goldsmith, Horace Walpole, Richardson, Fanny Burney* (1903), and others. He wrote the critical notices of Hood, Gay, Præd, and Prior for Ward's 'English Poets' (1880); contributed articles on the three last named, and on Fielding, Goldsmith, Hogarth, and Richardson to *Chambers's Encyclopedia*; and edited *Eighteenth-century Essays* (1882), *Gay's Fables* (1882), *The Vicar of Wakefield* (1883), *Le Barbier de Séville* (1884), *Selections from Steele* (1885), and *Fanny Burney's Diary and Letters*. His *Eighteenth-century Vignettes* appeared in 1892-96, *A Paladin of Philanthropy* in 1899, *Side-walk Studies* in 1902, *Rosalba's Journal* in 1915, *Later Essays* in 1921. He died 2nd September 1921.

Dobson, WILLIAM, portrait-painter, was born in London in 1610, and succeeded Vandyck as king's serjeant-painter and groom of the privy chamber. He attended the king at Oxford, where he painted his portrait, and those of the Prince of Wales, Prince

Rupert, and other members of the court. The disturbances of the time and his own careless habits threw his affairs into confusion, and he was imprisoned for debt, and died in poverty, 28th October 1646, shortly after his release. His finest portraits are lifelike and well executed, resembling those of Vandyck. Examples are preserved at Coombe Abbey, Bridgewater House, Devonshire House, the National Portrait Gallery, and at Hampton Court, where is the excellent painting of himself and wife.

Docetæ (from the Gr. *dokēō*, 'I appear or seem') was the name given in the early church to those heretics who held that the human nature of Jesus Christ was a semblance and not a reality. The docetic tendency originates in the oriental and Alexandrian notion that matter is as such imperfect and impure; and the Gnostic and Manichean heretics found it impossible to conceive the essential union of the divine nature with a body composed of matter. The difficulty was got over in one of three ways: the body of Christ was either considered a real earthly body, but not belonging essentially to his nature, and only assumed for a time; or it was declared to be a mere appearance or illusion (as by Marcion, the Ophites, the Manicheans); or, finally, it was believed to be a heavenly body, composed of ethereal substance, though having the appearance of being material (as by Basilides, Bardesanes, Tatian, Valentine). Clement of Alexandria and Origen are most free from traces of Docetism; the Priscillianists and Bogomiles may be reckoned amongst the Docetæ. See Gnosticism, and the works on the History of Dogma.

Dock. The large genus *Rumex* of the order Polygonaceæ is usually divided into Docks and Sorrels, the latter distinguished not only by their peculiarly acid taste, but by hastate leaves and usually dioecious flowers (see *SORREL*); those of the docks proper being generally hermaphrodite. They are large perennial herbaceous plants, natives chiefly of temperate climates, with large generally lanceolate or ovate leaves, and panicles of small greenish flowers. They have great tap-roots, and are with difficulty eradicated from pastures. They also multiply rapidly by seed. The best mode of dealing with them is generally found to be repeated cutting away of their leaves and shoots, by which the plants are killed. Many of the species prefer watery places. Several of the European ones have found their way to North America, where they have reinforced the indigenous species as troublesome weeds. The large astringent roots of various species, notably of the Great Water-dock (*El. Hydro-lapathum*), as also of the Monk's Rhubarb (*El. alpinus*), were much esteemed in medicine until superseded by more powerful remedies. They have also been used in dyeing.

Dock, an inclosure for the accommodation of shipping, of which there are three principal types—wet docks, with entrances that can be closed; tidal docks, being harbours or basins with unclosed entrances; and dry, or graving, docks, to contain a vessel out of the water for repair. Floating docks are a type of dry dock.

At most ports, and particularly at British ports, a system of either wet or tidal docks is required, in order to provide the necessary sheltered quayage-space for shipping. There are, however, certain ports naturally endowed with a large and more or less sheltered deep-water basin, small tidal range, and absence of strong currents; and at such ports, as, for example, New York, the construction of wet or tidal docks is not required. But dry or floating docks are a necessary part of the equipment of every large modern port.

It is at ports where there is a great rise and fall

of tide, such as Liverpool or Bristol, where the range of tide is over 30 feet, or on the Thames, where it is over 20 feet, that wet docks are most necessary. When the range of tide is small, however, as on the east coast of North America, where it varies from 1 foot 8 inches at Baltimore or Galveston to 9 feet 6 inches at Boston, there are no wet docks, strictly speaking, but simply tidal basins excavated to a great depth under the low-water level. As the cost of dock walls and quays increases enormously with each additional foot of depth of foundation, it will be understood that, where there is a large tidal range and where shipping of great draft is to be accommodated, a tidal quay-wall will be very costly in comparison with a wet dock quay-wall, which would be less in height usually by nearly the amount of the tidal range. Owing to the increased draft of shipping in recent years, engineering costs govern the choice between the two types even more largely than hitherto. Generally at ports where the tidal range exceeds about 12 feet, a system of wet docks is constructed in preference to a system of tidal basins or open quays.

Wet docks are basins in which the water is maintained at a level nearly constant, being usually that of high-water of the tide. Entrance is generally gained by means of a Lock (q.v.), having two sets of gates separated by the length of the largest vessel using the dock. Vessels can thus enter or depart during a considerable period when the state of the tide outside is within a few feet of the level of the water in the dock. Occasionally arrangements for locking can be made to pass in vessels at any state of the tide. Frequently, for the sake of economy both in space and in cost, locks have only one set of gates, so that vessels can enter or depart only at or very near the hour of high-water.

The use of wet docks enables vessels always to keep afloat, thus avoiding straining by taking the ground; also, they save vessels from moving vertically up and down the quays with the rise and fall of the tide, thus securing that the quays shall not be sometimes too high and at other times too low for convenience in shipping and discharging cargoes. On the other hand, time required to lock vessels out and in wet docks, and the trouble of entering the dock, are inconveniences.

Wet docks are usually surrounded by quay or wharf walls of masonry or concrete, but where the chief purpose is for laying up vessels and not for loading or unloading, the shore-margin is sometimes only a natural sloping beach. For keeping up the water-level in a wet dock pumping is sometimes resorted to, but feed-water reservoirs are occasionally constructed. The tendency of the bottom to silt up by deposits of fine mud is of common occurrence, particularly in some situations, and dredging or some other means must be employed from time to time to keep the dock reasonably clear. Small docks are occasionally emptied for the purpose of cleaning. Dock-gates, when on a small scale, are opened and closed by means of chains worked by hand, but when on a large scale they are operated by hydraulic or electric machinery. Small dock-gates are constructed of timber, but wide and deep dock entrances are closed either by steel gates or by a single steel caisson or sliding door.

An example of a large modern wet dock is the new Royal Albert Dock, London. The new wet dock extends over an area of 64 acres, has a length of 4500 feet, a breadth varying from 500 feet to 700 feet, and a depth of water of 38 feet over the greater part of its area. The design provides berth accommodation simultaneously for fourteen of the largest ships entering the Port of London. Entrance from the river Thames is gained through a lock 800 feet long by 100 feet wide, divisible into two

compartments and controlled by three pairs of hydraulically operated steel gates, while a passage-way 100 feet wide connects the former Albert Dock with the new dock. A conspicuous feature is the increased quayage obtained by the construction parallel to the south wall of seven reinforced concrete jetties, each 520 feet long, and connected with the quay by a bridge, thus allowing barges to pass freely between the jetties and the quay wall. The jetties are equipped with cranes of various capacities, chiefly 3-ton, electrically operated, with an outreach capable of transferring cargoes from vessels either into barges lying alongside the quay or on to the quay itself. Two auxiliary self-propelled floating derricks of 100 tons and 10 tons capacity deal with unusually heavy loads. Extensive storage accommodation is provided, with rail and road facilities. On the north side there are three two-storey reinforced concrete warehouses, each 1100 feet long by 120 feet wide, and on the south side there are seven single-storey steel sheds, from 480 feet to 520 feet in length and 120 feet in breadth. A graving dock, 750 feet long, is situated at the end of the wet dock, and is fitted with extensive ship-repairing plant. This dock is emptied by electric pumping machinery of 1750 horse-power, discharging the water through two pipes 48 inches in diameter.

An instance of a wet dock designed for a particular trade is that constructed at Ellesmere Port, at the sea end of the Manchester Ship Canal. This dock is designed specially for the safe handling of highly inflammable oil traffic. Every care has been taken in its lay-out and construction to prevent outbreak of fire. The dock is in an isolated situation on the north side of the canal, and is capable of accommodating one large oil-tank ship, and for easy access is placed at a convenient angle with the canal. The dimensions are: length, 600 feet; width, 100 feet; depth of water, 30 feet; and width at entrance, 80 feet. In order to prevent spread of burning oil or escape of oil, the vessel to be discharged is shut off from the canal traffic by means of a floating reinforced concrete caisson, 82 feet 6 inches long, placed across the dock entrance. The depth of caisson is only 10 feet. While the vessel is discharging no fires or lights are permitted on board, and the crew is removed. Steam generating plant ashore supplies steam through underground pipes to operate the ship's pumps for discharging the oil. The storage-tanks belonging to various oil companies being on the south side of the canal, the oil supply-pipes are led under the bed of the canal by a tunnel, 6 feet in diameter and 466 feet long, cut in sandstone. The tunnel terminates in a vertical shaft 60 feet deep at each end, the one shaft being 6 feet and the other 8 feet in diameter.

Tidal docks require no particular description; they are merely basins surrounded by quay-walls, and having open entrances permitting the free ebb and flow of the tide, as at Glasgow, Greenock, Shanghai, and Southampton. The Port of Glasgow consists of a series of tidal docks, which are situated on the river Clyde some 15 miles above Greenock. Being of the open type, they are open to traffic at all states of the tide, and congestion in the channel at times of high-water is thus obviated. The total water-area of the port, only 75 acres in 1873, is now 540 acres, and the total length of quayage, which includes numerous wharfs on the river side, is about 11 miles. The largest docks are Princes Dock, Queen's Dock, and Rothesay Dock. Princes Dock has a water-area of 35 acres, and a quay area of about 40 acres, including sheds and roads. Three basins, together with a canting basin, have a depth of from 20 feet to 25 feet at low-water, or 12 feet deeper at high-water, and

give a combined quay length of 3737 yards. Berthage for vessels of the largest class is provided at the west quay, which is 1000 feet long. The cost of this dock, completed in 1897, was £996,000. Queen's Dock is on the north side of the river, opposite Princes Dock. The area covered by its

three basins is 34 acres, and the quayside is 3334 yards. The north quay is 1891 feet, and the south quay 1668 feet in length, and the general depth at low-water is 20 feet. The capital cost was £902,000. For coal and iron-ore traffic Rothesay Dock is situated several miles farther down the river from

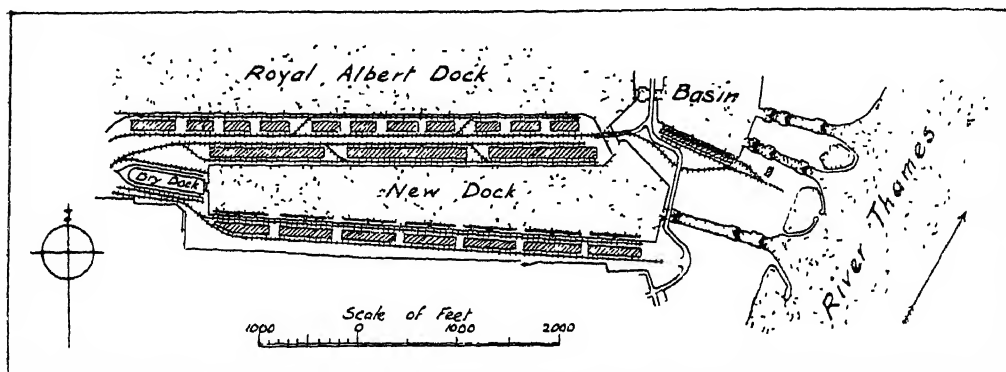

Fig. 1.—Plan of the Royal Albert Docks, London.

Glasgow. This dock has two basins, which together have an area of 20 acres, the inner basin being 1735 feet long, and the total quayside is 2045 yards. The depth of water is 25 feet at low-water, and 36½ feet at high-water. Rothesay Dock was opened in 1907 at a cost of £574,900. In addition to the large

number of privately owned graving docks on the river, there are three graving docks belonging to the port authorities, which are situated beside Princes Dock. New York Harbour forms a large natural tidal basin, the port works consisting of many narrow piers up to 1350 feet in length, and

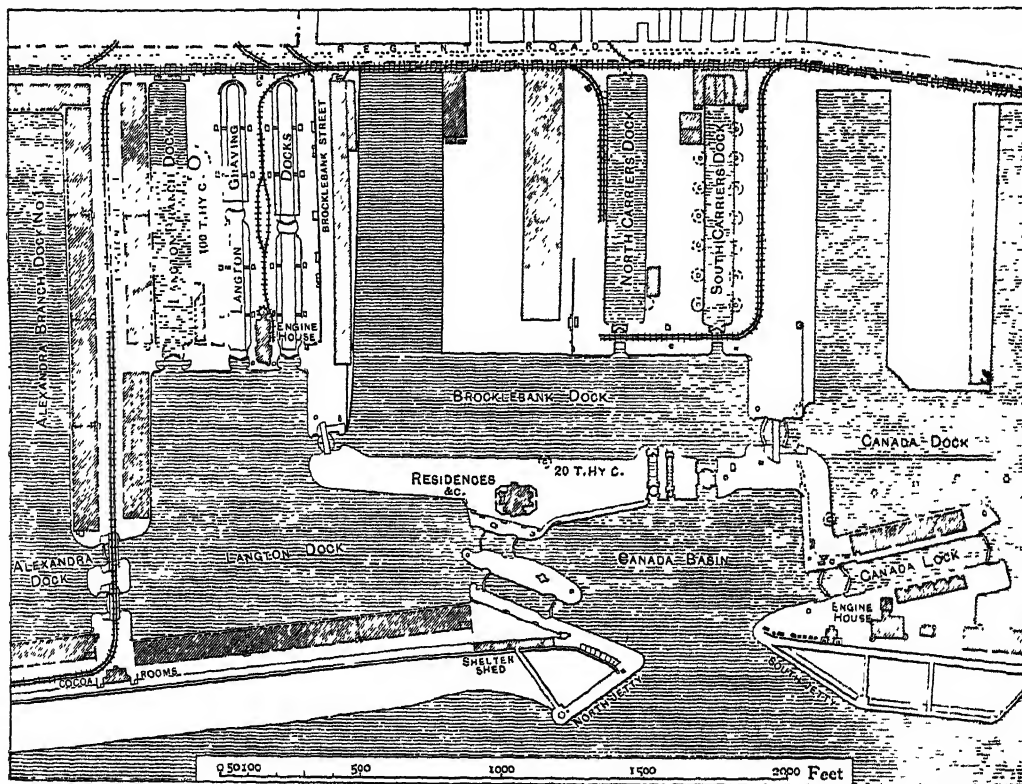

Fig. 2.—Plan of the Canada Basin and its connections, Liverpool.

200 feet in breadth, which, extending out to deep water, have hitherto provided all the quayside necessary for shipping.

With small ranges of tides, tidal docks are con-

venient for shipping if made deep enough to keep vessels afloat at low-water; but with tides of considerable range they are attended with the disadvantage of large vessels grounding at low-water,

and owing to the large volume of water, generally more or less turbid, which enters at every tide, they are much more liable to silt up than are wet docks. For removing muddy or soft deposits the plan is sometimes resorted to of releasing a reserve of water with a sudden gush from an inclosure at the inner end of the dock. This scouring action is usually confined to clearing small docks or basins and their approach channels, and the method is of most effect when carried out about the period of three-quarters ebb of the tide.

Dry docks or graving docks are used for the purpose of laying vessels dry for examination or repairs. The earliest graving dock was a bed or 'grave' dug on the shore for receiving a vessel at high-water or spring-tides, the excavations being then protected from ingress of water by an artificial bank thrown up at time of low-water. As ships increased in size, dry docks became essential works, and all modern ports, dockyards, and ship-repairing establishments are equipped with a generous supply of dry docks. A dry dock, however, rarely earns any reasonable interest on its cost. It is remarkable that the first principles involved in early dock construction still obtain, development being confined to larger dimensions, details of construction, and elaboration of equipment.

Dry docks may have their entrance either from

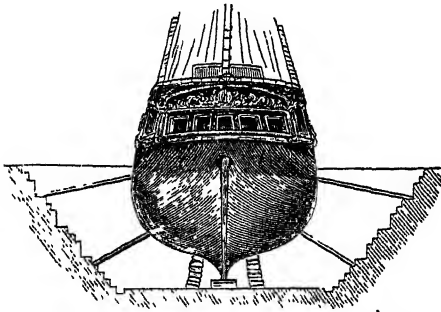

Fig. 3.—Section showing principle of Dry Dock.

a wet dock or from a tidal harbour or sea or river, but the former is usually the more convenient arrangement, as it admits of vessels being docked or taken out independently of the state of tide and free from the disturbance of currents, and gives more economical design of entrance and gates. These dry docks are built of good water-tight masonry or of concrete. The entrance is closed by means of a Caisson (q.v.) or by a pair of folding gates, pointing outwards to exclude the water. When the tidal range is great, the bottom of the dock may be placed above low-water level so that the dock can be run dry without pumping, but generally, when the rise of the tide is small, the bottom is well below that level, in which case pumping is required for emptying the dock in about three hours. The floor may be level or may slope slightly for drainage purposes towards the sides and entrance. The keel of the vessel to be docked rests on wooden blocks fastened down to prevent them floating, and built up to such a height, about 5 feet, as to admit of the shipyard workers getting under the vessel's bottom. Side-shores are put in to keep the vessel in an upright position, and blocks are fitted under the bilges as soon as possible after the water-level has been lowered. The sides generally consist of stone steps, called altars, the purpose of which is to fix the lower ends of the shores and also for the convenience of supporting the workmen's scaffolds. Dock sides are now usually steeper than shown in fig. 3, the use of altars being modified, and the lower part of the wall being vertical. Dry docks

may be made long enough to hold several vessels at one time, being divided longitudinally, but it is a more economical arrangement to have a system of several docks of different dimensions. The same pumping-machinery and other equipment, such as an unusually large crane, can be made to serve two docks if they are built close together in parallel. A dry dock is now frequently designed so as to allow for future extension, and in several British docks the caisson at the entrance is arranged to give additional length for accommodating a particularly long vessel.

In addition to adequate pumping-machinery, dry docks are equipped with cranes of various outreach and power, capstans to assist in making the entrance, and entrance gate-opening machinery. The operating power is hydraulic or electric, and a supply of water, light, steam, and power for riveting, &c., is available all over the dock area. The workshops should be arranged close to the dock.

The following table gives the dimensions in feet of various large British dry docks with depth over the sill at high-water of spring-tides :

	Length.	Breadth	Depth
Liverpool—Gladstone.....	1050	120	43
" —Canada.....	926	94	32
Southampton—Trafalgar.....	912	100	35
Thames—Tilbury.....	846	78	35
" —King George V.....	750	100	34
Immingham.....	740	56	23
Avonmouth.....	879	100	35
Clyde—No. 3.....	911	88	27
Belfast—Thompson.....	864	96	36
Rosyth—Naval.....	880	109	40

At the Port of Liverpool there are twelve dry docks that can hold vessels over 500 feet long. At Rosyth Naval Dockyard four dry docks can accommodate vessels over 830 feet long. One of the largest dry docks is at Taranto, in Italy. Its length of 820 feet can be lengthened to 1150 feet, its breadth at entrance is 134 feet, and depth 40 feet. At Havre a dry dock is 1030 feet long, 125 feet in breadth, and 28 feet deep at low-water spring-tides.

The use of the graving dock is frequently superseded in the case of small harbours by that of an inclined Slip (q.v.). These slips are also a useful adjunct to a general dock system, but they are seldom designed to accommodate vessels over 1500 tons.

Floating docks were originally built of timber and of small size, and are a development of the *gridiron* formerly used at several tidal ports. This consisted of a frame of timber, over which vessels were floated at times of high-water, and grounded upon it during the ebb tide. A partial examination was then made at low-water, prior to dry docking of the vessel for repairs, if seen to be necessary. The earliest floating docks took the form of a large timber box, with a flap door falling down at one end, which was closed after entrance of a vessel, and the water was pumped out. On account of their lack of stability, and from the fact that they could be used only in shallow water, the use of the timber dock was limited, but the introduction of iron for shipbuilding rendered practicable the construction of floating docks of large dimensions, and capable of working in deep water.

The early history of floating docks is marked by the numerous accidents which accompanied their development. Some were wholly lost by storm or capsizing, or proved unmanageable when completed. Even at the present day the slow process of towing a floating dock in the open sea, as frequently has to be done, from its place of construction to its destination, is attended with great difficulty and

considerable chance of disaster. Though few are in existence in Britain, the floating dock has several advantages over the graving dock, which may make it more suitable for particular port conditions. It can be more quickly built, is cheaper, and its cost is accurately known, there being no uncertain foundations to be dealt with. It is cheaper and requires less pumping. It can be more easily lengthened, and its position can be changed; and, if it becomes unsuitable, it can be sold. On the other hand, it requires a wide and deep basin to lie in. It is not so accessible for workmen, being off-shore, and its equipment in large cranes and convenience of workshops cannot be so complete. Its moorings are of difficulty, and it may require extensive repairs.

Large British floating docks are the naval docks on the Tyne and at Portsmouth, which are capable of lifting 32,000 tons, being 680 feet long and 113 feet wide at entrance, with available depth of 36 feet when submerged. Floating docks have been built with lifting capacities of 45,000 tons, and even of 60,000 tons.

Dockisation, or the conversion of tidal rivers into wet docks, may sometimes be carried out with advantage in suitable conditions. The water-level at the quays is held up by the construction across the river of a barrage with entrance-locks. Where more depth at low-water is required at the river quays, dockisation may render unnecessary extensive dredging, thus exposing existing quays to less risk than would be the case if dredging were resorted to, possibly below the levels for which they were designed. The enormous expense of wholesale reconstruction of quayage is thereby avoided, but the advantages or otherwise of the dockisation of British tidal rivers is one of the subjects on which, in recent years, there has been shown to be much difference of opinion among engineers.

Cost of docks, as already stated, varies greatly with additional depth of foundation of the quay-walls, and has even been estimated as varying as the cube of the depth available for shipping. The problem of providing facilities at a port for larger ships has frequently to be faced, and it is a serious one for dock authorities, as the necessary works are usually clearly unremunerative, and, as the largest vessels trading to any port are few in number as compared with the average-sized vessels trading, the cost will fall to be met by the smaller trading vessels. The two large commercial vessels, the *Majestic* and the *Leviathan*, the former being 915 feet long, 100 feet beam, and 39 feet draft loaded, can be accommodated at only one British graving dock—the Gladstone Dock at Liverpool. But ports intending to attract in the near future the largest vessels are looking to having to provide docks and facilities for ships of 40 or even 45 feet draft.

The cost of dock construction varies greatly at different ports, the depth and nature of the foundation for the quay-walls being the main items governing the cost. On the Clyde, quay-walls have cost about £40 per lineal foot of length for 60 feet depth of wall, and this cost is half that of a quay-wall of approximately similar depth at Antwerp. The cost of a quay-wall of over 70 feet deep constructed at Southampton, where unusual engineering difficulties of construction had to be faced, has been calculated at about £150 per lineal foot of length of wall when completely equipped.

Dock equipment is of extreme importance to shipping, and its adequacy is essential at a large modern port. The requirements of shipping, so far as docks are concerned, are: ease of access from sea to ample sheltered quayage, speedy facilities for loading and discharging cargoes, for transport to and from the quays, and for bunkering, provisioning, and repairs. The enormous expense of dock extensions can frequently be avoided by improved facilities in equip-

ment, which are particularly called for, owing to increased wages and labour difficulties at ports. The tonnage dealt with at many ports is now enormous. At Glasgow over 10 million tons of goods are dealt with annually, and the annual income from dock dues amounts to over one million pounds. For Liverpool the corresponding figures are 50 per cent. greater.

The method of dealing with cargoes differs at the various ports. It can be discharged straight on to the quays, as at Liverpool, being delivered directly into railway waggons or other vehicles for land transport. It can be dealt with by water transport, the vessel discharging into lighters alongside, as is the procedure with a large proportion of cargoes at London. In the case of the extended Albert Dock, the system of discharge is a combination of both methods, the ship's gear discharging into lighters and the dock gear discharging ashore.

A usual manner of dealing with general cargoes is with quay cranes of under 3 tons capacity with net slings—one crane opposite each hatch. The average weight of most packages is under 30 cwt., and larger loads can best be taken by floating cranes of from 3 to 20 tons capacity. At Liverpool, self-propelling floating cranes have been provided for lifts up to 200 tons. 2000 tons a day is a good rate of discharge for general cargoes.

Particular bulk cargoes where the quantities are large, goods about the same dimensions, and traffic is regular, are best dealt with by special appliances. Grain can be dealt with by conveyor belts, or probably best by pneumatic suction. For discharge the grain can be sucked from hold, automatically weighed, and delivered loose into barges or directly into sacks. At Montreal, grain elevators can deliver 80,000 bushels per hour, and a vessel can be loaded up under twenty-four hours with a full cargo of, say, a quarter of a million bushels. At Sydney, the grain silos have a capacity of 6½ million bushels. Frozen meat is dealt with by conveyor belt between ship and special storage sheds. Coal is dealt with by grabs or by raising and tipping the railway waggons. In discharging oil a pipe line can be laid under water and the oil can be pumped ashore, the vessel anchoring at a dolphin at the end of the pipe line. Other bulk cargoes frequently handled by special means are ore and timber. Cargoes of bananas from the West Indies are handled by special arrangements at Avonmouth.

Most dock appliances are best operated by electricity, which gives power usually always ready, and affords greater flexibility of movement for cranes and greater economy when operating at loads less than the maximum.

See *Proceedings of the Institution of Civil Engineers*.

Docket (from the same root as *dock*, 'to cut off or clip'), a small piece of paper or parchment, containing a brief or summary of a large writing. All attestations or declarations annexed to written instruments are called dockets, more particularly those that are done by a Notary (q.v.).

Dock Warrants are orders or authorities for the removal of goods and merchandise warehoused in the various docks. The orders are granted by the proper officer at the docks, on application of the importer, in favour of any one whom the latter shall name. Careful rules as to obtaining warrants are laid down by the East and West India Dock and the London Dock Companies. These rules are, in a great measure, followed by the other dock companies in the kingdom. Unless the rules are complied with, goods will not be delivered from the docks. Warrants may be obtained for either the whole or a part of a cargo consigned. A warrant may be assigned by the holder. A single warrant may also, at the desire of the holder, be

divided into smaller warrants, and these also may be assigned. In case a warrant is lost, a new warrant will not be issued till the loss has been advertised, and the holder furnish the company with an engagement to indemnify them for any loss which may arise.

Dockwra, or DOCKWRAY, WILLIAM, a merchant who in 1683 devised a new penny postal system in London, was alternately favoured and persecuted by the authorities, and died in poverty about 1702. See POST-OFFICE.

Dockyards. Under the names of the several towns where the royal dockyards are situated those establishments are briefly noticed.

A large number of men-of-war are built by the government at one or other of the dockyards at Portsmouth, Plymouth, Sheerness, Chatham, and Pembroke; but Rosyth dockyard is principally used for repairs. Each of these establishments comprises slips on which the ships are built, docks in which they are kept, and all the appliances for fitting them out for sea. Boat-building and mast-making are also carried on; and in some, though not all of the yards, rope-making, sail-making, anchor-forging, block-making, and other manufacturing operations connected with the finishing and furnishing of ships. There are also arrangements connected with the storing of guns, torpedoes, and other munitions of war. At Plymouth, Gosport, and Deptford are large establishments for victualling the navy; while machinery is repaired and constructed in the dockyards proper. To enable ships to be repaired and refitted abroad, there are royal dockyards at Gibraltar, Malta, Bermuda, the Cape of Good Hope, and Hong-kong. Dockyards are maintained by the various Dominion authorities at Sydney, Halifax, Esquimaux, and Bombay. Haulbowline is now maintained by the Irish Free State authorities. Since the creation of a steam-navy, and the large substitution of iron for wood in shipbuilding, an increasing proportion of the royal ships are built in private yards. All the royal dockyards are under the Admiralty, and each is governed by a distinct set of officers responsible only to that department. The chief officer, called the superintendent, is always a naval officer—an admiral at the larger yards, a captain at Sheerness and Pembroke. The superintendent controls all the other officers, and all the artificers and labourers employed; examines the accounts, authorises the payments, and is responsible for the stores. When a new ship is to be built, or other work executed, the superintendent receives general instructions from the Admiralty, while special instructions are conveyed to other officers more immediately concerned with the actual working. Engineers and electricians form an important part of the establishment. The artisans of the dockyards comprise shipwrights, platers, blacksmiths, caulkers, joiners, smiths, millwrights, block-makers, sail-makers, rope-makers, &c.; while under these is a large body of labourers.

The general direction of the royal dockyards is under the superintendence of the Controller of the Navy, under whom are many professional and technical officers. See also COALING STATIONS.

In the United States there are 'navy yards' and naval stations. *Navy yards* are Boston, Mass.; Charleston, S.C.; Mare Island, Calif.; New York, N.Y.; Norfolk, Va.; Philadelphia, Pa.; Portsmouth, N.H.; Puget Sound, Wash.; Washington, D.C. *Naval stations* are Cavite (Philippines); Culebra (Porto Rico); Guam; Guantánamo (Cuba); Key West, Fla.; New Orleans, La.; Newport, R.I.; Pearl Harbour (Hawaii); St Thomas (Virgin Islands); and Tutuila (Samoa).

The great naval centres of France are Cherbourg, Brest, Lorient, Rochefort, and Toulon. Germany had till 1919 three ports of war—Kiel, Danzig, and Wilhelmshafen. Of these, Danzig was made a free town under the League of Nations. Trieste and Pola were the Austro-Hungarian naval harbours. These became Italian in 1919. Russia has Cronstadt and Nikolaiëff at home, and Vladivostok in Siberia. Italy has Spezia, Naples, Venice, Taranto, Castellamare, and Pola; Spain, Ferrol, Cartagena, and Cadiz. Japan has Yokosuka (destroyed by earthquake, 1923), Kure, and Sasebo. See ARSENAL.

Doctor (Lat. *docēre*, 'to teach'), a teacher. Originally the word doctor was used to signify a teacher in general, and it was not till the 12th century that it became the highest university title of honour for the learned. It had frequently appended to it in those early days some additional expression intended to characterise the peculiar gift of its possessor. Thus, Thomas Aquinas was called the Doctor Angelicus; Bonaventura, the Doctor Seraphicus; Alexander de Hales, the Doctor Irrefragabilis; Duns Scotus, the Doctor Subtilis; Roger Bacon, the Doctor Mirabilis; William Occam, the Doctor Invincibilis or Singularis; Joseph Gerson, the Doctor Christianissimus; Thomas Bradwardine, the Doctor Profundus; Adam Marsh, the Doctor Illustis; Raymond Lully, the Doctor Illuminatus; St Bernard, the Doctor Mellifluus; Henry of Ghent, the Doctor Solennis; and the like. Formal promotions to the university degree of *doctor legum* commenced at Bologna about 1130, and the learned Irnerius, the regenerator of the Roman law at that period, is said to have introduced the ceremonial which was afterwards universally adopted. The university of Paris almost immediately followed in the footsteps of Bologna. In England the doctorate was not introduced till the following century. Originally the degree, which is more modern than those of bachelor and master, was granted only in law and divinity; in medicine it was not granted till the 14th century; in philosophy, science, literature, and music, only quite recently. The doctor's degree is granted either on examination, and after the ancient form, at least, of publicly defending a learned thesis in Latin has been observed, or else it is an honorary degree, conferred in consideration of the general reputation of the recipient for eminence in some particular branch of learning, philosophy, or science. The doctorate of laws (whether in the form of LL.D., *Legum Doctor*; D.C.L., Doctor of Civil Law; or J.U.D., *Doctor Utriusque Juris*, Doctor both of Civil and Canon Law) is especially wont to be conferred on eminent men *honoris causa tantum*; the D.D. is often distinguished rather as a pastor or public man than as a divine; the doctorates of medicine, science, and music are usually for ascertained professional attainment. In Germany, learned ladies occasionally shared the honours of the doctorate; and now universities generally, there and elsewhere, give women doctors' degrees. It was a special honour to Cardinal Cullen that, before he was ordained priest, the pope conferred the doctor's hat on him with his own hand. See DEGREE, UNIVERSITY, WOMEN.

Doctors' Commons, formerly the college of the doctors of civil law in London, situated in St Bennet's Hill, St Paul's Churchyard. It was founded by Dr Henry Harvey, Dean of the Arches, in 1568, previous to which time the doctors had lived in Paternoster Row. The original building was burned in the great fire in 1666, when the doctors removed for a time to Exeter House. In 1672 the Commons was rebuilt, and the doctors returned to their former quarters. The college was incorporated by royal charter in 1768. The persons practising

in Doctors' Commons were the doctors, called in the ecclesiastical courts advocates, and the proctors, whose duties were analogous to those of solicitors. Both doctors and proctors were admitted by fiat of the Archbishop, and introduced to the Dean of Arches in court by two persons of their own degree, in their robes. The robe of the doctors was scarlet, with a hood trimmed with taffeta or white miniver. In 1857, on the establishment of the Divorce Court and Probate Court, the charter of Doctors' Commons was surrendered, and the corporation was dissolved, the advocates being merged in the general body of the bar, and the proctors becoming solicitors; the last-surviving advocate died in 1912. The courts which sat at Doctors' Commons were the Court of Admiralty (q.v.); the Prerogative Court, whose powers were transferred to the Probate Court; the Court of Delegates, whose powers are now exercised by the judicial committee of the Privy-council; and two other ecclesiastical tribunals, the Faculty Court and the Archdeacon's Court. The Court of Arches also sat in the same place. The buildings of the College of Advocates were demolished in 1867; and in 1874 the Doctors' Commons Will Office was removed to Somerset House.

Doctrinaire, a term used of pedantic and unpractical views, as opposed to a policy based on precedent, prudence, *laissez faire*, or expediency. It was applied in France, in 1816, by the reactionary court-party to those who supported scientific doctrines of constitutional liberty against the arbitrary will of the monarch. This party, which had its rallying-point in the salon of the Duc de Broglie, was led in the Chamber by Royer-Collard, and supported in the press by De Barante, Guizot, and Villemain. At the Revolution of 1830 they became the advisers of Louis-Philippe.

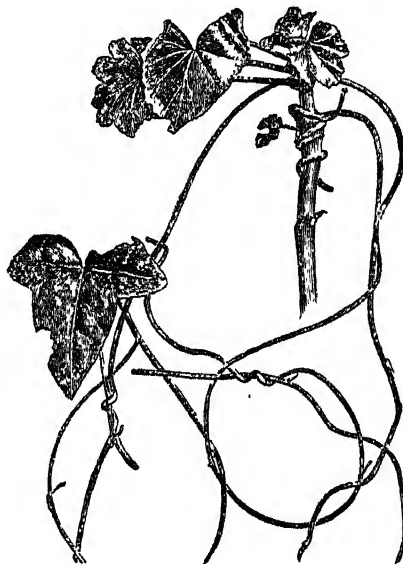

Doctrine. See DOGMA.

Dodabetta. See GHATS.

Dodd, WILLIAM, clergyman and forger, was born, 29th May 1729, at Bourn in Lincolnshire; entered Clare College, Cambridge, as a sizar, in 1746, and graduated as fifteenth in the mathematical tripos, 1749-50. Shortly after, he removed to London, married, took orders, and ere long became a popular preacher. His sermons in behalf of public charities were particularly successful; those preached as chaplain of the Magdalen Hospital attracted all the fashionable ladies of London. Dodd next published a series of edifying books, edited the *Christian Magazine*, and became in 1763 one of the king's chaplains, and soon after LL.D., and tutor to Philip Stanhope, nephew to Lord Chesterfield. His habits had always been very expensive, and his large income as a successful preacher and writer did not save him from drifting hopelessly into debt. He purchased Charlotte Chapel in Pimlico, and had all his wonted success, but an anonymous letter of his wife to the Lord Chancellor's wife, offering a large sum for the rich living of St George's, Hanover Square, led to Dr Dodd's name being struck off the list of chaplains (1774), and his wife's being taken off by Foote in a farce as 'Mrs Simony.' Dodd left England for a time, and was well received by his pupil, now Lord Chesterfield, at Geneva, and presented to the living of Wing in Buckinghamshire. After his return he sunk deeper and deeper into financial difficulties. He sold his chapel in 1776, and in the February of the following year offered a stockbroker a bond for £4200 signed by Lord Chesterfield. It was discovered that the signature was a forgery, and Dr Dodd was at once arrested. He refunded great part of the money, but was nevertheless sent to trial, convicted, and sentenced to death. Extraordinary efforts were made to secure a pardon; petitions and

pamphlets appeared in profusion, and even Dr Johnson, the most rigid of moralists, if the kindest of men, lent the unhappy man the great influence of his support. The sermon preached to his fellow-prisoners in Newgate and his final appeal to the king were both composed by Johnson, whose final letter to Dr Dodd, when his awful doom was certain, thrills throughout its grave phrases with profoundest pity. The king refused to pardon his former chaplain, and Dr Dodd was hanged, 27th June 1777. Of his numerous writings the *Beauties of Shakespeare* (1752) was long popular, and *Thoughts in Prison* is still interesting. See *A Famous Forgery*, by Percy Fitzgerald (1865).

Dodder (*Cuscuta*), a widely distributed genus of phanerogamous parasites, usually regarded as degenerate Convolvulaceæ, and forming the type of a small sub-order Cuscutaceæ. Being entirely parasitic, they have lost all trace of leaves, even the cotyledons of the embryo being no longer distinguishable, while chlorophyll is almost completely absent. The seed germinates very late in spring, and as the seedling rises from the ground its tip soon begins to show the sweeping movements of circumnutation of a climbing plant. If no host be

Dodder, attached to a Geranium and Ivy-plant.

in the neighbourhood for it to take up its quarters on, it falls to the ground, but retains its vitality for some weeks, by which time a victim may probably have germinated. As soon as it touches a living plant it twines firmly round it, and a series of small wart-like adventitious roots are developed, from the centre of each of which a bundle of suctorial cells force their way through the epidermis and cellular envelope into the bast, and press against the woody tissue of the host. The portion of the dodder stem below this attachment now dies off, and there is then no longer any connection with the ground. The growing point again circumnutes until it finds a new base of attachment upon the same or a different stem of the host, there to repeat the formation of suckers. In this way a tangled skein of threads is formed over which, late in the season, the flowers develop in dense clusters, and the ripened seeds are shaken out of the capsule by the wind, or gathered with the crop. This parasite is often very injurious, particularly in Germany, where the fields of flax, clover, and lucerne sometimes show well-marked

patches completely desolated by the pest; these have simply to be mown down and buried before new seed has set; while pains must be taken to procure clover-seed pure from those of the parasite. The temperate species are all annual, but *C. verrucosa* and other tropical forms are perennial. It is a remarkable circumstance that *Cassytha*, a totally unrelated oriental genus of Lauraceae, has not only assumed the same general mode of life and twining, leafless habit, but germinates and penetrates in a precisely similar way.

Doddridge, PHILIP, a great nonconformist divine, was born in London, 26th June 1702, the twentieth child of a well-to-do oilman of good descent. The Duchess of Bedford, to whom his uncle was steward, offered him an education at either university and provision in the church; but though dissuaded by Calamy, he determined to enter the nonconformist ministry on the advice of the famous Samuel Clarke. He was educated at a theological academy at Kibworth in Leicestershire (afterwards removed to Hinckley), presided over by John Jennings, a man not only of great intellect, but of uncommon breadth and toleration. In 1723 Doddridge became pastor of the dissenting congregation at Kibworth. After declining several invitations from congregations whose rigid ideas of orthodoxy he felt would be uncongenial to him, he settled in 1729 at Northampton as minister and president of a theological academy. Here he continued to preach and train young students for the ministry till shortly before his death, which occurred October 26, 1751, at Lisbon, whither he had gone for the benefit of his health. Doddridge was a man of the most amiable character, deep piety, and extensive accomplishments. He was at once liberal and evangelical, and with all his religious earnestness and enthusiasm had humanity enough for such 'levities' as cards and tobacco. His principal work is *The Rise and Progress of Religion in the Soul* (1745). His hymns have carried his name over the English-speaking religious world, perhaps the best known being 'Hark, the glad sound,' and 'O God of Bethel, by whose hand.' His *Correspondence and Diary* was edited by his great-grandson (5 vols. 1829-31). See also Stanford's *Memoir* (1830).

Dodecanese (Gr., 'twelve islands'), the islands of Kasos, Karpathos, Kharki, Tilos, Syni, Nisyros, Astropalia, Kos, Kalymnos, Leros, Lipsos, and Patmos, which, with Rhodes and Castellorizo, Italy seized in the war with Turkey, and retained as a pledge for the fulfilment of the terms of the treaty of Ouchy (1912). By the treaty of Sèvres (1920) all these islands were to be ceded to Italy, and by the Tittoni-Venizelos agreement of the same date (revoked by Italy in 1922), the Dodecanese was to be passed on to Greece. The treaty of Lausanne (1923) gave all to Italy. Area of the twelve islands, 455 sq. m.; pop. 64,000, nearly all Greeks.

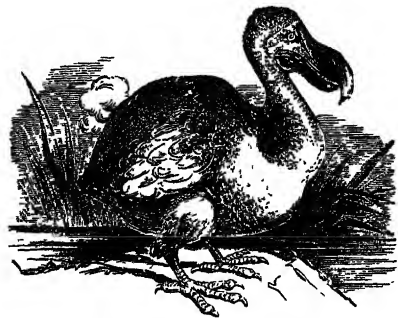

Döderlein, LUDWIG, philologist, born at Jena, 19th December 1791, studied at Munich, Heidelberg, Erlangen, and Berlin, and in 1815 was appointed professor of Philology at the academy of Bern. In 1819 he went as second professor of Philology to Erlangen, where in 1827 he became first professor and also director of the philological seminary. He died there, 9th November 1863. His principal works were on Latin synonyms (6 vols. 1826-38), on Latin etymology (1836 and 1841), a Homeric glossary (3 vols. 1850-58), and editions of the *Iliad*, *Tacitus*, &c.

Dodgson, REV. CHARLES LUTWIDGE ('Lewis Carroll'), was born at Daresbury, near Warrington, 27th Jan. 1832, and, entering Christ Church, Oxford, graduated B.A. in 1854 with a first-class in mathematics. He was elected a student of his college, took orders in 1861, from 1855 to 1881 was

mathematical lecturer, and died 14th January 1898. He published some valuable mathematical works on Plane Trigonometry (1861), Determinants (1867), *Euclid and his Modern Rivals* (1879) *Curiosa Mathematica* (1888-93), &c. As Lewis Carroll (whom he carefully distinguished from his other self) he issued in 1865 *Alice's Adventures in Wonderland*, which, with its continuation *Through the Looking-glass* (1872), has become a nursery classic; *Phantasmagoria* (1869), *Hunting of the Snark* (1876), *Doublets* (1879), *Rhyme? and Reason?* (1883; new ed. 1897), *A Tangled Tale* (1886), *Game of Logic* (1887), and *Sylvie and Bruno* (1889-93). *Symbolic Logic* (1896), however, bore the name of Lewis Carroll. See *Life* by Collingwood (1899), Williams's *Bibliography* (1924).

Dodington, GEORGE BUBB, a 'person of importance in his day,' was born plain Bubb in 1691, the son of an Irish fortune-hunter or apothecary, and took the name Dodington in 1720, on inheriting a fine property from his uncle. Resolved 'to make some figure in the world,' he had got into parliament in 1715, and from 1722 to 1754 sat for Bridgwater. Otherwise, he was always changing his place, from Walpole's service to the Prince of Wales's, from his to Argyll's, anon back to the Prince's, and so on: his one good action, that he spoke up for Byng. He was sometimes in office, but oftener out of it; and he had not long reached the goal of his ambition, a peerage with the title Baron Melcombe, when he died at Hammersmith, 28th July 1762. A *soi-disant* Mæcenas, he passed for something of a wit and poet, but is best remembered through Browning's *Parleying*, and by his posthumous *Diary* (1784), that odd self-revelation of a flunkey. See a study by Lloyd Sanders (1919).

Dodo (*Didus ineptus*), a large bird which used to inhabit Mauritius, but became extinct some time after 1681. It appears to have been allied to the pigeons, was a little larger than a turkey, and incapable of flight. Our knowledge of the bird is derived from the reports of travellers, from pictures, and above all from the skeletons disintombed in 1866. It appears also to have been sometimes brought alive to Europe. The bill was large, longer than the head, and covered for half its length by soft naked skin. The end of the bill was hooked and turned downwards. The wings and the tail were rudimentary. The feathers seem to have been gray, with yellow on the wings and tail. The legs were short, thick, and scaly. It probably lived in the thick, tropical woods, and fed on vegetable materials.

Supposed figure of the Dodo.

The extermination seems to have rapidly followed the Dutch colonisation of Mauritius. 'The bird was helpless and stupid, and withal good for eating. The hungry domestic animals brought by man doubtless helped to destroy the hapless dodo. Though a conspicuous example, the dodo is by no means the only bird which has been exterminated,

in part at least, by human carelessness. The solitaire (*Pezophaps solitaria*) of Rodriguez is another well-known case.

There are rude figures of the dodo in several works of the 17th century, and in particular one, evidently superior to the rest, in Bontius (edited by Piso, 1658)—who calls the bird *Dronte* or *Dodaers*—which perfectly corresponds with the descriptions given of it, with a painting preserved in the British Museum, said to have been drawn in Holland from the living bird, and with a representation of it discovered by Professor Owen in 1838 in Savery's picture of Orpheus and the Beasts at the Hague, which he thinks 'must have been copied from a study of the living bird.' The skeleton has been partially reconstructed, and described by Professor Owen. Many bones of this extinct bird were discovered in 1865, when extensive marshes in the island were partially drained. There are bones at Paris, Copenhagen, and Haarlem. A foot of the dodo is amongst the valued treasures of the British Museum. In the Ashmolean Museum at Oxford are a head and foot; but the stuffed specimen to which these belonged was allowed to decay, and destroyed in 1755 by order of the curators.

See Strickland and Melville, *The Dodo and its Kindred* (1848); Owen in vol. vi. of *Trans. Zool. Soc.*; and L. W. Rothschild's *Extinct Birds* (1907).

Dodona, the seat of the oldest Greek oracle, was situated in Epirus, in one of the wildest districts south-west of the Lake of Janina. The Greek and Egyptian accounts of its origin differ. The priests of Egyptian Thebes related that two holy women were carried off from that city by a party of Phœnicians, one of whom was sold in Libya, the other to the Greeks, and that these women founded the oracles at Dodona and Ammon. The inhabitants of Dodona related that two black doves took their flight from the city of Thebes, in Egypt, one of which flew to Libya, the other to Dodona; that the latter perched upon an oak, and with a human voice commanded that an oracle should be founded on the spot. Herodotus thought that if the Phœnicians did actually carry off the two women already alluded to, one of them was probably sold into Greece; that the strange language and dark complexion had caused them to be likened to birds; and that when they became acquainted with the Greek tongue, they were said to have spoken with a human voice. Later authors ascribe the founding of the city to Deucalion. The sanctuary itself was dedicated to Zeus, who made known his will by the wind rustling through the boughs of a grove of lofty oaks or beech trees. This was interpreted by the priests, who were termed *Selloi* or *Helloi*. The goddess Dione, by some said to be Aphrodite, by others Hera, afterwards appeared by the side of Zeus, and the place of the priests was occupied by priestesses (*Peleiades*), who announced the will of the deity. Dodona, though not equal in renown to Delphi, was yet frequently consulted on occasions of importance both by the Spartans and Athenians. Though the city was destroyed in 219 B.C. by the Ætolians, it recovered at a later period, and was in existence in the 6th century A.D. See *Dodone et ses Ruines*, by Carapanos (1878).

Dodsley, ROBERT, author and publisher, was born in 1703 near Mansfield, in Nottinghamshire. His father, who was a schoolmaster, apprenticed him to a stocking-weaver; but the boy was so ill-treated that he ran away, and was afterwards engaged as footman. His leisure he gave to reading, and at length published in 1732 a volume of poems, entitled *A Muse in Livery*, which was patronised by many fashionable ladies. His next production, *The Toy Shop*, a dramatic piece, was submitted in

manuscript to Pope, who undertook to recommend it to Rich, the manager of Covent Garden Theatre, under whose management it was acted in 1735 with great success. With his profits, and the interest of Pope, who helped him with £100, Dodsley now commenced business as a bookseller, and was very successful, but still continued to write bright and successful plays, as *The King and the Miller of Mansfield* (1737), *Sir John Cockle at Court* (1738), *The Blind Beggar of Bethnal Green* (1741), and *Rex et Pontifex* (1745), which were republished in a collected edition of his dramatic works with the title of *Trifles* (1748). Meantime, he was conducting his business with such ability and spirit, that in the course of three years after commencement, he was in a position to buy copyrights. In 1738 he bought *London* from the yet unknown Johnson for ten guineas, and among the other famous authors for whom he published were Pope, Young, Akenside, Lord Chesterfield, Horace Walpole, Goldsmith, and Shenstone. Among his schemes were *The Museum* (1742-47), a collection of historical and social essays; *The Preceptor*, a book of instruction for the young; and the *Annual Register*, started in 1759, and long edited by Burke. Dodsley's most successful work was a tragedy called *Cleone* (1758), which was acted at Covent Garden with extraordinary success. With *Cleone* he closed his career of dramatic authorship. Dodsley's name is now chiefly remembered on account of his *Select Collection of Old Plays* (12 vols. 1744; 2d ed. by Isaac Reed, 12 vols. 1780; 3d. ed. by J. P. Collier, 13 vols. 1825-28; 4th ed. by W. C. Hazlitt, 15 vols. 1874-76); and his *Collection of Poems by Several Hands* (3 vols. 1748; 6 vols. 1758). Dodsley died on a visit to Spence at Durham, 25th December 1764. He was not only an honest and able, but an amiable man. See Knight's *Shadows of the Old Booksellers* (1865), Austin Dobson's *Eighteenth Century Vignettes* (2d series, 1894), and R. Straus's *Robert Dodsley* (1910).

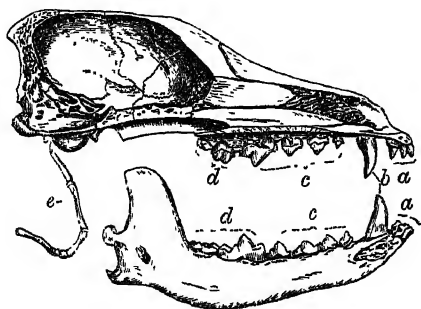

Doe, a female Deer (q. v.), in contrast to buck.

Doe, JOHN, in Law, the fictitious plaintiff in ejectment, whose services (like those of Richard Roe, his opponent) are dispensed with since the abolition of the fiction. See EJECTMENT.

Doesborgh (*Drususburg*), a fortified town in the Netherlands, province of Gelderland, at the confluence of the Old and New Yssel; pop. 5000.

Dog, the popular name of the *Canis familiaris* of Linnæus, as well as of several more or less closely allied forms. The word is not co-extensive with any zoological term, but all the animals to which it is applied belong to the family Canidæ (q. v.), which may be defined as digitigrade carnivora, with small head, pointed muzzle, somewhat contracted neck, slightly compressed body, and slender legs; forefeet bearing five, hinder four toes, claws not retractile, hair thick, tongue smooth, anal glands wanting, a gland often present at the root of the tail. The teeth usually consist of three incisors, one canine, and four premolars (teeth which are preceded by temporary or milk molars) in each jaw. The upper jaw has two, the lower three molars on each side. The last premolar of the upper jaw, and the first molar of the lower jaw are decidedly larger than any of the others, and bite against one another; they are known as the 'carnassials.' The distribution of the Canidæ is universal; many are nocturnal or semi-nocturnal; they run swiftly and persistently, swim well, and climb and leap, though not so well as the cats. Their senses are acute, especially that of smell, and they possess higher mental qualities than those of any other animal. They frequently combine to procure food, and live on other mammals and birds, devouring fresh meat or carrion with equal avidity; some

kinds will also eat reptiles, fish, crabs, insects, and various kinds of vegetable matter. The period of gestation is sixty-three days; usually from four to eight (occasionally as many as twenty) pups are produced at a birth. These are blind for ten or twelve days, and are tended with the greatest

Section of Skull of Dog :

a, incisor teeth; b, canines; c, premolars; d, molars; e, hyoid bone.

solicitude by the mother, though the father is sometimes inimical to them. Full growth is attained in about two years, the average term of life being ten or twelve, and very rarely more than twenty years. The oldest fossil form is *Canis parisiensis*, from the upper Eocene period. The creatures thus characterised are separable into three categories: (i.) Wolves (genus *Canis*), characterised by the round pupil of the eye and the tail having dependent hairs. (ii.) Foxes (genus *Vulpes*), characterised by a slit-like pupil and a bushy tail. Certain minor, but constant, differences in the skull have been pointed out by Huxley. (iii.) The Eared-fox (genus *Otocyon* or *Megalotis*).

I. The category of wolves (*Canis*) comprises (1) The Domestic Dog (*C. familiaris*), which is, to quote the perhaps extravagant words of Cuvier, 'the most complete, the most singular, and the most useful conquest ever made by man.' The origin of this subjugation is shrouded in immemorial antiquity. Almost the earliest human beings of whom we have any record seem to have been accompanied by dogs, which were apparently the first animals domesticated. In the Danish kitchen-middens belonging to the Neolithic period, canine remains accompany those of man. The birds' bones are those of the legs and wings, which dogs cannot eat, and hence it seems likely that the men, after eating the flesh of the birds, gave their remains to the dogs, who devoured what they could. This has led to the further conjecture that these dogs were domesticated. A similar form of dog has been recorded from deposits of the same age in Switzerland. In the bronze age traces of a larger dog appear. The Egyptian monuments of about 3000 B.C. furnish us with pictures of several varieties of domestic dogs—a wolf-dog, a hound, a greyhound, and a kind of terrier. 'The most ancient dog represented on the Egyptian monuments is one of the most singular; it resembles a greyhound, but has long pointed ears and a short curled tail; a closely allied variety exists in Northern Africa, as the Arab boarhound.'

Assyrian sculptures depict two canine forms, a greyhound and a mastiff, described as 'the chained-up, mouth-opening dog' (watch-dog), and several other kinds are alluded to in the cuneiform inscriptions. The first mention of the dog in the Bible occurs in connection with the sojourn of the Israelites in Egypt, and the earliest allusion to it

as the companion of man is in the Book of Tobit. The detestation with which the Hebrews regarded the dog was possibly due to its being an object of adoration to the Egyptians. Xenophon records two species of Spartan dogs. Many references are found to their use in battle, for which purpose they were sometimes provided with spiked collars, so that the 'dogs of war' was no mere figure of speech. At Marathon, one of these four-footed warriors gave such assistance to its master, that its effigy was engraved upon his tablet. Among the Romans, we have evidence of their use for many purposes, and their study had so far advanced, that a classification of them was drawn up. Three main divisions are recognised: (1) *Canes villatici* (watch-dogs); (2) *C. pastorales* (sheep-dogs); (3) *C. venatici* (hunting-dogs); which were again subdivided into *pugnaces*, to attack the quarry; *nare sagaces*, to track it out; and *pedibus celeres*, to overtake it. Between the Roman period and the middle ages materials for the history of the dog are scanty, but from this time onwards there is an extensive literature of the subject, more especially in regard to those kinds which were used in various forms of sport.

Dogs still play an important part in folklore everywhere, whether as *revenants* whose intention is merely to warn or foretell, or as hell-hounds of purely malignant nature. They are represented as quick to detect the presence of invisible spirits, and, in connection with this aptitude for seeing into the spirit-world, they are often the outward objects through which devils and demons make their appearance, and they have often been associated with such masters of unhallowed arts as the great Cornelius Agrippa. The Wild Huntsman with his train of hounds is one of the most widespread superstitions in Europe, and in the dim mythological histories of the early world we find many dogs of supernatural strength and courage who give material aid to the heroes in their exploits. Such are Fingal's companions, Bran and Luath, the Gelert of the Welsh story, Arthur's hound Cavall, and Hodain, the hound linked so strangely with the fates of Tristrem and Ysolde. St Eustace was the patron of dogs in the south of Europe, as St Hubert was in the north, and the invocation of the latter was especially efficacious in cases of hydrophobia (see Gaidoz, *La Rage et St Hubert*, 1887). In Egypt, where in ancient times the dog was a sacred animal, his name is the most insulting term of reproach at the present day; yet by some Orientals, as the Parsees, he is held in strange respect; while Kitmer, the dog of the Seven Sleepers, with Balaam's ass and the camel that bore Mohammed in his flight from Mecca, have a place in the Moslem paradise. From the old Argus that first recognised his master in the *Odyssey* down to Pope's Bounce and the Maida of Sir Walter Scott, dogs have been celebrated in the history of letters, and have been depicted in art, by none more admirably than by Velázquez, Veronese, and Landseer. Among famous historical dogs may merely be mentioned the mastiffs of the Knights of Rhodes, who knew a Turk from a Christian by the smell, the Spanish bloodhounds who helped in the conquest of Mexico and Peru, and the spaniel which saved the Dutch republic by waking William the Silent during the night attack on the camp before Mons. Punch's dog Toby, and the famous dog of Montargis that avenged his master's death upon his murderer, are among the best-known animals of Europe. See 'The Dog in History and Folklore' in R. J. King's *Sketches and Studies, Descriptive and Historical* (1874).

The question of the origin of our various domestic dogs may now be considered. Buffon supposed that the sheep-dog was their progenitor; Bell, the

wolf. Neither of these earlier views, however, takes a sufficiently wide survey of the whole subject to be worthy of much consideration. Put very briefly, the principal facts which help us to the solution of this problem are the following: The different breeds are very unlike each other, which would suggest the likelihood, though it would not prove, that they were descended from different ancestors. This variety of breeds obtains even in the earliest domestic dogs of which we have any record. There is no difficulty in imagining that various races of men have domesticated dogs in different places and at different periods. Wild canine species are scattered over the whole world; they are social animals, hunting in packs, and such are most easily tamed. When first in contact with man, too, animals are not as a rule shy. Savages are known to value dogs highly, and it has been suggested that perhaps the sight of their combined pursuit of their prey may have given man the idea of employing them. Furthermore, the dogs of semi-civilised or barbarous peoples often present a very close resemblance to the wild forms surrounding them; thus, the Indian dogs of North America so closely resemble the wolves of that region, that they have been mistaken for them even by well-trained naturalists. The Eskimo dogs are very like the gray Arctic wolves, with which their owners not unfrequently cross them to improve the breed. The dog of the Hare Indians differs but very slightly from the prairie-wolf or coyote (*C. latrans*). The natives of Guiana seem to have partially domesticated two aboriginal forms. Many European varieties approximate closely to the wolf, as, for instance, the Hungarian sheep-dog. The Indian pariah dogs are but little removed from the native wolf, whilst some other breeds show a close affinity to the jackals. These latter, when tamed, wag their tails, crouch to their masters, and behave in other respects like domestic dogs. From these statements, and many others which might be added, it seems fair to conclude that the various domesticated canine forms have arisen from the following separate sources: two well-defined species of wolf (*C. lupus* and *C. latrans*); certain doubtful species, European, Indian, and North African, from several species of jackal, and perhaps also from some extinct forms.

It must not, however, be supposed that the differences between the various breeds are entirely due to this difference of parentage, for there can be no doubt that they are largely the effect of careful breeding and selection. Variations occur in almost every part of the animal's organisation. As regards size some are six times as long as others (the tail being excluded); the ratio of the height to the length varies from 1 : 2 to 1 : 4. The number of caudal vertebrae, the number of teats, and the number and disposition of the teeth, are all subject to modifications. Among peculiarities which are confined to domestic as opposed to wild dogs may be mentioned the drooping ears and the curled up tail; the former correlated with a diminished need for watchfulness; the latter with a decreased use of the tail as a helm. Barking, too, is almost universal in domestic breeds, but does not characterise a single wild form. Certain tame dogs, which were left on the island of Juan Fernández, were found after thirty years to have quite lost the faculty, and only gradually reacquired it on renewed contact with man.

No account of the domestic dog would be complete without an allusion to his mental qualities, which lift him high above all other animals, and pre-eminently fit him to be the companion of man. Anecdotes illustrative of his keenness of sense, reasoning faculties, fidelity, and conscientiousness,

might be multiplied indefinitely. For these we may refer our readers to the pages of Jesse, Walsh ('Stonehenge'), and Gordon Stables; for their scientific treatment, to the works of Darwin, Awebury, and Romanes. See also INSTINCT.

The natural qualities of the dog enable him to be of service to man chiefly in the chase, but he has been utilised also (to say nothing of his consumption by the Chinese and certain barbarians as food) as a guardian and a guide, as a saviour of life from drowning, and a beast of draught; he has ministered to a depraved curiosity in the ancient sports of bull and bear baiting, and has even acted as an instrument of torture and as a minister of justice. Dog-farming is regularly pursued in Manchuria for the sake of the skins, the breed cultivated being remarkable for the length and fine quality of the hair. There are thousands of such dog-farms, keeping from a score to several hundreds of dogs. The dogs are strangled in mid-winter, that the furs may be got in the best condition, but they must be at least eight months old.

(2) The Wolf (*Canis lupus*) will be considered in a special article.

(3) The Indian Wild Dogs (*C. dukhunensis*, *C. primevus*, *C. rutilans*) are sometimes separated as a distinct genus (*Cuon*). They occur in different parts of India, and are variously known as Kolsun, Buansuh, or Dhole. They are generally reddish-brown in colour, with a moderately long tail, full below, not a round brush like the fox; the pupil is round, and the ears erect, large, and hairy. They hunt in packs of from six to thirty, with such keen scent and pertinacity that competent observers declare that, 'when once a pack of them put up any animal, no matter whether deer or tiger, that animal's doom is sealed; they never leave it.' Certain half-domesticated individuals are employed for coursing and pig-sticking.

(4) The Australian Wild Dog or Dingo (*Canis dingo*) is particularly interesting, as being the only higher mammal found in that country. It was formerly believed that it was sprung from some domestic form which had run wild, but this opinion is now abandoned owing, amongst other reasons, to the discovery of fossil dingoes in the diluvial deposits. It resembles the larger varieties of shepherds' dogs. The forehead is flat, and the ears short and erect. The body has two kinds of hair, silky and woolly. When running, the head is carried high and the tail horizontally. The earliest settlers in Tasmania suffered much from the loss of their sheep owing to these animals; now the dingoes are almost destroyed. They are sometimes domesticated by the aborigines, who, however, never capture the adults, but secure a litter of pups, which they bring up by hand. They are easily tamed, but almost invariably run wild again when the breeding season comes on. See DINGO.

(5) The Jackals (*Canis anthus*, *C. aureus*, &c.). See JACKAL.

(6) The Pariah Dogs form a nondescript breed of animals, which inhabit the towns and villages of the East, where they act as general scavengers. They associate in bands, each of which has its own allotted territory, beyond whose bounds no member dares to pass.

(7) The Raccoon Dog (*Canis procyonoides*) is so called because it presents a superficial likeness to the raccoon. It is, however, a true dog, and it is more than doubtful whether the generic name (*Nyctereutes*) proposed for it should be allowed to stand. The body is arched, the legs short and slender, the tail also short but bushy. It is found in Japan and Northern China.

(8) The Hyæna Dog (*Canis* or *Lycan pictus*) occurs in South Africa. It is about the size of a

wolf, with blunt muzzle and sloping back. There are only four toes on each foot. Its colour varies greatly, consisting of very irregular patches of black, white, and yellow. It is partly diurnal, partly nocturnal. Large packs of these animals hunt together, and run with an untiring gallop which will overtake the swiftest antelope. They have three different calls, the most curious of which is a soft and melodious cry, something like the second note of the cuckoo, and appears to serve as a rallying note for the pack.

II. The Foxes (genus *Vulpes*) will be the subject of a special article (q.v.)

III. The Long-eared Fox (*Otocyon* or *Megalotis lalandii*) is also a native of South Africa. It has a short bushy tail, not more than half the length of the body and head, which measure about two feet. The ears are very large, and the snout short and pointed. It has six more teeth than most of the Canidæ, two in each upper and one in each lower jaw.

Law as to Dogs.—In Britain, dogs cannot be kept without a license, which, for each dog, costs 7s. 6d. Dogs not six months old, dogs for tending sheep and cattle, and dogs for guiding blind men are exempt. Certificates of exemption may be obtained from the Commissioners of Inland Revenue. At common law a dog is entitled to its first bite; that is, the owner is not liable for its attacking a person or animal, unless he knew of its propensity. But by the Dogs Act, 1906, this defence is not open in case of injury done to cattle, horses, &c. A dangerous dog may be destroyed by order of court. Dog stealing; having stolen dogs, or the skins of stolen dogs, in one's possession in the knowledge that they are stolen; taking money to restore a stolen dog under pretence of aiding the owner to recover it; and unlawfully and maliciously killing or wounding or maiming dogs, are offences under various criminal statutes, and are punishable summarily, and by indictment for misdemeanour. A gamekeeper may seize a dog within the limits of a manor, but is not allowed to kill a dog there following game, even although its owner has received notice that trespassing dogs will be shot; and a man is liable in damages if he places on his land traps scented with strong-smelling bait, so as to influence the instinct of another man's dogs, and draw them irresistibly to destruction. Stay dogs may be detained and sold or destroyed by the police. For the employment of dogs to draw carriages or carts, see ANIMALS (CRUELTY TO).

In the United States, the statutory regulations of most States empower a person to have property in a dog, not only sufficient for the owner to be indemnified for injury done to the dog, but also to make theft of the dog liable to punishment as a crime. Some States require that the dog shall be duly licensed or registered and collared, and therefore subject to taxation, before these results follow. Unless duly authorised by law to kill unlicensed dogs, no citizen may kill a dog belonging to another, unless he, or some one under his protection, or his animal, is in immediate danger of injury from the dog, or the dog is rabid, or has been bitten by a rabid animal. In general, the owner of a dog is liable in damages for injuries done by his dog; but the master can plead ignorance of the vicious habits of the dog as a complete defence, except where it has been expressly excluded by statute, as is the case in some States. The owner of a vicious dog may be indicted for keeping a nuisance, and compelled to kill or muzzle his dog. Dog-racing is not illegal when for training purposes only, but if chance is the principal element, it becomes a crime within the statutes against gaming.

In some countries it is usual to compel the dogs

living in towns to be muzzled; the civic authorities in Britain sometimes, and in the United States generally, issue edicts that all dogs be kept muzzled for a certain number of weeks, and occasionally the police make raids on ownerless dogs and destroy them. It is now not unusual to have homes maintained for stray dogs, the least valuable of the unclaimed ones being ultimately destroyed.

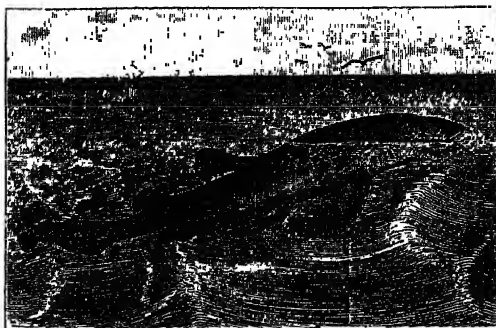

For the various breeds of dogs, see BEAGLE, BLOOD-HOUND, BULLDOG, COLLIE, GREYHOUND, MASTIFF, NEW-FOUNDLAND DOG, TERRIER, &c. For the diseases of the dog, see DISTEMPER, MANGE, RABIES. See also COURISING, FOX-HUNTING, STAG, &c.

Dogbane (*Apocynum*), a small north temperate genus of Apocynaceæ, perennial herbs or undershrubs. The Dogbane of North America (*A. androsaemifolium*), often called Fly-trap, from the throat appendages of its corolla closing upon the flies which enter it, is of medicinal repute; similarly also its congener *A. cannabinum*, or Canadian Hemp, which yields a fine fibre. See APOCYNACEÆ.

Dog-days (*Dies Caniculares*) is a name given by the ancient astronomers to the 20 days before and 20 days after the rising of the *Dog-star* or Sirius (q.v.), at present reckoned from 3d July to 11th August. It is a mere accident that the rising of Sirius falls in the hottest season of the northern year; in time it will be in the dead of winter. But the ancients attributed the heat and the accompanying diseases directly to the influence of the star—as also in Egypt the highest rising of the Nile.

Doge (the Venetian form of the late Lat. *dux*, *docis*, equivalent to *dux*, 'leader,' 'duke') was the name of the chief-magistrate, possessing princely rank, in the republics of Venice and Genoa. For the history of the office and its powers, see GENOA, VENICE; also BUCCENTAURE.

Dog-fish, the popular name for a number of cartilaginous (Elasmobranch) fishes in the shark sub-order. They belong to the genera *Scyllium*, *Pristiurus*, *Acanthias*, &c., and have the general characters noted under Cartilaginous Fishes (q.v.). (1) The 'rough hound,' or Lesser Spotted Dog-fish (*Scyllium canicula*), is common off European coasts, feeding chiefly among rocks at the bottom. It measures from 16 inches to over 2 feet in length; is reddish-gray, with brown spots

Lesser Spotted Dog-fish (*Scyllium canicula*).

above, and dirty yellow below. The eggs, which in the oviparous dog-fishes are large and few in number, are inclosed in pale yellow, horny purses, with long mooring tendrils, and are laid throughout summer and autumn. These envelopes are known as mermaids' purses, sailors' purses, or sea purses. The animals are sometimes cooked for soup, and their flesh even may be eaten. (2) The 'nurse hound,' or Larger Spotted Dog-fish (*S. stellare*

or *catulus*), is a larger species, 3 to 4 feet in length, of a reddish-gray colour, with large, round, brown spots. The eggs are laid late in the year. The flesh is too coarse to be edible. The skin of both spotted dog-fishes is studded with tubercles of dentine capped with enamel, and when prepared is used as 'rubskin' for polishing. (3) The Black-mouthed Dog-fish (*Pristiurus melanostomus*) measures a little over 2 feet, and is of a brownish-yellow colour above, and paler below. The dark spots are large, oblong, and disposed in two rows. The snout is longer, and there is a row of small spines on each side of the upper margin of the tail. (4) The Picked Dog-fish (*Acanthias vulgaris*), belonging to a different family (Spinacidae), is more abundant off British coasts than any of the others. It measures about 3 feet in length, and is a voracious, prolific, hardy animal. It is not oviparous, and is said to produce young almost daily for eight or nine months a year. Its skin is not so rough as that of the spotted dog-fishes. The colour is slaty-gray or reddish-brown above, and whitish beneath. The two dorsal fins are each provided with a strong spine, which the fish uses with great accuracy as weapons. It gets a variety of names, such as bony dog, hoe, &c., and is much and justly hated by the fishermen for the damage it does to nets and lines, and for the voracity with which it attacks the shoals of herring and other food fishes. The names 'dog,' 'hound,' &c. are characteristic of all the set, but are particularly applicable to *Acanthias*. As many as 20,000 have been caught at a time, and their consequent destructiveness can be readily imagined. The young are born alive, two at a time, but in very rapid succession for prolonged periods. The flesh, though coarse, is sometimes eaten; and the eggs are said to be appreciated. The livers yield oil. To numerous related genera of wide distribution—e.g. *Centrophorus*, *Spinax*, *Scymnus*, the title dog-fish might also be applied. See CARTILAGINOUS FISHES, SHARK.

Dogger (Dutch *dogger-boot*, 'codfish-boat'), a vessel something like a galliot or a ketch, used by the Dutch as a fishing-boat in the German Ocean.

Doggerbank, an extensive flat sandbank in the North Sea, between England and Denmark, about 100 miles off the Yorkshire coast. It is about 170 miles long by 65 broad, with an average depth of from 8 to 16 fathoms. Its fisheries are valuable (see FISHERIES). The bank saw in 1781 an indecisive fight between the Dutch and English fleets. The 'incident' caused by the attack on Hull fishing-boats off the Doggerbank by the unfortunate Russian fleet on its way to Japanese waters in October 1904 was brought to an end by a Commission in February 1905. For the battle of 1915, see TACTICS, WAR (GREAT).

Doggett, THOMAS, a capable English actor who died in 1721, but is chiefly kept in remembrance as the founder of a prize—'Doggett's Coat and Badge,' still annually competed for by watermen at a sculling-match on the Thames on the 1st August. The original bequest, made in 1716 in honour of the accession of George I., has been supplemented from other quarters. See a book by Cook and Nickalls (1908).

Dog-grass. See COUCH-GRASS.

Dogma. There is the utmost diversity of opinion among theologians as to the exact meaning of the term 'dogma' and the relation between dogma and doctrine. The majority of writers seem to regard doctrine as a simpler form of dogma—a belief which has not yet been finally adopted and authenticated as a fundamental article of faith. In other words, doctrine is dogma in the making. Writers, moreover, are not agreed as to what it is that lifts

doctrine into dogma. Many hold that a dogma is a doctrine which has received the sanction of some church council or ecclesiastical court, or which has been accepted by some Christian community as a test of membership. Others maintain that it is a doctrine which has been expounded in philosophical or metaphysical terms before its acceptance by some duly constituted authority. Harnack, for instance, says the distinguishing element in dogma is the result of the intrusion of Greek ideas into the Christian Church, and McTaggart asserts that some metaphysical idea is involved in every dogma. In contrast to these theories Dr Forsyth has recently developed a quite different view. He maintains that dogma represents the fundamental principles—the basic truths—of Christianity stated in their simplest form, and that doctrine is always an explication and elaboration of dogma.

These different interpretations of the term may be easily explained from its history. (1) The term 'dogma' is a Greek word which originally meant 'that which has been approved or decided.' In medical circles it was used to denote the scientific method of treatment as opposed to quackery and empiricism. In philosophical circles—among the Stoics, for instance—it was used to describe the fundamental axiomatic principles which form the data of all true thinking. In the legal sphere it was applied to provisions and enactments which had duly received the sanction of the court or legislative assembly. It occurs in the last sense several times in the New Testament, e.g. of the decisions of the Council of Jerusalem (Acts, xvi. 4), of the enactments of the Jewish law (Col. ii. 14; Eph. ii. 15), of the decrees of emperors (Luke, ii. 1; Acts, xvii. 7). There is no instance in the New Testament of the word being used to denote Christian beliefs or doctrines, since the passages already cited in Colossians and Ephesians cannot possibly bear that meaning.

(2) Different meanings were assigned to the word at different stages in the development of Christian theology. What was a dogma, for instance, in the 1st and 2nd centuries, was not a dogma in the 4th and 5th, and the character of dogma was altogether revolutionised by the Reformation. We may briefly indicate the different stages as follows:

(a) In the first stage, which we may roughly identify with the period 100–300 A.D., the term dogma was undoubtedly used to denote the universally admitted principles and truths which formed the basis of Christianity. 'Take pains to be established in the dogmas of the Lord and his Apostles,' writes Ignatius to the Magnesians, and he is not thinking of any theological doctrine, but rather of the ethical principles and rules of conduct which Jesus laid down for the guidance of his followers. The earliest dogmas were therefore ethical precepts and laws of conduct, and simple statements of Christian belief. As time went on, however, in view of Gnostic and other heretical movement, it became necessary to formulate the Christian position. The first attempt at creed-making is found in the outline of belief, which was drawn up at Rome probably about 140 A.D., and which afterwards formed the basis of the Apostles' Creed.

(b) It was in the second period (from 300 to 700) that the great change came over the conception of dogma. The Arian and the Christological controversies of the 4th and 5th centuries compelled the Church to define its belief upon the points in question. In the search for these definitions the Church was bound to go beyond the statements of the New Testament, and adopt philosophical terminology. The decisions which were reached by the oecumenical councils of Nicea and Chalcedon were subsequently regarded as tests of orthodoxy, and from this point onward dogma came to signify

the theological interpretation of the Christian facts rather than the facts themselves. The authority upon which dogma rested was at this stage the decision of the oecumenical council, and it could be claimed that each dogma had received the sanction of the whole Church.

(3) The third period (700-1500) is marked by the cleavage between the eastern and western divisions of Christendom, which resulted nominally from a difference of opinion on the doctrine of the Procession of the Holy Spirit. Henceforth the Church spoke with two voices, and it was obviously impossible to establish any new dogma which had the authority of a united Christendom behind it.

(4) The Reformation resulted in still further divisions in the western Church, and a radical separation between Protestantism and Roman Catholicism on many points of doctrine, as may be seen from a comparison between the Creed of the Council of Trent and the Augsburg Confession. After the Reformation it became more impossible than ever to secure the sanction of the whole Church for any dogma. If this consent is a necessary condition, we are bound to agree with Harnack that the history of dogma ends at the Reformation. As a matter of fact, if we press the condition at all absolutely, no new dogma was possible after the separation of the eastern and western churches. Henceforward we find a large number of different confessions of faith, which we may regard as embodying the dogmas of different sections of the Church. Sometimes these dogmas were expressed in the form of articles of belief, e.g. the Thirty-nine Articles of the Anglican Church—sometimes in books which were regarded as authoritative by particular churches. The Roman Catholic position was expounded, for instance, in Bellarmine's *Disputationes*, the Lutheran in Melancthon's *Loci Communes*, the Reformed in Calvin's *Institutes*, the Methodist in Wesley's *Journal and Sermons*. It should be stated that all these churches accept the authority of the creeds which were drawn up by the undivided Church in the 4th and 5th centuries. They differ, however, on many other dogmas, e.g. predestination, the doctrine of grace, the interpretation of the sacraments, &c.

See CREED, and the Histories of doctrine by Harnack, Hagenbach, Shedd, G. P. Fisher, Thomasius; McTaggart, *Some Dogmas of Religion* (1906); Kaftan, *Glaube und Dogma* (1889); Dorner, *System of Christian Doctrine*; W. N. Clarke, *Outline of Christian Theology*; W. Adams Browne, *Christian Theology in Outline*; and P. T. Forsyth, *Theology in Church and State* (1915).

Dogberry. See DOGWOOD.

Dogrose. See ROSE.

Dogs. See ANDIRON.

Dogs, ISLE OF, a district of London, metropolitan borough of Poplar, formed by a sudden bend in the Thames opposite Greenwich. It contains the West India and Millwall docks. Royal kennels are said to have been formerly situated here, but this, and the derivation from 'dogs' as a corruption of 'docks,' are equally unsatisfactory.

Dogskin, used for Gloves (q.v.), may be the skin of the dog, or sheepskin specially prepared to resemble it.

Dog's Mercury. See MERCURY.

Dog's Parsley. See FOOL'S PARSLEY.

Dog's-tail Grass (*Cynosurus*), a small genus of meadow grasses, of which *C. cristatus* is esteemed for pastures and lawns. See GRASSES, PASTURE.

Dog-star. See SIRIUS.

Dog's-tongue. See HOUND'S TONGUE.

Dog's-tooth Grass. See CYNODON.

Dog-tooth, in Architecture, an ornament or moulding used from late Norman to early Decorated. See TOOTH-ORNAMENT.

Dog-tooth Spar. See CALCITE.

Dog-tooth Violet (*Erythronium dens-canis*). See ERYTHRONIUM.

Dog-whelk. See WHELK.

Dogwood, or DOGBERRY, the name usually given to some of the trees and shrubs of the genus *Cornus* (see CORNELL, CORNACEÆ). The Common Dogwood of Europe (*C. sanguinea*) is a shrub of

Common Dogwood (*Cornus sanguinea*):
a, flower.

remarkable beauty in autumn from the deep redness of its foliage. The wood makes the very best charcoal for gunpowder. It is very hard, and is made into skewers, cogs for wheels, &c., and in former times it was in request for making arrows. The small bitter fruit yields as much as one-third of its weight of an oil resembling that of olive. The wood of *Rhamnus frangula*, the berry-bearing alder, is also used by gunpowder makers, and called by them dogwood.—The Dogwood of North America (*C. florida*) is a very ornamental little tree with whitish flowers, surrounded by large white bracts, which appear before the leaves in early spring, and scarlet berries in winter. The wood is white and fine grained, and suitable for inlaying, and the bark, like that of some allied species, is a useful febrifuge.—Jamaica Dogwood is *Piscidia erythrina*, a papilionaceous timber-tree; the cortex of the root is powerfully narcotic, used for stupefying fish or deadening the pain of toothache. See also LEPTOSPERMUM, SUMACH.

Dohnanyi, ERNST VON, composer and pianist, was born at Pressburg, 27th July 1877, studied at the Hungarian Academy of Music at Budapest, and for a short time with Eugen d'Albert. From 1897 he made tours in Europe and America, proving himself a pianist of very high accomplishment. Later he gave himself more to composition. His works, which are of real value, include chamber-music, symphonies, pianoforte pieces, and opera.

Dohrn, ANTON (1840-1909), zoologist, was born at Stettin, studied at Königsberg, Bonn, Jena, and Berlin, lectured for a time on Zoology at Jena, and in 1870 founded the great zoological station at Naples. As an embryologist, he devoted himself mainly to the development of insects and

crustaceans; and, besides reports, he published works on the origin of the vertebrates.

Doiran, a shallow circular lake of Macedonia, in Greece, bordering on Yugoslavia, drains to the Vardar. The town of Doiran stands on its south side.

Doit, a small copper coin current, though illegally, in England in the sixteenth century. It was a Dutch coin (*dunt*), in value equal to the eighth of an English penny, or half a farthing.

Dol, an antique walled town in the French department of Ille-et-Vilaine, 10 miles SE. of St Malo by rail. Its former cathedral is a striking granite building of the 13th century. To the north is the isolated Mont Dol (213 feet). Pop. 4500.

Dolabella, PUBLIUS CORNELIUS, Cicero's profligate son-in-law, was born about 70 B.C., and in 49 had to seek a refuge from his creditors in the camp of Cæsar. In the following year he obtained the tribuneship, and at once brought forward a bill, cancelling all debts, which led to bitter and bloody struggles in Rome. He accompanied Cæsar to Africa and Spain, but on his leader's death promptly usurped the consular insignia, approved of the murder, and made a great display of republican sentiments, which he professed until Antony gave him the province of Syria. At Smyrna he murdered C. Trebonius, the proconsul, in February 43, and proceeded to wring money and troops from the towns of Asia with a recklessness that speedily brought about his outlawry. Within the year, Laodicea, in which he had shut himself up, was taken by Cassius, and Dolabella, to escape his enemies, ordered one of his own soldiers to kill him, 43 B.C.

Dol'ce, an Italian term in music, meaning softly and with tenderness.

Dolci, CARLO or CARLINO, a celebrated painter of the Florentine school, was born at Florence in 1616. He received his first instructions in art from Jacopo Vignali, a pupil of Roselli, and a remarkably skilful teacher. After an uneventful life spent entirely in his native city, Dolci died January 17, 1686. His works, which consist chiefly of madonnas and saints, exhibit the character attributed to him. The faces are full of a pleasing and tender softness, which, however, is often carried so far as to rob them of all character. Dolci's drawing is generally correct, his colouring exquisitely delicate and transparent, and in the nicety and laborious care of his finish he approaches the most characteristic examples of the Dutch school. His works are numerous, and scattered over all Europe. Besides his madonnas, the most famous are his 'St Cecilia,' 'Christ Blessing the Bread and Wine,' and 'Herodias with the Head of John the Baptist,' in Dresden.

Doldrums. See WIND.

Dôle, a town in the French department of Jura, on the Doubs, 29 miles SE. of Dijon by rail. It contains a Gothic cathedral, a college, and a library; and it has quarries, foundries, manufactures of metal wares, and a trade in grain, flour, wine, and cheese. Pop. 16,000. Dôle, the birthplace of Pasteur, is the *Dola Sequanorum* of the Romans, of whom many traces remain. It was in the 15th-17th centuries a strong and oft-disputed fortress, and the capital of the Franche-Comté (q.v.), with a university and a parliament.

Dolerite. See BASALT.

Dolet, ÉTIENNE, 'the martyr of the Renaissance,' was born at Orleans, in France, in 1509. The circumstances of his birth were somewhat mysterious, and it was even asserted that he was the natural son of Francis I. But this story is rejected by all his trustworthy biographers. At the age of twelve Dolet went to the university of

Paris, where his attention was directed to the study which became the chief interest of his life—the writings of Cicero. Proceeding to Italy in 1526, he continued his studies at Padua and Venice, and after six years returned to France, settling in Toulouse. Here Dolet's troubles began. In Italy he had thoroughly imbibed the spirit of humanism, with its zeal for the study of the classics, and its indifference to the teaching of the church. As orator of the French 'nation' in the university of Toulouse, he delivered a harangue 'which laid the first fagot of the pile that consumed him.' On this occasion he was punished with three days' imprisonment. In 1534 Dolet left Toulouse for Lyons, where, under circumstances that have not been explained, he killed a person of the name of Compaing. Having received the royal pardon, he still continued to reside in Lyons, always under strong suspicion of heresy. In 1542 he received the royal permission to set up a printing-press, but soon brought himself into trouble on account of the heretical books he published. He was arrested more than once on this charge, but always succeeded in escaping the last penalty of the law. At length, in 1544, he was found guilty of heresy on a charge mainly based on an alleged mistranslation of Plato, in which he was accused of denying the immortality of the soul. After two years' imprisonment, Dolet was burned in the Place Maubert, Paris, 3d August 1546. Dolet's fate has given him an interest and importance he would not otherwise have had. At the same time, by his indefatigable industry as a writer and printer, he did valuable service to the cause of learning in the 16th century. His most important work is his *Commentaries on the Latin Language*. See Richard C. Christie's *Étienne Dolet* (1880; new ed 1889; French trans. with 'appendix bibliographique,' 1885), and O. Galtier, *Étienne Dolet* (1908).

Dolgelly, or DOLGELLEY ('dale of hazels'), the capital of Merioneth, North Wales, on the Wnion, 62 miles SW. of Chester by rail. It lies in a rich and picturesque valley, at the foot of Cader Idris, and during the summer months is much frequented by tourists. It has manufactures of coarse woollens and flannels; its Welsh tweed is in great repute. Pop. 2000. Here, in 1404, Owen Glendower held a parliament, and signed a treaty of alliance with Charles VI. of France.

Dolgoruky, KATHARINA, PRINCESS, the favourite of the Russian Tsar, Alexander II., who married her in July 1880, after the death of his first wife, Marie, and made her Princess Yurievskaja. She was born at Moscow, 2d November 1847. After the Tsar's tragical death she lived abroad, and published at Geneva in 1882, under the pseudonym of Victor Laferté, *Alexandre II., Détails inédits sur sa Vie Intime et sa Mort*. Her *Mémoires* (1890) were suppressed by the Russian government. She died at Nice, 15th February 1922.

Dolichocephalic. See SKULL.

Dolichos, a large genus of Leguminosæ, sub-order Papilionaceæ, closely allied to *Phaseolus* (see BEAN), annual or perennial. Some are cultivated on account of their edible seeds or pods, notably *D. Lablab* of India and Egypt, *D. soya* (or *Soya hispida*), the Soy-bean of China and Japan, and many others. See SOY. The Horse-gram, *D. biflorus*, is cultivated in India, &c., for horse and cattle food.

Doll, an imitation human figure used as a toy, especially by girls. The word is probably a form of *Dorothy*. The use of dolls as an assistance to the operations of the young mind dates from the most remote times, and is common in all countries, barbarous as well as civilised,

springing from the early mental process which requires some object to increase the definiteness of the child's ideas. Thus, however roughly made the doll may be, it answers a purpose—setting the child's brain to work, and enabling it, by the association of ideas, to form a mental picture of what it is intended to resemble. With many uncultured tribes the doll is not confined to children. Among the Bechuanas, married women carry a doll with them till they have a child, when it is discarded; a similar practice being observed by Basuto women. In many parts of Africa, whenever twin children are born, one of them is killed; and among the Wanyamwezi, it is usual for the mother 'to wrap a gourd or calabash in skins, to place it to sleep with, and feed it like the survivor.' Even the European child's love for the doll by no means depends on its artistic excellence; a bit of stick dressed with a few rags is often hugged as heartily as the finest toy-baby.

Roman
Ivory Doll.

As in the case of most other Toys (q.v.), dolls were at one time imported into Great Britain chiefly from the Netherlands; and hence not an unusual name for a doll was a Flanders baby. These old Flemish or Dutch dolls were made of wood, with neatly formed faces and flashy dresses, the cheaper kinds having slender wooden legs.

Dollar, a pleasant town of Clackmannanshire, at the foot of the Ochils, and near the Devon's right bank, 6 miles N.E. of Alloa, and 12 E.N.E. of Stirling. It has bleachfields, but owes its chief well-being to its academy, a domed Grecian edifice (1818-67), which, founded under the will of Captain John M'Nab (1732-1802), a Dollar herdsboy and London shipowner, gives higher and secondary education to 800 pupils of both sexes. A mile north of Dollar are the noble ruins of Castle Campbell or Castle Gloom, crowning an almost insulated knoll, amid mountain-rivulets and bosky woods, with King's Seat (2111 feet) rising behind. It belonged to the family of Argyll from 1465 till 1805, in 1556 sheltered John Knox, and in 1645 was burned by Montrose. At Dollar in 877 the Danes won a victory; and in 1538, its 'good vicar,' Thomas Forrest, was burned at Edinburgh for heresy. Pop. (1851) 1079; (1881) 2014; (1921) 1584. See Beveridge's *Between the Ochils and the Forth* (1888).

Dollar, the familiar unit of the monetary system of the United States, as well as of Canada and Bolivia, Liberia, and, under the name of peso, or Mexico and Uruguay. The name *dollar* is a variant of the German *thaler* and Danish *daler*. The name arose about the year 1600 in Germany. The Counts of Schlick were then coining ounce-pieces from silver obtained in their mines at Joachimsthal (Joachim's Dale) in Bohemia, which gained such high repute as to become standard coins; whence the name *Joachims-thaler*, which finally, for shortness, took the form of *thaler*—literally, a 'valley-piece.' The name was soon extended to other coins of similar size—notably to the old Spanish 'piece of eight,' the *peso* of eight reals. From 1873 to 1878 the gold dollar was the sole standard of value in the United States. This coin contains 25·8 grains of gold of the United States standard of fineness—namely $\frac{9}{10}$ pure gold; the British standard being $\frac{11}{12}$ pure gold. The gold dollar is thus worth about 4s. 2d. sterling. In 1878 the United States government remonetised silver, since which time the United States have

had a double standard. The standard silver dollar contains 412½ grains troy of silver, of which $\frac{1}{10}$ is alloy. The silver dollar (like a paper dollar) is exchangeable anywhere in the United States for a gold dollar; although the bullion value of the silver it contains was, prior to 1919, considerably less. It varies, in fact, with the market price of silver. The dollar is divided into 100 cents; there are silver half and quarter dollars, and dimes (ten cents), nickel half-dimes, and copper cents, the coins of least value in the United States currency. The U.S. trade-dollar of 420 grains had ceased to be a legal tender, but till 1883 was specially coined for export to China and other Asiatic regions. It is very nearly equivalent in intrinsic value to the Mexican dollar, so long recognised as the standard of values in the Chinese trade. The British at Hong-kong and the Japanese government coin trade-dollars also. The Canadian dollar is about equivalent in value to that of the United States. Among other coins that are, or may be, called dollars from their approximation in value to the United States standards, are the *boliviano* of Bolivia (silver, about 72 cents); the *peso* of Spain (97 cents), of Chile (78 cents), of Cuba (92 cents), of the Central American Republics, and of Colombia (80 cents); the *sucre* of Ecuador (72 cents); the *gourde* of Haiti (80 cents); the *yen* of Japan (gold, one dollar; silver, 80 cents); the dollar of Liberia (worth one American dollar); the Mexican *peso* (75 cents); and the *sol* of Peru (80 cents); all of them of silver, except when otherwise stated. The *thaler*, equalling 3 marks, or 71 cents, till 1875 formed the standard of value of almost all northern Germany. The double florin of Great Britain (first struck in 1887) has a value of 4s., and is approximately a dollar.—The derivation of the *dollar* mark (\$) has been variously ascribed to (1) a combination of the initials U.S.; (2) a modification of the figure 8, a piece of eight being formerly indicated by the character 8-S; (3) a form of HS., which marked the Roman unit; (4) the contraction of P and S employed in Spanish accounts to indicate *peso*; (5) a device formerly seen on the reverse of the Spanish dollar, and again, since 1848, on the *peso duro*, representing the Pillars of Hercules, and round each a scroll displaying the inscription *Plus ultra*.

Dollart, THE, a gulf of the German Ocean, at the mouth of the river Ems, between Hanover and Holland. It is 8 miles long by 7 broad, and was formed by inundations of the sea (1277-1362), which submerged 50 villages and several towns. Of late years much territory, especially on the flat German coast, has been won back from the sea.

Dolling, ROBERT WILLIAM RADCLIFFE (1853-1902), destined as 'Father Dolling' to secure love and enormous influence as a social reformer in the slums of Landport and Poplar, was the son of a landlord at Magheralin, in County Down, and was educated at Harrow and Trinity College, Cambridge. He settled in London in 1878, was ordained in 1883, and was closely associated with Father Hanlon, A.H. Mackonochie, and the militant ritualists. In his charges at Southwark, Portsmouth, and Poplar he showed the same magnetic power with reputable and disreputables, the same evangelical fervour combined with advanced ritualism and radical politics, and the same impatience of ecclesiastical authority. See *Lives* by Osborne (1903) and Clayton (1902).

Döllinger, JOHANN JOSEPH IGNAZ, one of the most scholarly and eminent of recent German Catholic theologians, was born at Bamberg on 28th February 1799. After teaching for three years in the Lyceum at Aschaffenburg, he was appointed (1826) professor of Ecclesiastical History and Law in the university of Munich, a chair which he held,

with the exception of a short interval (1847-49), down to 1871, when he was elected rector of his university. He also represented the same university in the Bavarian chamber from 1845 to 1847, and onwards from 1849, and was elected by a Bavarian constituency to the Frankfort parliament of 1848-49. His life and labours may be conveniently divided into three periods. During the first of these, which extended from 1826 to 1857, he was one of the most energetic defenders of Ultramontanism in Germany, the champion of the independence of the church from the state, and an enemy of Protestantism, formidable not only on account of his energy and indefatigable zeal, but also on account of his learning, his eloquence, and his skill as a writer. The views which he held at this period of his life find expression in his public acts, especially as leader of the Ultramontane party at Frankfort, and in two works, *Die Reformation, ihre innere Entwicklung und ihre Wirkungen* (Ratisbon, 3 vols. 1846-48); and *Luther, eine Skizze* (1851). In 1857 Dollinger visited Rome, and what he saw there, together with the outbreak of the Italian war of 1859, produced a change in his opinions, which he first announced publicly in two addresses delivered at Munich in 1861, in which he propounded his belief that the temporal sovereignty of the pope was not essential to the continuance and progress of the Roman Catholic Church. The enunciation of this view brought down upon his head several fierce attacks from the writers of the Ultramontane party, to which he replied in *Kirche und Kirchen, Papsttum und Kirchenstaat* (1861); and this was followed, two years afterwards, by *Vergangenheit und Gegenwart der katholischen Theologie* (addressed to a conference of Roman Catholic divines at Munich), and by *Die Papstfabeln des Mittelalters*. Whilst the Vatican Council was being summoned to deliberate on the dogma of papal infallibility, Dollinger, along with his colleagues, Professors Friedrich and Huber, assailed the new doctrine in the anonymous *Janus* (1869; 2d ed. as *Das Papstthum*, 1891). In July 1870 the council proceeded to promulgate the decree of papal infallibility; and in the following March Dollinger published a letter, withholding his submission, alike as 'a Christian, a theologian, an historical student, and a citizen.' Excommunicated three weeks afterwards, he took a leading part in the summoning of the congress which met at Munich in September, and out of which arose the Old Catholics (q.v.). The year 1872 marks the beginning of the third period in the learned theologian's career. The position he now took up was indicative of a desire to bring about the union of the various Christian churches, a cause which he advocated, not only in a series of lectures (1872), but also by the active part he took in the Old Catholic conference at Bonn (1874-76). He never officiated as a priest of the new communion, though he defended its position. With Reusch he edited Cardinal Bellarmine's autobiography (1887), and a work on moral controversies in the Catholic Church since the 16th century (1888). In 1888 he published academic lectures (Eng. trans. of first series, *Studies in European History*, 1890), and in 1889 materials for a history of sects. Besides works already named, Dollinger wrote *Hippolytus und Kallistus* (1853), *Heidentum und Judentum* (1857), a treatise on Christianity and the Church in the earliest period (1860), and a collection of documents illustrating the history of the Council of Trent. In 1873 he was made president of the Munich Academy. In 1889 his ninetieth birthday was celebrated by the university with great éclat; and he died at Munich, 10th January 1890.

Dollond, JOHN, a distinguished optician, inventor of the achromatic telescope, was descended

from a French refugee family of Dutch extraction, and was born in London, June 10, 1706. Brought up to his father's occupation of silk-weaving, and engaged at the loom all day, he devoted great part of the night to his favourite studies of mathematics, optics, and astronomy; and even made himself acquainted with anatomy, theology, Greek, Latin, French, German, and Italian. In 1752 he joined his eldest son, Peter (1730-1820), who had started as an optician, and devoted himself to the improvement of the dioptric telescope, in which he was encouraged by the most distinguished scientific men of the time. After a series of well-contrived experiments and researches, carried on for several years, he succeeded in constructing lenses that produced images without any coloured fringe (see **ACHROMATISM**). This was undoubtedly the greatest improvement that the telescope had received since its first invention, though it came out in action for infringement of patent, that in 1733 it had been anticipated by Chester More Hall, who had not, however, made his invention public. The Memoir (published in the *Philosophical Transactions* for 1758) in which he gave an account of his investigations was rewarded by the council of the Royal Society with the Copley Medal. In 1761 Dollond was elected an F.R.S.; he died 30th November of the same year. His two sons continued to carry on the business with great reputation and success. See Kelly's privately printed Life, reproduced in the *Philosophical Magazine* (1804).

Dolmen (from the Celtic words *dauil*, 'a table,' and *maen*, 'a stone') is a modern term applied in archaeology to the megalithic framework of the chambers of chambered cairns, which often survive the removal of the covering mounds of stones and earth for agricultural or other utilitarian purposes, or which may never have been completely enveloped in such a covering. In England, such constructions, consisting of three or more stone props supporting a massive roof stone, were formerly styled *Cromlechs* (q.v.), but this use of the term is now obsolete. The best-known English dolmen is that known as *Kits Coty House* (q.v.), near Aylesford, in Kent. The term dolmen is almost universally employed on the Continent to designate not only the denuded megaliths of a sepulchral chamber, but the whole construction, inclusive of the covering mound or cairn. It is thus synonymous with the descriptive appellation of chambered Cairn (q.v.), and may be taken as a generic name for such sepulchral constructions of the stone age. In France there are thousands of more or less complete dolmens in the wider sense of the term, many of these in Brittany.

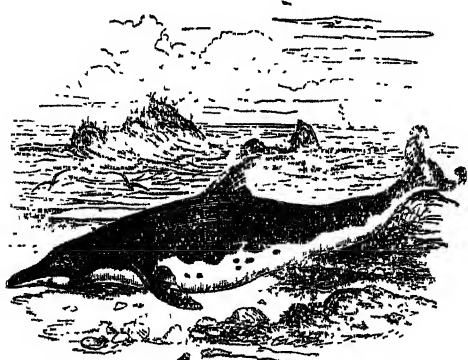

Dolomite, or BITTER SPAR, a mineral consisting of double calcium and magnesium carbonate. The proportions of the two carbonates are very variable, and occasionally the mineral contains a considerable percentage of ferrous carbonate. It crystallises in rhombohedral forms, the faces of the crystals being often curved; its lustre is somewhat pearly or vitreous, and its colour usually white, but variously coloured kinds are not uncommon, such as reddish, brown, green, gray, and black. It effervesces feebly with cold acid. The pure crystallised varieties are known as Pearl Spar. Those which contain a notable proportion of ferrous carbonate are called Brown Spar or Ankerite. Besides these, columnar fibrous and granular or saccharoid varieties are known. Magnesian limestone—a rock occurring abundantly in the Permian System (q.v.)—is composed essentially of bitter spar, and hence is often called dolomite. It is usually white, gray, or yellow in colour, and finely crystalline. In some varieties cellular spaces occur which are often lined with crystals of dolomite.

Other varieties are composed of botryoidal or irregularly-shaped concretionary masses. Most limestones contain some magnesium carbonate, but it is only when the percentage of this salt is considerable that they are called magnesium limestones or dolomites. Magnesian limestone is often used as a building-stone; and it is also burned and made into mortar, but the lime obtained from it remains much longer caustic than lime from common limestone, and is considered of less value for agricultural purposes. In some districts, however, this lime is preferred to purer limes for application to hill-pastures.—Dolomite is named after the geologist Déodat Guy de Dolomieu (1750-1801), who was born at Dolomieu in Dauphiné.

Dolomite Mountains. The distinctive peculiarities of dolomite mountain-scenery, with its jagged outlines and isolated peaks, may be seen on the grandest scale in the south-east of Tyrol and in the Carinthian Alp masses. When the Dolomites *par excellence* are spoken of, it is the Dolomite Mountains of this region that are meant. See books by Gilbert (1862), Miss Tuckett (1870), Amelia B. Edwards (1870), Sinigaglia (1896), and S. H. Hamer (1910), and monograph by Mrs Ogilvie-Gordon (Edinburgh Geol. Soc. 1910).

Dolphin, a name applied to various members of the Cetacean family Delphinidae, but especially to the species of the genus *Delphinus*. This genus is large and heterogeneous, and is split up by some naturalists. The snout is more or less elongated and pointed; the teeth are very numerous, uniform, close-set, and sharp; the fore-limbs are narrow and pointed; there is usually a conspicuous dorsal fin. Like other toothed Cetaceans, the dolphins have a somewhat unsymmetrical skull with many peculiarities, and a single crescentic blow-hole (nostril) on the top of the head. They occur in all seas, and sometimes in rivers, such as the Amazon. None exceed 10 feet in length. They feed principally on fish, but some do not disdain lower animals, such as molluscs, crustaceans, medusæ. In habit they are active, and usually occur in gregarious 'schools.'

The Common Dolphin (*Delphinus delphis*) occurs in the Mediterranean and North Atlantic, and is probably identical with forms from the North Pacific and Australia distinguished as separate

Common Dolphin (*Delphinus delphis*).

species. It is usually not more than 6 to 8 feet in length, of a gray or greenish-black colour above, and white below. The moderately long snout is separated by a transverse pad from the slightly arched forehead. The jaws bear on each side twenty-five to fifty small, conical, sharp teeth, curved slightly backwards. The crescent-shaped tail is keeled above and below. The dolphin feeds chiefly on fishes, which it pursues with graceful gambolings. One young one is born at a time, and tended

with much affection. The animals have a peculiar lowing cry. Their agile evolutions are much observed and admired by voyagers. The flesh is sometimes eaten by sailors. Like other dolphins, it is often called a 'porpoise,' and the French give it the names of *Bec d'Oie* (goose-beak) or *Oie de Mer* (goose of the sea). In ancient times the dolphins were sacred to Apollo, and invested with numerous kindly and marvellous attributes. They drew the car of Amphitrite, and carried Arion upon their willing backs. Its image has been often used as a symbol, from the 'shield of Ulysses' to that of the heir-apparent or Dauphin (q.v.) of France. The anchor and dolphin, the printer's device of Aldo Manuzio, with the motto, '*Festina lente*,' was adopted by him, at Erasmus' suggestion, from a silver coin of Vespasian I. The flesh of the dolphin was formerly esteemed for food. The name has been curiously transferred to the little Coryphenes (q.v.); and it is these scomberoids that are meant when reference is made to the 'dying dolphin's changing hues.'

A rarer species off British coasts is the much larger and heavier Tursio (*D. tursio*), the nesarnak of the Greenlanders. In the North Atlantic, *D. albirostris* and *D. leucopleurus* also occur. There is a pure white dolphin (*D. sinensis*) in the Chinese seas, and a South Sea form (*D. peronii*) without the usual dorsal fin.

In the same family as the dolphin are many well-known forms: the Narwhal (*Monoceros*), the Beluga (*Delphinapterus*), the Porpoise (*Phocæna*), the Grampus (*Orca*, &c.), the Caating Whale (*Globicephalus*), &c. See these articles.

Dolphin, BLACK (*Aphis fabæ*). See APHIDES and BEAN.

Dombœc (book of dooms or sentences), the code of laws attributed to King Alfred, contains few if any original laws, but restores, renovates, and improves those already in existence. A peculiarly Christian character is strongly impressed on the code, which begins with extracts from the Bible, 'The Lord spake all these words, saying, I am the Lord thy God.' Then follow the ten commandments, the part of the Mosaic law relating to criminal offences, and passages from the New Testament. It was ratified by the Witan. Thorpe gives it in his *Diplomatarium Anglicanum ævi Saxonici* (1865).

Dombrowski, JOHN HENRY (1755-1818), a distinguished Polish general, was born near Cracow, and, after serving under the Elector of Saxony, returned to take part in the Polish campaigns against Russia and Prussia in 1792-94. Next entering the French service, he organised a Polish Legion at Milan, and in the campaigns which followed played a distinguished part. After the fall of Napoleon he returned to Poland, and was appointed a general of cavalry and Polish senator.

Domdaniel, a magicians' meeting-place in a cave under the sea, adopted by Southey (*Thalaba*) from the French continuation of the *Arabian Nights*, and often alluded to by Carlyle.

Dome (Ital. *duomo*). Since the time of the Renaissance this term is commonly applied to the external part of the spherical or polygonal roof, of which the cupola (*cupo*, or cup) is the internal part. In Italian usage, however, it has a wider signification than even the first, being used to denote the cathedral or chief church of a town, the house (*domus*) *par excellence*, or house of God; and in Germany, *dom* or *domkirche* is a cathedral. In tracing the historical origin of the dome, we are usually in the habit of regarding it as originating with the architecture of the Eastern empire, because it was at Constantinople and in the Byzantine provinces that its use in ecclesiastical

structures was principally adopted. But it was the Romans who developed the dome, as well as all the other applications of the semicircular arch. Of their success in applying it to large buildings, we have abundant proof in the ancient domes still to be seen in Rome and its neighbourhood. The dome of the Pantheon is still probably the most magnificent dome in existence, and others of smaller size are to be seen in the temples of Bacchus, Vesta, Romulus, Hercules, &c. From Rome it went to Constantinople, and from the same source, also, according to Fergusson, came the few insignificant attempts at domes in the Western empire. The external form of the dome of the church of St Sophia at Constantinople, which became the typical Christian structure of the kind, will be seen in the illustration appended to BYZANTINE ARCHITECTURE (see also ARABIAN ARCHITECTURE, and the illustration of the Taj Mahal at AGRA). The dome of San Vitale, at Ravenna (q.v.), is said to be still more ancient than that of St Sophia, and is a very remarkable structure of the same class. On the church of St Mark, at Venice, there are no less than five domes, the centre one, as is usual in Eastern structures, being much larger than the others. The interior of these domes is covered with Mosaic (q.v.). So far from being peculiar to the few churches we have mentioned, domes occur in those of almost every town along the western shore of the Adriatic, and form, in fact, the chief architectural feature of that side of Italy. From St Mark's the dome was introduced in the 11th century into Périgueux in the south of France, and thus influenced the architecture of a considerable part of that country. The construction of domes in modern times was revived in Rome, by the building of that of Our Lady of Loretto in 1507. But the three most celebrated modern domes are those of St Peter's (q.v.) at Rome, of St Paul's in London, and of the Pantheon in Paris. The following are the dimensions of some of the most important existing domes:

	Feet diam.	Feet high.
Pantheon at Rome	142	143
Baths of Caracalla, Rome	112	116
St Sophia, Constantinople	115	201
St Maria delle Fiore, Florence	139	310
St Peter's, Rome	139	435
St Paul's, London	112	404
St Geneviève, Paris	67	190

In modern times, domes have been constructed with iron of still larger dimensions. Thus that of the Great Exhibition in Vienna was 360 feet in width, and that of the Albert Memorial Hall in London, which is oval, measures 219 by 185 feet in diameter. For a class of ancient dome-roofed structures, see BEEHIVE HOUSES.

Domenichi'no, or DOMENICO ZAMPIERI, a celebrated painter of the Bolognese school, was born at Bologna in 1581. He began his studies under Denis Calvaert, and completed them under the Caracci. During the whole of his career, Domenichino had much to suffer from the jealousy of rivals, who are not free from the suspicion of having caused his death by poison (1641). Though his artistic fame has greatly diminished during recent years, it must be admitted that his works are distinguished by correctness of design, that the heads of his figures in particular are expressive and forcible, and that his draperies are rich and varied in arrangement. The masterpiece of Domenichino, the 'Communion of St Jerome,' 1614 (an easel-picture in the Vatican), though suggested by Agostino Caracci's rendering of the subject, is an accomplished and powerful production. His 'Diana and her Nymphs,' 'Guardian Angel,' 'St John,' and 'St Sebastian,'

also rank among his finer productions, and the 'Cure of the Demoniac Boy,' at Giotta Ferrata, is one of the most admired of his frescoes. Out of Italy, the museum of the Louvre possesses the largest number of Domenichino's works.

Domesday Book, or DOOMSDAY BOOK, one of the oldest and most valuable records of England, contains the results of a statistical survey of that country made by William the Conqueror in 1085-86. The Old English name, *Domes Dag*, 'day of judgment,' has obvious reference to the supreme authority of the book in doom or judgment on the matters contained in it. It was also anciently known as the *Liber de Wintonia*, or Book of Winchester; the *Rotulus Wintonie*, or Roll of Winchester; the *Liber Regis*, or King's Book; the *Scriptura Thesauri Regis*, or Record of the King's Treasury (where it was long kept, together with the king's seal, under three locks and keys); also the *Liber Censualis Anglie*, or Rate-book of England; and the *Liber Judicarius*, or Book of Judgment.

The way in which the survey was made will be best described in the words of the contemporary writer in the Anglo-Saxon Chronicle. At mid-winter in 1085, when the king was at Gloucester, 'he had a great consultation, and spoke very deeply with his witan [i.e. great council or parliament] concerning the land, how it was held, and what were its tenantry. He then sent his men all over England, into every shire, and caused them to ascertain how many hundred hides of land it contained, and what lands the king had in it, what cattle there were in the several counties, and how much revenue he ought to get yearly from each. He also caused them write down how much land belonged to his archbishops, bishops, abbots, and earls, what property every inhabitant of all England possessed in land or in cattle, and how much money this was worth. So strictly did he cause the survey to be made, that there was not a single hide, nor a yardland of ground, nor—it is shameful to say what he thought no shame to do—was there an ox, or a cow, or a pig passed by, that was not set down in the accounts; all these writings were brought to him.'

The survey was made by commissioners called the king's justiciaries, who had the help of the chief men of every shire. By a sworn assize or jury of the sheriffs, lords of manors, presbyters of churches, reeves (i.e. grievers or overseers) of hundreds, bailiffs, and six villeins (i.e. servile tenants) of every village, they made inquest as to the name of the place; who held it in the time of King Edward (1041-66); who was its present possessor; how many hides there were in the manor; how many ploughgates in demesne (i.e. reserved in the lord's own hand); how many homagers or vassals; how many villeins; how many cottars; how many serfs; what freemen; how many tenants in socage (i.e. tenants who rendered services of husbandry); how much wood; how much meadow and pasture; what mills and fish-ponds; how much had been added or taken away; what was the gross value in Edward's time; what the present value; and how much each freeman or socman has or had. They were also to state the value of the land (1) as held in Edward's days; (2) as it had been given by William; (3) as it stood at the time of this survey; and (4) if its value could now be raised.

The returns thus gathered in the several shires, and their hundreds and other subdivisions, were arranged and digested in the record which is now called the Great or Exchequer Domesday. The enumeration of the cattle and swine, which so moved the indignation of the Anglo-Saxon chronicler, though regularly made, was in some cases omitted from the record, because of its ever-fluctua-

ating quantity. By this valuable census there was provided not only exact information of the land and its inhabitants, but also a trustworthy register of appeal for litigious proprietors, a reliable guide for military service, and a practical basis for regulating taxation. The taxes were levied according to the divisions of the country given in the Domesday Book, until 1522, when a new survey, popularly called the *New Domesday Book*, was made.

This great English record was published at the national cost in 1783, in two folio volumes, printed with types cast for the purpose, so as to represent the contractions of the original manuscript; it was ten years in passing through the press. In 1811-16 two supplementary volumes were published, one containing an excellent general introduction, by Sir Henry Ellis of the British Museum, with indices to the places and persons mentioned in the work; the other containing four other records of the same nature: (1) The Exon or Exeter Domesday, being a transcript of the Exchequer Domesday for the counties of Wilts, Dorset, Somerset, Devon, and Cornwall; (2) the Inquisitio Eliensis, a transcript of the survey of the lands of the monastery of Ely, in the counties of Cambridge, Hertford, Essex, Norfolk, Suffolk, and Huntingdon; (3) the Winton Domesday, containing two surveys of the city of Winchester, one made between 1107 and 1128, the other in 1148; and (4) the Boldon Book, a survey of the possessions of the see of Durham, made in 1183. This fourth record is especially valuable, as partially supplying a deficiency in the Domesday survey, which did not extend to the counties of Durham, Northumberland, Westmorland, and Cumberland, either, it would seem, because they had been lately laid waste by the Conqueror, or because his dominion was not fully established in them. A new and better edition of the Boldon Book was issued in

Domesday Book in translation, county by county, with introductions and maps. In 1872 government ordered a general return of owners of lands, to be prepared by the Local Government Board. This modern 'Domesday Book' was published in 1874-76.

Of books on Domesday there are not a few—amongst them Matland's *Domesday and Beyond* (1897); Birch's *Domesday Book* (1887), a succinct and popular account, with a copious bibliography; Léchaudé d'Anisy, *Recherches sur le Domesday* (1842); *Domesday Studies* (1888-91); the Rev. W. R. Byton's notes on several sections (Dorset, Somerset, Stafford, 4 vols. 1877-81, &c.); Freeman's *Norman Conquest of England* (vol. v. 1876); Round's *Feudal England* (1895); Ballard's *Domesday Boroughs* (1904), and *Domesday Inquest* (1906).

Domestic Architecture. The variety of requirements to be fulfilled by the architecture of the house, whether as regards the climate, habits, or employments of different countries, is very great, and the designs and arrangements must therefore throughout the world's history have been infinitely varied. But the construction is generally much less substantial than that of temples and public buildings, and the remains of ancient houses are in consequence comparatively scarce. There are considerable remains, however, of Egyptian and Cretan dwellings (see CRETE), and some idea of those of the Etruscans may be obtained from the arrangement of their tombs. Greek and Roman houses were generally only one story in height, and contained an open atrium with small chambers around it. Beyond this was the peristyle or private department, surrounded with a colonnade, and opening on a garden. In connection with the peristyle were dining-rooms and family apartments. The preservation of the houses of Herculaneum and Pompeii brings before us with great vividness all the domestic arrangements of the classic period.

The Roman dispositions were followed during a great part of the middle ages, but became modified about the 11th century. Thus the peristyle was imitated in the cloister of the medieval monastery, and the Roman 'villa' or country-house became the model of the early castles of southern Gaul. In the villa the large outer courtyard was called the *villa rustica*, containing the granaries, stables, &c., while an inner court formed the *villa urbana*, or residence of the proprietor. The castles were on the same plan, the courts being surrounded with a ditch and palisaded mound, and the owner's house being a wooden redoubt on the top of an artificial mound in the inner inclosure.

During the middle ages and up to the 17th century, the greater part of the houses of the people, including those in the towns, were constructed with wood, the corbelled-out and overhanging upper floors of which are amongst the most picturesque features of medieval architecture both in England and on the Continent. The Normans were the first to introduce stone and mortar construction into castle-building in the 11th century. The well-known Norman keeps were the residences of the nobility in Normandy and England till the 13th century. There are still, however, remains of smaller manors in England dating from that period. These consisted of a two-story plain block, the ground-floor being vaulted, and the upper floor,

Rex tenet in dominio Stocche. De firma regis Edwardi fuit. Tunc se defendebat pro xvij hidis. Nichil geldaverunt. Terra est xvj carucatas. In domo sunt ij carucate & xxiv villani & x bordarij cum xx carucatis. Ibi ecclesia quam Willelmus tenet de rege cum dimidia hida in elemosina. Vicecomes habet xxv solid.

1852 by the Surtees Society, which, in 1857, printed *Bishop Hatfield's Survey*, another record of the possessions of the see of Durham, compiled between 1345 and 1381. A new and enlarged edition of Sir Henry Ellis's *General Introduction to Domesday Book* was published in 1833, in two vols. 8vo. See also Stubbs's *Select Charters*, and Freeman's *Norman Conquest* (vol. v. 1876). In 1861-63 a fac-simile copy was published by the Ordnance Survey, by photozincography; and the *Victoria History of the Counties of England* has gone on publishing the

which contained the living-rooms, entering by a separate outside stair. In the following centuries additions were made to the accommodation to suit the enlarged requirements of the times, until the buildings came finally to surround a courtyard and form a quadrangle. Most of the great castles and mansions of the 15th and 16th centuries were erected on this plan, and those built in the time of Queen Elizabeth were often on a great scale, and contained nearly all the accommodation required at the present day. Smaller mansions and houses were on various plans, and in town-houses the interior court, surrounded with projecting balconies or galleries, was common.

Under the Renaissance, town-houses in streets lost their distinctive qualities, being all designed so as to form as it were one flank of an extensive palace or single edifice. This monotonous arrangement is now being gradually departed from, and each house is beginning to be designed, as it should be, independently.

The domestic architecture of modern times has this peculiarity, that it extends its influence so as to include all classes of dwellings, even the humblest; and the houses of farm-servants and town artisans now receive as much care in their design, in order to render them comfortable and sanitary abodes, as the palaces and mansions of the wealthier classes.

Hudson Turner, *Domestic Architecture of the Middle Ages*; D. MacGibbon and T. Ross, *Castellated and Domestic Architecture of Scotland*.

Domestication, the modification of animals by deliberate human interference with their food and surroundings, with the work or functions they perform, but especially with their breeding. The influence of man on animals extends, however, far beyond those usually regarded as domesticated, and it is not possible to draw a perfectly hard and fast boundary line. Man has exterminated some animals—e.g. birds, and propagated others—e.g. fishes; he has made many become rare, shy, and cunning, while others (e.g. crickets) find shelter in his dwellings; he has kept some captive, like the fish in the pond; tamed others individually for his service, like falcons and cheetahs; he has preserved some artificially from their enemies, because of their rarity, and others because of their utility, but without in any of these cases much modifying them. None of these are in the strict sense domesticated. It is only when a distinct breed has been produced by human interference, in most cases deliberately by artificial selection, that we are justified in calling the result domestication. Strictly 'domesticated animals' correspond to strictly 'cultivated plants'; in both cases the organisms have been modified, more or less fixedly, from their natural or wild state, by changes in food and environment, function and breeding.

Domestication began long before the dawn of history (see AGRICULTURE, ANTHROPOLOGY, DOG, STONE AGE). The domestic animals are discussed under separate articles; but a list of representative forms may be given here. Among lower animals, Silk-moths (see SILK) and hive Bees (q.v.) have been for long controlled, and to a limited extent modified. Among fishes, Goldfish (q.v.) may certainly be regarded as domesticated for decorative purposes. Birds include many illustrations of domestication—pigeons, fowls, ducks, geese, peacocks, turkeys, guinea-fowls, canary-birds, &c. Among mammals, dogs and cats, horses and asses,

cattle, sheep and goats, camels, llamas, reindeer, pigs and rabbits, &c., have been domesticated, and have given rise to many different breeds. The complete list is not a long one, though it will probably be increased. To admit of domestication, animals must generally be social and docile in their habits, and must be capable of retaining fertility under changed conditions.

The process of domestication, as far as deliberate control is concerned, is for the most part equivalent to selective breeding. Forms with useful varieties are isolated from the mass, and allowed to breed together, the most desirable results are again selected for breeding, and so on, till a domesticated breed of the same animal is established (see BREED). Different breeds differ from natural species in being usually mutually fertile. In other words, while two domestic races may be externally more different than are two nearly related species in nature, the reproductive elements in the first case cannot differ as they must do in the second. Thus crossing is usually successful between domestic breeds, only rarely between adjacent natural species. When we pass beyond selective breeding to inquire into the conditions of variation, a much more difficult problem is raised. We cannot do more than refer to the probably inherent variability of the germ-cells, to the oscillations in their nutrition which probably provoke changes, to deeply saturating environmental and functional influences which may serve as variational stimuli to the germ-plasm, and to the opportunities for new permutations and combinations that are afforded by the intricate changes that go on in connection with maturation and fertilisation. Modern work has made it clear that in many cases man simply assists in the 'unpacking' of the extremely complex inheritance of the wild type. What look like very novel products are sometimes the result of the dropping out of certain factors in the old or the result of rearrangement. What is called reversion of domesticated breeds is often at least a process of 'repacking' when factors that have been analysed apart come together again.

The results of domestication are very varied. Sometimes the changes induced and cultivated have been comparatively slight, in other cases they have amounted to the evolution of new species. Superficial alterations of colour and skin, hair, and feathers; deeper changes in the less plastic skeletal, muscular, alimentary, and other systems; increased fertility on the one hand, sterility on the other; alteration in mental and emotional characters; the perfecting of a racial characteristic in one case, its loss in another; general progress in some forms, utilitarian degeneration or extraordinary abnormality in others, are abundantly illustrated in Darwin's classic work on variation under domestication. The constant tendency to Atavism (q.v.) or reversion; the danger of carrying selection of a given character too far (see BREED); and the relations to Heredity (q.v.) and Evolution (q.v.) are discussed elsewhere.

See ACCLIMATISATION, CULTIVATED PLANTS, VARIATION; Darwin, *Animals and Plants under Domestication* (1868); Victor Hehn, *Kulturpflanzen und Haustiere* (new ed. 1902); N. S. Shaler, *Domesticated Animals* (1896); Keller, *Naturgeschichte der Haustiere* (1905).

Domestic Economy is a tautological but convenient expression. *Oikonomia*, the Greek word from which *economy* is directly derived, means simply household management. But the reference to the household having gradually been lost, the art of managing domestic affairs in the best and thriftiest manner was, as *Domestic Economy*, distinguished from *Political Economy*. As a subject of education in schools, the term is made to cover many matters treated separately in this work—

food, the value of the various kinds, the functions of food, and its preparation; clothing, its various kinds, the making and repairing of it; washing; domestic utensils; the lighting, warming, ventilation, and sanitation of houses; hygiene, the laws of health, sickness, and nursing; as well as thrift, the more especial subject of domestic economy. Information on most of these subjects will be found in very many articles throughout the work: see amongst others those on FOOD, DIET, GERM THEORY, DIGESTION, COOKERY, BREAD, HYGIENE; INDIGESTION, CONSTIPATION, CATARRH, and the other articles on ailments; NURSING, BUILDING, SEWAGE, VENTILATION, WARMING.

Domett, ALFRED (1811-87), poet and premier of New Zealand, where he lived from 1842 to 1871. He was born at Camberwell, like his lifelong friend Browning, who refers to him as 'Waing'. He studied at St John's College, Cambridge, and was called to the bar in 1841.

Domfront, an old town of the French department of Orne, on a rock overlooking the Varenne, 43 miles WNW. of Alençon, has an old church and ruins of a castle; pop. 4000.

Domicile, a man's legal place of abode, or the place which the law will hold to be his residence. In determining questions of domicile, the law endeavours to follow the facts of each case, and, consequently, the legal as well as the natural view of the matter is expressed in that definition of a domicile in the *Corpus Juris*, which says 'Every man has his domicile where he has placed his hearth, and centred his fortunes and affairs; whence he goes not forth without an occasion; from which, when he is absent, he is said to be abroad; and to which, when he returns, he is said to cease to be abroad.'—Cod. 10, tit. 39, s. 7. Even in Rome, questions of domicile were not without importance, for the empire was divided for purposes of domestic government, and the inhabitant of one province was not subject to the magistrates of another. But it was in modern times, when Europe was divided into many independent kingdoms, and America was formed out of states having different local customs and laws, that the law of domicile assumed its full importance. It now constitutes one of the most difficult branches of private International Law (q.v.). The following are its most general rules: (1) The place of birth is the original domicile of every one, provided that, at the time of his birth, it was the domicile of his parents; but if his parents were then on a visit or on a journey, the home of the parents will be the domicile of birth, nativity, or origin (*domicilium originis*). (2) If the child is illegitimate, it follows the domicile of its mother. (3) The domicile originally obtained continues till a new one is acquired. (4) Minors are generally deemed incapable of changing their domicile of their own accord, but it may be changed by a change in the domicile of the parents, which it follows. (5) If the husband and father dies, his last domicile is that of his widow and children. (6) A wife follows the domicile of her husband. (7) No person can have more than one domicile in the proper sense of the term at any given moment. (8) If a person of full age, having a right to change his domicile, takes up his abode in a new place, with the acknowledged intention of remaining permanently fixed there (*animo manendi*), that place immediately becomes, and that which he has quitted ceases to be, his domicile. Questions as to what amounts to intention, or what circumstances constitute sufficient proof of intention of remaining, or quitting a place of residence, are amongst the most difficult in the law of domicile. Most persons who are resident abroad have a sort of floating

intention that, in certain conceivable circumstances, they will return to their native country, and to these vague feelings they give expression in a manner more or less vague.

One of the most important effects of the law of domicile, which formerly gave room for litigation, was as to the validity of the will which a deceased person leaves—the English rule being, that it must be according to the law of the domicile, wherever the will was made, though the law of Scotland allowed a will also to be good if it was executed according to the law of the country where it was made. A statute, however, was passed in 1861, by which the law was made uniform, so that the will of a British subject, as regards personal estate, made out of the United Kingdom, is now deemed valid, wherever his domicile may be, if the will is conformable to the law of the country where made, or to the law of the domicile of origin. And by a later statute passed in 1868, it has been provided that even as regards real or heritable estate, an English will is to have effect given to it as regards property situated in Scotland. In each case the presumed intention of the testator will determine by which law the will is to be construed. It is impossible here to enumerate the various other effects of the law of domicile. Generally, it may be stated that it regulates the succession to property. As regards personal or movable property, this is universally conceded. It is said to follow the person (*mobilia inchoerent ossibus*). Accordingly, such property is everywhere distributed after death according to the law of the country of which the deceased died a domiciled citizen. In the case of heritable or real property, however, the same rule is not universally applied. By the legal systems of the Continent, domicile as a rule governs the succession, but in Great Britain and the United States, real property descends in accordance with the law of the land in which it is situated (*lex rei sitæ*). The transmission of a debtor's estate upon divestiture by bankruptcy stands in a similar position to that of succession by death—British and American laws making the same distinction as regards distribution between movable and heritable estate.

Besides domicile proper, of which we have just been treating, the term is sometimes applied in a special and restricted sense. Thus the expression 'Matrimonial Domicile' was occasionally used to express the character of residence supposed to be sufficient to constitute jurisdiction in questions of marriage and divorce. Although the courts in one or two cases sustained their jurisdiction where the evidence of domicile was slender, it was doubtful how far these cases were authoritative, and the doctrine of 'Matrimonial Domicile' was finally repudiated by the House of Lords in 1895 (see MARRIAGE). Another common expression is 'Domicile of Citation,' which simply signifies residence for forty days within the territory of a particular court. Such residence is sufficient to constitute jurisdiction for citation of a defender in all personal actions. Again, the term domicile is sometimes used quite incorrectly to describe the kind of residence required for the purposes of parish relief in Scotland (see POOR LAWS; SETTLEMENT, LAW OF). But the rules for determining such residence have little bearing upon questions of domicile proper. See DICEY ON DOMICILE; and notes to the French translation of Dicey by M. Stocquart.

Dominant, in Music, the fifth above the tonic: the ruling or governing tone of the key. See HARMONY.

Dominant, in Mendelism. See HEREDITY.

Dominic, St. See DOMINICANS.

Dominica (Fr. *Dominique*), the largest and most southerly British island in the Leeward group of the Lesser Antilles, lies midway between the French islands of Martinique and Guadeloupe, and has an area of 300 sq. m. The population (37,000) is mostly negro. The Caribs (400), who occupy a large reserve on the Windward side of the island, are gradually becoming so intermixed with the negroes that the pure Carib, the 'Franc Carib,' will soon be non-existent. They are very peaceable and retiring, and live on fish, and vegetables and fruits which they cultivate. Dominica is of volcanic origin, with many hot and sulphureous springs. In 1880 there was a great eruption of volcanic ash from the 'Boiling Lake' at the southern extremity of the island. The temperature is cool and even chilly in the mountains, but sultry on the coast, where the yearly mean is 89° F.; rain falls nearly every month, and the annual rainfall is 83 inches. Nearly one-half of the surface consists of wooded mountains and deep ravines, and at one point the surface attains an elevation of 5300 feet. Dominica has one of the best tropical botanic gardens in the world. Attractive as it is to the artist and traveller, the rugged, broken, and precipitous character of Dominica is very disadvantageous to the settler, and long confined agriculture to a narrow strip along the coast, the pathless forests of the interior remaining practically as much a *terra incognita* as when Columbus first sighted the island. Trade is chiefly with the United States, Canada, and Britain. The principal products are fruit, cocoa, essential oils, lime-juice, coffee, sugar, and timber. The fisheries are valuable. About a third of the area is now cultivated. The capital of the island is Roseau, a port on the west coast, with a pop. of 7000. Dominica is a member of the Leeward Islands colony, and sends representatives to the general legislative council; but it has its own administrator and legislature, since 1925 partly elected. The majority of the inhabitants are Roman Catholics; religious equality now prevails, but till recently the clergymen of the Church of England were paid from the public funds. Dominica was discovered by Columbus, on his second voyage, on Sunday (whence its name Dominica—i.e. 'the Lord's Day'), 3d November 1493. It was a source of strife to French and English until 1648, when it was formally declared by the treaty of Aix-la-Chapelle a neutral island; but in 1759 it was captured by England, and in 1763 ceded by France, which, however, held it again in 1778–83, and in 1802–14, when it was finally restored to England. See Froude, *The English in the West Indies* (1888); Grieve, *Notes upon Dominica* (1907).

Dominical Letter, or SUNDAY LETTER, is one of the seven letters, A, B, C, D, E, F, G, used in almanacs, &c., to mark the Sundays throughout the year. The first seven days of the year are marked in their order by the above letters in their order, then the following seven, and all consecutive sets of seven days to the end of the year, are similarly marked; so that the 1st, 8th, 15th, 22d, &c. days of the year are all marked by A; and the 2d, 9th, 16th, 23d, &c., by B; and so on. The days being thus marked, it is evident that on whatever day the first Sunday of the year falls, the letter which marks it will mark all the other Sundays in the year, as the number of the letters and of the days in the week is the same.

As the common year consists of fifty-two weeks and one day over, the dominical letters go backwards one day every common year. If the dominical letter of a common year be G, F will be the dominical letter for the next year. As a leap-year consists of fifty-two weeks and two days, the letters go backwards two days every leap-year. If in the beginning of a leap-year the dominical letter be G,

E will be the dominical letter for the next year. This extraordinary retrocession, however, is made to take place at the intercalary day (the 29th February) by the artifice of marking it by the same letter as the day preceding it, and thus the next Sunday is marked by the letter preceding that which marked the Sundays before the intercalary day. Suppose the 28th February in a leap-year to be a Sunday, and marked by F, it is evident that the dominical letter for the rest of the year will be E. As every fourth year is a leap-year, and the letters are seven in number, it is clear that the same order of letters must return in four times seven, or twenty-eight years, which would, but for the leap-years, recur in seven years, and hence the Solar Cycle (see PERIOD). The dominical letters were first introduced into the calendar by the early Christians, to displace the nundinal letters in the Roman calendar. They are of use as a means of discovering on what day of the week any day of the month falls in a given year (see EASTER). Rules and tables for finding them are given in prayer-books, breviaries, &c., as well as in works on dates. See CALENDAR, CHRONOLOGY.

Dominican Republic, or SANTO (commonly SAN) DOMINGO, a state formed of the eastern portion of Hayti (q.v.), and embracing about 19,000 sq. m., or over two-thirds of the whole island. The pop. at the census of 1921 was 897,403; most of these are negroes or mulattoes, but the whites are comparatively more numerous and influential than in the Haitian Republic. The state religion is Roman Catholic, others being tolerated; the prevailing dialect is Spanish. Civilisation has not reached a high level; primary instruction, however, is now gratuitous and obligatory, and of late years the country has made considerable progress under the impulse of American enterprise and guidance. Except on the coasts, not much timber has been cut. The forests furnish mahogany, satin-wood, dye-woods, cedar, and pine. Large sugar plantations and factories have been developed in the south and west; tobacco, coffee, bananas, and cocoa are grown. Maize and tropical cereals are successfully cultivated. Cattle are raised, and beeswax produced. Copper is worked. Gold, silver, quicksilver, nickel, iron, petroleum, salt, and coal are found; and there are 150 miles of railway. Commerce is mainly with the United States, England, France, and Germany. The executive of the republic is vested in a cabinet consisting of the president and seven ministers, and the legislative power in a congress of twenty-four deputies and twelve senators. The capital is San Domingo (q.v.).—The early history of this portion of the island, which remained Spanish when the western part was ceded to France in 1697, and which was united with the neighbouring state in 1795–1808 and 1822–43, properly belongs to that of Hayti. In 1843 it assumed a separate standing as the Dominican Republic, the anarchy and misrule of which it exchanged in 1861 for the despotism of its former masters. But the harsh Spanish rule brought on a revolt in 1863, and the republic, reconstituted in 1865, has since maintained a troubled existence. Owing to the heavy foreign debt, the customs were submitted to the United States in 1907. The prosperity that followed was broken by a series of revolutions. The United States sent commissioners to advise, and in 1916 placed the administration in the hands of American naval officers. American control, except in the matter of customs, was withdrawn in 1925.

See Keim, *San Domingo* (1870); Hazard, *Santo Domingo* (1873); Hesketh Prichard, *Where Black Rules White* (1900); Schönrich, *Santo Domingo* (1918); the Military Governor's Report (U.S. Navy Dep., 1920).

Dominicans, an order of preaching friars founded at Toulouse in 1215-16 by Dominic de Guzman. Dominic was born in 1170 at Calaruega in Old Castile, and studied at Palencia. Here he acquired a great name for piety and learning; so much so that in his twenty-fourth year his diocesan, the Bishop of Osma, made him a canon of his cathedral, and relied mainly on Dominic's aid in his design of reforming the whole chapter according to the rule of St Augustine. The young man led a life of rigorous asceticism, and devoted himself at the same time to missionary labours among Mohammedans and 'heretics.' In 1204 he accompanied his bishop on a political mission, and had to pass three times through the south of France. That part of the country was almost entirely peopled by Albigenses (q.v.), and the labours of papal legates and Cistercian abbots for their conversion had been all in vain. The turning-point of Dominic's life had come. He undertook the care of the work; he substituted poverty for the prelatic pomp, love for force. He travelled from place to place on foot, bearing St Paul's epistles in his hands and preaching everywhere. He continued his labours for ten years, gathered like-minded companions round him, whom he trained after his own heart, and for whom he afterwards (1215) founded the first house of his followers at Toulouse. He also set up at Prouille an asylum for women who had been heretics or were in danger from heretical influence, and this institution developed into an order of nuns. Unhappily, events occurred which have had an evil influence on the history of his order. Innocent III., incensed by the murder of his legate, Peter of Castelnau, called the barons of northern France, led by Simon of Montfort, to a crusade against the 'heretics.' Dominic participated in many of the doings of the crusaders, though it is maintained that his influence was directed towards mercy, and that his own character was peculiarly gentle and kindly. In 1215 Dominic, now in high favour with ecclesiastical authority, went with Fulbo, Bishop of Toulouse, to the fourth Lateran Council. The council was averse to the foundation of new orders. Still Innocent III. promised approval, on condition that the new order adopted an old rule. Dominic chose the rule of St Augustine, borrowing some additional statutes from the Premonstratensians, and authorisation was given in the following year by Honorius III. A little later he became 'Master of the Sacred Palace,' an office which has continued in the order. In 1220 the Dominicans, in imitation of their Franciscan brethren, adopted a poverty so rigid that not even the order as a corporation could hold houses or lands, and thus they forced themselves to become mendicants or beggars. Next year Dominic died. He had lived to see his order occupying sixty houses and divided into eight provinces. It had spread to England, where the first foundation was at Oxford, and where from their dress they were called Black Friars; to northern France, where their house of St James earned for them the name of Jacobins; to Italy, to Spain, to Austria. He was canonised in 1233 by his friend Gregory IX.; his festival falls on 4th August.

We have identified the Dominicans in general with the friars, and this is justified by ordinary language, but strictly speaking the friars are only the first order of St Dominic. They are bound by the usual solemn vows of poverty, chastity, and obedience; they are forbidden ever to eat flesh-meat; they rise in the middle of the night for prayer. They are subject to a general, elected, according to a recent enactment, for twelve years. Under him are the provincials, each of whom rules in a province; lastly, there are the priors of the

individual houses. All these officers are elected by popular vote and for a limited term. Their constitutions were put into shape by Raymond of Pennafort, third general; but even since then great changes have been made, among which the permission to hold immovable property, initiated by Martin V., and extended by Sixtus IV. to the whole order in 1477, is especially noteworthy. The function of the order is indicated by their name, 'the order of preachers.' They are therefore missionaries in foreign lands and missionaries at home, and everywhere they have made the rosary popular in the Catholic world. They are the order which has concerned itself specially with the guardianship of the faith. The scholastic theology is almost the creation of great Dominicans, such as Albertus Magnus and Aquinas, and among their illustrious preachers was the martyr Savonarola. They have been the favourite inquisitors, and a Dominican always presided over the Inquisition. But their influence is now a thing of the past, except for the power still exerted by their great writers of the middle ages. The Jesuits have displaced them as teachers and preachers; though the fame of the order was revived for a time by the genius, the eloquence, and noble character of Lacordaire, who restored it to France. At present the order is chiefly engaged in preaching missions and retreats. They have several houses in the United Kingdom—e.g. at London, Newcastle, Woodchester, &c. They wear a dress of white wool, with a black mantle and pointed hood.

The second order consists of nuns, bound by solemn vows, and engaged to strict inclosure, perpetual abstinence from flesh-meat, &c. They were, as we have seen, instituted by St Dominic.

The Tertiaries or third order are said to have arisen from the 'militia of Jesus Christ,' drawn together by St Dominic to assist in resisting and persecuting the Albigenses. In their present form they are an imitation of a similar institution among the Franciscans. They are either people in the world, free to marry, but following certain ascetical rules; or else are women living as nuns in community under simple vows. They are also known as the Brothers and Sisters of Penance.

See Lives by Lacordaire (1841), Alemany, Miss Drane, Herkless, and Guiraud (trans. 1901); and for the order, works by Helyot, D'Anzas (1874-76), Devas (1913), Jarrett (1921).

Dominie. See DOMINUS.

Dominion, a term for the self-governing British colonies, specifically Canada and New Zealand. See Professor A. B. Keith's *Responsible Government in the Dominions* (1912), and his articles in this work, COLONY, FEDERATIONS AND UNIONS.

Dominis, MARCO ANTONIO DE, born in 1566 in the Dalmatian island of Arbe, was carefully educated by the Jesuits. From Bishop of Segni he had become Archbishop of Spalato, when, getting involved in the great quarrel between the papacy and the Republic of Venice, he found it expedient to resign his see. His reasons he gave in his *Consilium Profectionis* (1616). In 1616 he came to England, where he was hospitably received, and in 1618 was by James I. appointed Master of the Savoy, and in 1619 Dean of Windsor. In 1617 he published the first part of his *De Republica Ecclesiastica*, a work in which he endeavoured to show that the pope had no supremacy over other bishops, but was only *primus inter pares*. In 1619 he published without authority Sarpi's famous *History of the Council of Trent*. His enemy Paul V. died in 1620, and was succeeded by Gregory XV., a relative and fellow-countryman of De Dominis, who moreover began to find himself unpopular from his avarice, his pretentiousness, and his corpulence, and from interest, much more than

conscience, began to intrigue with Rome for a return to the bosom of the church. These negotiations had to be carefully kept secret from the king, but at length in the January of 1622 De Dominis wrote to James expressing his intention to leave England. The king was indignant, and when the negotiations of the ecclesiastics whom he sent to reason with him failed, De Dominis was commanded to leave the kingdom within twenty days. While waiting at Brussels for the pope's permission to go to Rome, he published his *Consilium Redatus*, in which he frankly gave the lie to every statement in his former tract, and denounced the Church of England as a wretched schism. His tract was replied to by Crakenthorpe in his *Defensio Ecclesie Anglicanæ*. De Dominis now went on to Rome, but was at once seized by the Inquisition, and flung into prison, where he soon died in 1624. Being subsequently condemned as a heretic, his body was exhumed and burned. While yet a professor of Mathematics at Padua, De Dominis wrote his *De Radis Visus et Lucis in Vitris Perspectivis et Iride* (Venice, 1611). He was the first to point out that in the phenomenon of the rainbow the light undergoes in each rain-drop two refractions and an intermediate reflection.

Dominium, a Roman law term, which has been received into the technical language of most of the legal systems of Europe. It may be described as a full legal right in and to an object—as the right from which alone legal possession could flow, but which actual possession alone could never confer, unless such possession had endured for the period of legal prescription. The right to possess is thus distinguished from the right arising from possession, which is the usufruct. See EMINENT DOMAIN.

Domino, the name formerly given to the hood or cape worn in winter by priests while officiating in cold edifices. It is now used to signify a masquerade costume, consisting of an ample cloak with wide sleeves and a hood. See MASQUERADE.

Dominoes, the name of a game, usually played with 28 oblong, flat pieces of ivory or bone, &c., called *cards*, each of which bears two numbers marked by points from blank to six. The player wins who has first played out his cards, or, if this has been found impossible, who has the fewest points on the tablets still remaining. Regular domino players recognise only the two-handed games—viz. the *draw* game, and its variation the *matador* game, for a description of which a manual of games should be consulted. The game is seemingly of Italian origin, and has spread into all countries of the world; but nowhere is it so popular as in the cafés of France and Belgium.

Dominus, the Latin word which we commonly render by 'lord,' but which more properly signifies the master of a house, and his eldest son, as opposed to slave (*servus*). The term is applied by Christians to God and to Jesus as himself God. The Scottish 'dominie,' in the sense of school-master, is of course taken from it, as is the same term in America, where in some places it is the title of a minister of the Dutch Reformed Church, and in others is applied to Protestant clergymen generally. Don (q.v.) also is a derivative.

Domitianus, T. FLAVIUS, emperor of Rome from 81 to 96 A.D., was the son of Vespasian, and younger brother of Titus, whom he succeeded on the throne. The earlier years of his reign were on the whole advantageously occupied for the public benefit. Many good laws were passed, the provinces carefully governed, and justice rigidly administered. As he grew older, however, his ambition, his jealousy, and his pride, wounded by the failure of his campaigns against the Dacians and the Marcomanni, in 87, began to instigate him to

the most atrocious cruelties. By murder or banishment, he deprived Rome of nearly every citizen conspicuous for talent, learning, or wealth. It was his jealousy that recalled Agricola from his career of conquest in Britain, and most likely caused his death. The horror of the time is reflected in the pages of Tacitus and Juvenal. To win the army, he greatly increased the pay of the soldiers, and secured the favour of the people by prodigal largesses and gladiatorial shows and games, in which he sometimes took part in person. His cruelties became at length so intolerable, that a conspiracy—encouraged, if not organised—by his wife Domitia, whom he had doomed to death, was formed against him, and the tyrant fell under the dagger of the assassin, 18th September 96.

Domo d'Os'sola, a charming little town in the extreme north of Piedmont, at the foot of the Simplon, near the right bank of the Toce. It has a cathedral, and is a starting-point for tourists in the southern Alps. Pop. 6000.

Domremy-la-Pucelle, a village in the French department of Vosges, on the Meuse, 8 miles N. of Neufchâteau, interesting as the birthplace of Joan of Arc (q.v.), of whom there is a statue, and whose house contains relics.

Don, a river of the West Riding of Yorkshire, rising in the Penistone moors on the borders of Derbyshire and Cheshire, and running 70 miles south-eastward and north-eastward past Sheffield, Rotherham, Doncaster, and Thorne, till it falls into the Ouse at Goole. It is navigable below Sheffield by the aid of artificial cuts and canals.

Don, a river of Aberdeenshire, rising close to the Banffshire boundary in a peat-moss 1980 feet above sea-level, and winding 82 miles eastward till it falls into the German Ocean, 1 mile N.E. of Old Aberdeen, and not far below the 'Auld Brig o' Balgownie' (circa 1320), commemorated in Byron's *Don Juan*. Its chief affluent is the Ury. The Don is a capital salmon river.

Don (ancient *Tanais*), a river of Russia, having its source in a small lake in the government of Tula. It flows in a general southerly direction through the governments of Tula, Riazan, Tambov, Voronej, and the country of the Don Cossacks, and enters the Sea of Azov by several mouths, of which the Aksai is the most considerable. The Don has a length of 1125 miles, and drains an area of 165,500 sq. m.; its numerous affluents include the navigable Voronej, Donetz, Khoper, and Medveditza, and the Vasovka, the Sosna, and the Manytch. The course of the main stream is obstructed by frequent sand-banks; and when the ice melts it overflows its banks for miles, so that in many places the village houses are raised on piles. The Don is navigable for large boats below Voronej, and in its upper course is connected by canal and railway with the Volga, by which means the produce and manufactures of the interior are conveyed to the southern provinces of Russia. A great canal from the Don to the Volga, at the point where the lower courses of the two rivers most closely converge, has recently been proposed. The waters of the Don abound in fish; but a monopoly of the fisheries has been enjoyed since 1637 by those dwelling on the river's banks. See COSSACKS.

Don, or DOM (Lat. *dominus*, 'lord') a title originally assumed by the popes, from whom it descended to bishops and other dignitaries, and finally to monks. In France, the title *don* was conferred on the Carolingian kings; in Portugal and Brazil it became the universal title of the higher classes. The Spanish *don* was originally confined to the nobility, but is now bestowed by courtesy as indiscriminately as the English *Mr* or

Esq., or the German *Herr*. The feminine is *doña* (Ital *donna*). The *Dan* in 'Dan Chaucer' is a form of the same word, and we still speak of 'college dons', Roman Catholic dignitaries, especially Benedictines, are called *Dom*.

Donabyú, a small town of Burma, on the right bank of the Irawadi, 35 miles S. of Henzada.

Dona Francisca, a German colony in the Brazilian province of Santa Catharina, lying between the Serra do Mar and the ocean, 14 miles inland from the port of São Francisco. Chief town, Joinville.

Donaghadee, a seaport and bathing-place in the north of County Down, on the Irish Channel, 19 miles ENE. of Belfast, and 21½ miles across from Portpatrick in Scotland, with which it is connected by a submarine telegraph cable. It lies in a crescent round the harbour, and exports cattle and farm-produce. Its fine lighthouse shows a fixed light visible 12 miles; a conical mound near (140 feet high) commands a fine prospect. Pop. 2200

Donaldson, JAMES (1751-1830), an Edinburgh newspaper proprietor and bookseller. His father, Alexander Donaldson, took a leading part in the issuing of cheap editions of works newly out of copyright, which led to a famous litigation, decided in his favour by the House of Lords in 1774. James Donaldson added largely to the wealth acquired by his father, and left about £240,000 to found a hospital or school for 300 poor children, many of whom from the beginning were taken from the class of the deaf and dumb. The hospital was built in 1842-51 from designs by Playfair, at a cost of about £120,000.

Donaldson, JOHN WILLIAM, D.D., philologist, was born in London, 7th June 1811. A merchant's son, of Scottish ancestry, he was articled as a boy to his uncle, a solicitor; but his success in an examination at University College, London (1830), changed his plans, and next year he went up to Trinity College, Cambridge. He graduated in 1834 as second classic and senior optime, and became a fellow and tutor of his college. From 1841 to 1855 he was headmaster of Bury St Edmunds grammar-school (he almost emptied it); thereafter he tutored at Cambridge with great success, till his death, from overwork, in London, 10th February 1861. Donaldson's *New Cratylus*, or *Contributions towards a Knowledge of the Greek Language* (1839), is a work remarkable for research, erudition, and boldness, and as being the first attempt on a large scale to familiarise Englishmen with the principles of comparative philology, established by the great scholars of Germany. In *Varronianus* (1844) he undertook to accomplish for Latin what in the *New Cratylus* he had done for Greek. Unluckily, Professor Key had here in a measure forestalled him. *Jashar*; *Fragmenta Archetypa Carminum Hebraicorum* (Berlin, 1854) sought to distinguish by critical tests the fragments of the lost Book of Jashar or Jasher (q.v.), imbedded in the Hebrew Pentateuch. It is a too clever piece of rash and ingenious speculation, which not only roused much 'odium theologicum,' but was severely handled by Ewald; nor did Donaldson better his position by his *Christian Orthodoxy reconciled with the Conclusion of Modern Biblical Learning* (1857). The *Theatre of the Greeks*, though originally by Buckham, was so recast by Donaldson as to be practically his; to him, too, belongs the completion of K. O. Müller's *History of Greek Literature*; and his Latin and Greek grammars claim mention. Crabb Robinson, in his Diary, gives a vivid conception of Dr Donaldson's kindness, ready wit, and great conversational powers.—His youngest brother was the Australian

statesman, Sir Stuart Alexander Donaldson (1812-87).

Donatello (properly called DONATO DI BETTO BARDI), the greatest of the early Tuscan sculptors, was born at Florence in 1386, the son of a wool-merchant, and was apprenticed to a goldsmith, probably Bartolo, the stepfather of Ghiberti. He became the friend of Brunelleschi, ten years his senior, who directed and influenced his art. At the age of fifteen he visited Rome in his company, and for several years the pair supported themselves as goldsmiths, and so were enabled to study the remains of antiquity in sculpture and architecture. Among the works probably executed before he left Florence are the wooden crucifix in Santa Croce; the wooden statue of the Magdalene, in the Baptistery; and the marble St John at the Bargello; while among the earliest of his productions after his return are the marble figures of the prophets for the cathedral, and an Annunciation in the Cavalcanti Chapel in Santa Croce. A higher level was reached in the marble statues of Saints Peter, Mark, and George, for the exterior of San Michele (1408-16). These were followed by the tombs of Pope John XXIII. in the Baptistery (1426), of Cardinal Brancacci in St Angelo a Nilo in Naples (1427), and of Bartolomeo Aragazzi at Montepulciano (1427-29), works in which he was aided by Michelozzi. The influence of his study of the antique is very visible in his bronze statue of David, now in the Bargello Museum, Florence, where also are his celebrated marble bas-reliefs of singing and dancing children, originally designed as a balustrade for the organ of the cathedral; while the bronze statue of the Condottiere, Erasmo da Nari, called Gattamelata, at Padua, is a noble example of his equestrian portraiture. He died at Florence, 13th March 1466, and was buried in San Lorenzo, where his last works, two bronze pulpits, were completed by his pupil Bertoldo. The life of Donatello marks an epoch of art. He may be regarded as the founder of sculpture in its modern sense, as the first producer, since classic times, of statues, complete and independent in themselves, and not mere adjuncts of their architectural surroundings. He was also a perfect master of work in relief, admirable in the gradation of tone which he attained, and in his beautiful treatment of various planes. The distinction which marks his work was caught from the antique; but all that he did is stamped with his individuality, and vivified by his powerful grasp of character and expression.

See, besides Vasari's *Lives*, the biographies by Müntz (Paris, 1885) and Hemper (Innsbruck, 1887); and in English the short Life by Hope Rea (1900) and the more exhaustive work by Lord Balcarras (1903); also books by Tschudi (Turin, 1887), Schmarzow, Reymond, Bode, A. G. Meyer (1903), and Maud Crutwell (1911).

Donati, GIAMBATTISTA (1826-73), astronomer, born at Pisa, was appointed in 1852 assistant at the observatory in Florence, of which he became director in 1864. Here he discovered, *inter alia*, the brilliant comet of 1858, which is known as Donati's comet (see COMET). A spectroscope of twenty-five prisms was one of his inventions.

Donation of Constantine. See CONSTANTINE.

Donatists, a sect of North Africa which took its rise in 311, when, disapproving the election of Cæcilian as Bishop of Carthage, they elected Majorinus in his stead. On his death (313), Donatus Magnus succeeded, who is to be distinguished from another of their leaders, Donatus of Casæ Nigræ. Their main contention was that those who, during persecution, yielded up the sacred books (*traditores*) had fallen from grace,

and that the treatment of the 'lapsed' should be much severer than the Catholic Church demanded. Several church synods (of the lax, as they contended) condemned their unyielding Puritanism and their practice of rebaptising heretics. St Augustine diligently confuted them, and approved of their coercion by the Emperor Honorius. A synod at Carthage in 411 deprived them of civil rights; and in 415 their religious meetings were forbidden under pain of death. Along with the Catholics, they suffered heavily at the hands of the Vandals in the 5th century; and they were annihilated by the Saracens in the 7th.

See the works referred to under AUGUSTINE; Neander's History, vol. ii.; Monceaux, *Histoire Littéraire de l'Afrique Chrétienne* (vols. iv.-vi. 1912-22); also Optatus of Milevi, *De Schesmate Donatistarum adversus Parmenianum* (written about the end of the 4th century; ed. by Dupin, Paris, 1700); Walch, *Historie der Ketzereien*, vol. iv. (1768); Rabbeek, *Donatus und Augustinus* (Elberfeld, 1858); Volter, *Der Ursprung des Donatismus* (Freiburg, 1883); H. v. Soden, *Urkunden zur Entstehungsgeschichte des Donatismus* (1913).

Donative. See ADVOWSON.

Donatus, AELIUS, a well-known grammarian and commentator, who taught grammar and rhetoric at Rome about the middle of the 4th century, and was the instructor of St Jerome. He wrote treatises, *De Litteris*, *Syllabis*, *Pedibus et Tonis*, *De Octo Partibus Orationis*, and *De Barbarismo, Solecismo*, &c., which are collected by Keil in vols. iv. and v. of the *Grammatici Latini* (1864-65). These writings form together a pretty complete course of Latin grammar, and in the middle ages formed the only text-book used in the schools, so that Donat came, in the west of Europe, to be synonymous with grammar, or with the elements of any science. *The Donat into Religion* is the title of a book by an English bishop, and there was an old French proverb, *Les diables estoient encore à leur Donat* ('The devils were yet in their grammar'). The Latin grammar of Donatus has formed the groundwork of the elementary treatises on that subject to the present day. Donatus was one of the first books on which the art of printing by means of letters cut on wooden blocks was tried, and copies of these are reckoned among the greatest of bibliographical curiosities. The author also wrote a commentary on Terence, of which we possess only a part extending to five comedies, to be found in many editions of Terence.—From him must be carefully distinguished a later grammarian, TIBERIUS CLAUDIUS DONATUS (about 400), from whom we have a very worthless life of Virgil, prefixed to many editions of that poet, and fragments of a commentary on the *Aeneid*.

Donauwörth, an ancient town of Bavaria, situated at the confluence of the Wörnitz and the Danube, 25 miles NNW. of Augsburg by rail. It was formerly a free imperial city of considerable importance, but it has now sunk into an insignificant place of 5000 inhabitants. In 1606 the inhabitants, who had adopted the Reformed doctrines, attacked a Roman Catholic procession of the Host, for which in 1607 the town was placed under the ban of the empire, and severely punished in consequence. In the Thirty Years' War that followed it was twice stormed, by the Swedes and by the Bavarians. It is likewise associated with the name of Marlborough, who carried the intrenched camp of the French and Bavarians near here in 1704; and, on the 6th October 1805, the French, under Soult, obtained a victory here over the Austrians, under Mack.

Don Benito, a town of Spain, near the left bank of the Guadiana, 69 miles E. of Badajoz by rail, in a district rich in grain and fruit. Pop. about 21,000.

Don Carlos. See CARLOS.

Doncaster, a municipal borough in the West Riding of Yorkshire, and an important railway junction, on the right bank of the Don, and on the Great North Road, 33 miles S. of York, and 156 NNW. of London. The country around is flat, but beautiful. Fine old elms line the broad and level road from the town to the racecourse, about a mile to the south. Doncaster is well built, and the High Street is a mile long. The parish church of St George was rebuilt by Sir G. G. Scott, after destruction by fire, in 1853-58, at a cost of £43,128. Its noble tower is 170 feet high. Doncaster possesses an elegant market-hall, a guild-hall, a corn exchange, a wool-market, a cattle-market, an art gallery, a technical college, and a mansion-house. The borough free library was built in 1888-89. The water-works, constructed in 1880, were opened at a cost of £180,000, and since greatly extended. The town has manufactures of iron, brass, and agricultural machines. There are locomotive and carriage works. The agricultural trade is large; and there is a corn-market. Sinking of coal-mines has led to a great and rapid increase of population, met by an enlightened scheme of regional planning. Pop. (1851) 12,042; (1881) 21,130; (1911) 30,516; (1921) 54,052. Doncaster was the ancient *Danum*, and lay on the Roman road from York to Lincoln. Roman coins, urns, and a votive altar have been found. It was the *Dona Castræ* of the Saxons. The Saxon Northumbrian kings had a palace here. Doncaster was burned by lightning in 759, and frequently ravaged by the Danes. During the Civil War it was for some time the headquarters of the Earl of Manchester after the battle of Marston Moor. It has long been famous for its annual races, begun in 1703, and held a mile south-east of the town in the second week of September. Colonel St Leger, in 1776, founded stakes which have been yearly run for by the best horses in England. On an eminence 5 miles WSW. of Doncaster are the ruins of Conisborough Castle, the stronghold of Athelstan in Scott's *Ivanhoe*. A Norman-Saxon round tower, it is 37 feet in diameter and 86 feet high, with walls 15 feet thick, strengthened by square buttresses reaching the whole height. The door is arrived at by an external flight of 37 steps. See Tomlinson's *History of Doncaster* (1887).

Donders, FRANZ CORNELIUS (1818-1889), oculist and professor of physiology at Utrecht. See EYE.

Dondra Head. See CEYLON.

Donegal (*Dun-nan-G'al*, 'the fort of the stranger'), a seaport in the south of Donegal county, at the mouth of the Eske, on a shallow creek of Donegal Bay (a valuable fishing-ground, especially for herrings), 157 miles NW. of Dublin. It lies in a rich alluvial tract, surrounded on three sides by hills, behind which rise lofty picturesque mountains. Pop. (1851) 1580; (1911) 1104. Donegal exports corn and butter. A railway connects the town with Stranorlar, thence to the city and port of Londonderry. On the river is Donegal Castle, formerly belonging to the O'Donnells of Tyrconnel. The remains extant are those of the castle as rebuilt in 1601, on the former foundations, by Sir Basil Brooke. On the shore are the ruins of a Franciscan monastery, founded in 1474 by Hugh O'Donnel. Here was compiled the *Annals of the Four Masters* (q.v.). Near Donegal is a frequented sulphureo-chalybeate spa.

Donegal, a maritime county in Ulster province, washed by the Atlantic on the north and west. Its greatest length is 84 miles, its greatest breadth, 41; area, 1870 sq. m. The bold and rugged coast-line (166 miles long) is indented by

many deep bays and loughs; and there are numerous islands and islets off the coast, many of them inhabited. The surface generally is mountainous, moory, and boggy, with many small lakes and rivers, associated with endless fairy tales and traditions; here is excellent fishing. The highest hill, Erigal, rises 2462 feet, and several other hills exceed 2000 feet. The largest stream is the Foyle, running 16 miles north-east into Lough Foyle. Lough Derg is the largest lake. There is enormous wealth in beautiful granites, prior to 1889 almost unworked; and at Mountcharles there is a freestone unsurpassed by any other. White marble occurs at Dunlewy. The climate in most parts is moist, raw, and boisterous from violent west and north-west winds. There are manufactures of woollens, woisted stockings, worked muslins, and kelp (now greatly depreciated), and extensive fisheries. Successful efforts have been made by philanthropists to revive and extend home industries. Trade is chiefly through Londonderry. Pop. (1841) 296,448; (1851) 255,160; (1871) 218,334; (1881) 206,035; (1901) 173,625; (1911) 168,537—79 per cent. Catholics. Donegal is represented by six members in the Irish Free State parliament. The towns are small, the chief being Lifford, the county town, Ballyshannon, Letterkenny, Bundoran, Rathmelton, Donegal, Glenties, Raphoe, Ballybofey and Stranmillar (twin towns), and Killybegs. Substantial farmers and artisans occupy the low fertile tracts, the home of the 'planted' race. The population of the mountain districts, said to be the remnant of the old Irish sept or clans, has been much diminished by emigration. Till 1612, when James I. planted Ulster with English and Scottish settlers, the south part of Donegal was called Tyrconnel, and belonged to the O'Donnells, who, from the 12th century, were inaugurated as Princes of Tyrconnel on Doune Rock, near Kilmacrenan. Donegal has many ruins and traces of forts, of religious houses and castles, and of the palace of the North Irish kings on a hill near Lough Swilly. Near Derry is the coronation-stone of the ancient Irish kings. Donegal contains many memorials of St. Columba. Off Tory Isle, towards the entrance to Lough Swilly, which contains the remains of seven churches, two stone crosses, and a round tower, Warren, in 1798, captured a French fleet. Amongst the prisoners of war was the rebel, Theobald Wolfe Tone. St. Patrick's Purgatory, a famous place of pilgrimage, is on an isle in Lough Derg. See Stephen Gwynn's *Donegal and Antrim* (1899).

Donets, a river of Ukraine, flows SSE. to the Don. In its basin is the principal coalfield of south-eastern Europe.

Dongarpur (*Dungarpur*), a town of Rajputana, 340 miles N. of Bombay. It is the capital of a protected state of the same name, with an area of 1440 sq. m., and a pop. of 180,000, nearly 40 per cent. Hindus.

Dongola, New, called by its inhabitants Ordé, a town of Nubia, on the left bank of the Nile, above the third cataract, and about 750 miles S. of Cairo, with a citadel, and a population of about 10,000. Under Egyptian rule it became the capital of a province of the same name, embracing a district which had from early in the Christian era formed an independent kingdom. In the operations against the Mahdi, in 1884-85, the town was employed by the British as a base; in March 1886 the British forces were withdrawn, and Dongola fell into the possession of the Sudanese. Trade utterly decayed till after the reoccupation of the province in 1896 by the Anglo-Egyptian forces.—**OLD DONGOLA**, 75 miles SSE., on the right bank of the Nile, was the capital of the kingdom, but

was destroyed by the Mamelukes in 1820, and is now a mere village.

Donizetti, GAETANO, a famous Italian composer, was born at Bergamo, in Lombardy, 29th November 1797. He studied music first under Simon Mayr, the head of the then recently founded Conservatorio of Bergamo, and subsequently for three years at that of Bologna, where he had been preceded only a few years by Rossini. Though educated in the composition of the more scholarly church music, he at length determined to devote himself to the precarious career of a dramatic composer, and to carry this out, entered the military service of Austria. His first opera, *Enrico di Borgogna*, was produced in 1818 in Venice, with some success, and was followed by numerous others in rapid succession. *Zorade di Granata*, brought out in 1822 at Rome, gained him freedom from military service. But the first work which carried his fame beyond his own country was *Anna Bolena*, produced at Milan in 1830, when Pasta and Rubini took leading parts. On his first visit to Paris, in 1835, his *Marino Faliero*, met with little success, but immediately afterwards, *Lucia di Lammermoor*, which he wrote in six weeks, took the Neapolitan public by storm. In 1840 he returned to Paris, and produced, among others, *La Fille du Regiment*, at first with comparatively little effect, *Lucrezia Borgia*, and *La Favorita*, the last act of which is considered to be his masterpiece, and was written in from three to four hours. Leaving Paris, he visited Rome, Milan, and Vienna, returning to Paris in 1843, when were produced his comic opera *Don Pasquale*, and *Dom Sebastien*, whose gloomy theme almost precluded its success, and the anxious work upon which helped to bring on an attack of cerebral disease, from which he never completely recovered. His last opera, *Catarina Cornaro*, given at Naples in 1844, was a failure. Stricken by paralysis in that year, he fell into a condition of mental imbecility; and he returned to his native town in 1848, only to die (in April). His music was at first modelled after that of Rossini, and subsequently of Bellini, and is only second to theirs in the flow of beautiful and expressive melody, which is his principal source of effect, the orchestra being treated as little more than a 'big guitar.' Some of his concerted pieces, however, are very skilfully constructed, and he often anticipates the strong passion of Verdi. He had pre-eminent skill in suiting the voices for which he wrote, and penetration as to their capabilities. His nervousness as to the success of his works compelled him always to absent himself from the first three representations. His operas are over sixty in number; of these comparatively few are known here, but their melodious character is likely for long to preserve to them their great popularity.

Donjon, or DUNGEON, the principal tower or keep of a Castle (q.v.) or fortress. It was probably so called because, from its position, it dominated (Low Lat. *domnus*) or commanded the other parts of the fortress. From the circumstance that the lower or underground story of the donjon was used as a prison has come the modern meaning of the word.

Don Juan, a celebrated dramatic figure, the hero of a Spanish story, who stands as the southern realisation of the same subordination of the whole nature to self-gratification which under the colder northern skies has found expression in the conception of Faust. In Faust the development of the idea proceeds in the region of the intellectual as contrasted with the sensuous in Don Juan; and accordingly the former has found its highest expression in poetry, the latter in music. The ideal of the Don Juan legend is presented in the life of

a profligate who gives himself up so entirely to the gratification of sense, especially to the most powerful of all the impulses, that of love, that he acknowledges no higher consideration; and partly in wanton daring, partly to allay all uneasy misgiving, he then challenges that Spirit in which he disbelieves to demonstrate to him its existence in the only way he holds valid—through the senses.

This ideal career is aptly enough localised in one of the most luxurious cities of the once world-monarchy of the Saracens—Seville, and the characters wear the names of the ancient noble families of the place. The hero of the story, Don Juan, is described as a member of the celebrated family Tenorio, and is sometimes represented as living contemporary with Peter the Cruel, sometimes with Charles V. His chief aim is the seduction of the daughter of a governor of Seville, or of a nobleman of the family of the Ulloas. Being opposed by the father, he stabs him in a duel. He then forces his way into the family tomb of the murdered man, within the convent of San Francisco, causes a feast to be prepared there, and invites the statue which had been erected to his victim to be his guest. The stone guest appears at table as invited, compels Don Juan to follow him, and, the measure of his sins being full, delivers him over to hell. At a later period the legend came to be mixed up with the story of a similar profligate, Juan de Marañón, who had in like manner sold himself to the devil, but was at last converted, and died as a penitent monk in the odour of sanctity.

The story is probably a very old one. It is said that a poem with the like moral, *El Ateista Fulminado*, by an unknown author, was familiar in the monasteries long ere, in the first half of the 17th century, the legend of Don Juan was put into form by the monk Gabriel Tellez (Tirso de Molina), in *El Burlador de Sevilla y Convidado de Piedra*. This drama was transplanted to the Italian stage, and soon found its way to Paris, where numerous versions of it, among others Molière's *Don Juan, ou le Festin de Pierre* (first acted 1665), made their appearance. The latter provoked virulent criticism, and its full text was not printed for many years. It was put on the English stage by Shadwell under the title of *The Libertine* (1676). In the end of the 17th century, a new Spanish version of Tellez's play was prepared by Antonio de Zamora, and brought out on the stage. It is this version that forms the groundwork of the later Italian versions and of Mozart's opera. It was first put into an operatic form by Vincenzo Righini (1777); the text of Mozart's *Don Giovanni* was written by Lorenzo da Ponte (1787). Through this famous opera the story became popular all over Europe, and has since furnished a theme for numbers of poets, playwrights, and writers of romance. Alexander Dumas has a drama, *Don Juan de Marana*; Byron's *Don Juan* follows only the name, and character; and Prosper Mérimée's novel, *Les Âmes du Purgatoire*, is founded upon it. Mr G. B. Shaw has made paradoxical use of the story in *Man and Superman*. See De Bévotte, *La Légende de Don Juan*.

Donkey, a word of doubtful etymology, confined to slang dictionaries until so late as 1821, but now in current use as a synonym for Ass (q.v.). A *donkey-engine* is a small engine used for some subsidiary purpose, as for raising weights on board steam-vessels.

Donn, ROB. See MACKAY (ROBERT).

Donnay, MAURICE, French dramatist, born in Paris, 12th October 1859, was admitted to the Académie in 1907. His plays include *Amants* (1895) and *L'Autre Danger* (1902).

Donne, JOHN, a striking figure among English poets, was born in London in 1573. His mother was daughter of John Heywood, the epigrammatist, himself related to Sir Thomas More; his father, who belonged to a good old Welsh family, was a prosperous London ironmonger, who died early in 1576, leaving a widow and six children. Young Donne was brought up a Catholic, as his mother and her family were resolute adherents of that faith. In 1584 he was admitted at Hart Hall, Oxford, and here began his lifelong friendship with Sir Henry Wotton. There is documentary evidence for Izaak Walton's statement that he migrated to Cambridge, and for his taking his M.A. there. He appears to have spent some years in foreign travel, returning to be admitted at Lincoln's Inn in 1592. After a careful examination of the points at issue betwixt the Roman and Anglican churches, he joined the latter. In 1596 he accompanied the Cadiz expedition of Essex, and after his return from the Islands Voyage (1597), was appointed secretary to the lord-keeper, Sir Thomas Egerton, who set the highest value upon his services. Here Donne made the acquaintance of many of the chief men of his day, and wrote, without printing it, great part of his poetry. His wit, his personal beauty, and the charm of his personality brought him the warmest friendships, and the passionate love withal of Anne, the young daughter of Sir George More, brother of the lord-keeper's wife. The pair were secretly married about the close of 1601, the bride being but seventeen years old. Sir George More was violently enraged, at once caused Donne and his confidants to be committed to prison, and persuaded the lord-keeper into dismissing him from his office. The young couple were, however, befriended by the wife's cousin, Sir Francis Wootley, whose house at Pyrford was their home until 1604. Donne's knowledge of theology and of civil and canon law, and his general erudition, found him employment in 1605-8, when, living at Mitcham, he assisted Morton in refuting the arguments of Catholic political recusants. In 1610 his *Pseudo-Martyr* was an independent contribution to the same controversy. During this period also Donne wrote much verse. His *Divine Poems* he sent in 1607 to George Herbert's mother. The first poem to be printed was his famous elegy on Sir Robert Drury's daughter (1611), which procured him the friendship of a powerful patron, who carried Donne abroad with him for some months. It was at Paris that he saw pass twice before him the famous vision of his wife with a dead child in her arms, which was verified by a messenger twelve days later. (It was not John Donne but Sir Samuel Donne that Somerset employed in the Essex divorce.) His friend Morton, afterwards Bishop of Durham, had long urged Donne to take holy orders. At the king's solicitation he was at length ordained early in 1615. The king appointed him a royal chaplain, and fourteen country livings, it is said, were offered him within a year. He accepted in 1616 the rectory of Keynton, in Huntingdonshire, as well as that of Sevenoaks, keeping the latter until his death. As reader also at Lincoln's Inn, he quickly took the front rank among the preachers of the time, 'weeping,' says Izaak Walton, 'sometimes for his auditors, sometimes with them; always preaching to himself like an angel from a cloud, but in none; carrying some, as St Paul was, to heaven in holy raptures, and enticing others by a sacred art and courtship to amend their lives: here picturing a vice so as to make it ugly to those that practised it; and a virtue so as to make it beloved, even by those that loved it not; and all this with a most particular grace and an unexpressible addition of comeliness.' In the August of 1617 the death of his much-loved wife, the mother of his seven living

and five buried children, left him almost detached from the world, his soul 'elemented of nothing but sadness'; yet he continued to preach with saint-like fervour for ten years after his elevation to the deanery of St Paul's in 1621. He died 31st March 1631, and was buried in St Paul's, under a monument representing him wrapped in his shroud, which survived the Great Fire, as Cotton's poem conceitedly notes.

Ben Jonson told Drummond that he esteemed Donne 'the first poet in the world in some things, but that he would perish 'for not being understood'; and Dryden's judgment was that he was 'the greatest wit though not the best poet of our nation.' His poems were assiduously handed about among his contemporaries, with whom his influence was supreme, but Ben Jonson's prophecy threatened to come true. Many readers now again have eyes to discern poetry of rare quality, hidden like precious jewels in the midst of a dross of distressing obscurities of thought and imagery, elaborate ingenuity or rather fantasticality, and the most perversely far-fetched allusiveness, shallow philosophising, and laborious unrhythmical wit. His early amatory poems are lava-streams aglow with passion at white-heat, which cannot flow freely for the cinders that obstruct the current, although ever and anon revealing with startling unexpectedness the purity and intensity beneath. Peculiarly characteristic of Donne's poetry is that swift transition at will from the fleeting images of voluptuous pleasure to the abiding mystery of death. Amid much that is hardly poetical at all, Donne's saving grace as a poet is, in Mr Saintsbury's phrase, his 'fiery imagination shining in dark places, the magical illumination of obscure and shadowy thoughts with the lightning of fancy.'

Donne's poems were first collected in 1633. The editions of Dr Grosart, in his 'Fuller Worthies Library' (1872), of E. K. Chambers (1895), and of the Grolier Club (N.Y. 1895) have been superseded by the critical edition of Professor Grierson (1912). Selections from the sermons were edited by Pearsall Smith (1919), and Keynes (1923); his *Devotions* by Sparrow (1923). Alford's edition of his works in six volumes (1839) is far from satisfactory, but includes most of the sermons, of which Dr Jessopp accounts for no less than 130, written and preached within sixteen years, but its pious editor thought fit to leave out many of the earlier poems—Donne's real claim to a permanent place in English letters—although indeed he could claim for countenance the fact, as Walton tells us, that the dean himself in later life 'wished they had been abortive, or so short-lived that his own eyes had witnessed their funerals.' For his life see Walton's masterpiece (ed. Causton); Saintsbury, in Chambers's edition; Dr Jessopp in the *D.N.B.*, his monograph on Donne (mainly as churchman, 1897); Gosse's *Life and Letters of Donne* (2 vols. 1899). See also Ramsay, *Les doctrines médiévales chez Donne* (1920); Aronstein, *John Donne als Dichter* (1922); Studies by Fausset (1924), Mrs Simpson (1924), Praz (Italian, 1925); and Keynes's Bibliography (1914).

Donnybrook, now part of Dublin, at one time celebrated for a fair notorious for fighting, chartered by King John, and abolished in 1855.

Don Quixote. See CERVANTES.

Doo, GEORGE THOMAS, was born in the parish of Christ Church, Surrey, 6th January 1800. From an early age he practised as an engraver in London, and in 1825 he proceeded to Paris, where he studied under Suisse. He has made himself best known by his famous plates of 'Knox Preaching,' after Wilkie; of Eastlake's 'Italian Pilgrims coming in Sight of Rome'; by his exquisitely finished heads of women and children, after Lawrence; and by his engravings from Raffaele, Correggio, and others. His plate of the Calmady Children, titled 'Nature,' after Lawrence, produced in 1830, ranks as his masterpiece. In 1851 he was elected a Fellow of

the Royal Society; in 1857 an Academician. He was appointed chairman of the Engravings Committee of the London International Exhibition of 1862. About 1853–55 he painted in oils, his works of this class being mainly portraits. In 1864 he completed, after eight years' work, a large engraving of the 'Raising of Lazarus,' by Sebastian del Piombo, his last important work. He died 13th November 1886.

Doolittle, HILDA, known as 'H. D.', was born 10th September 1886, at Bethlehem, Pennsylvania, daughter and sister of two successive professors of astronomy in Pennsylvania University. Educated at a private school in West Philadelphia and Bryn Mawr College, she went to Europe in 1911. A visit to London developed into permanent residence. She was associated with Mr Ezra Pound in founding the Imagist school of poetry. In 1913 she married another Imagist poet, the Englishman Richard Aldington (born 1892). Her polished, classical art, applied to *vers libre*, made her the most outstanding of the Imagist group, whose ideals of the exact word, concentration, 'poetry that is hard and clear, never blurred or indefinite,' may be studied in her contributions to *Some Imagist Poets* (1915–16–17), and her own volumes, *Sea Garden* (1916) and *Tymen* (1921).

Doom, the old name given to the last judgment, and to those representations of it in churches which have a religious rather than an artistic object. Many of the dooms are executed in distemper. In the reign of Edward VI. most of them were washed over, or otherwise obliterated, as superstitious.

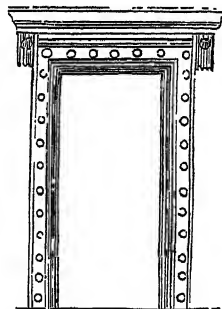

Doom Palm. See DUM PALM.

Doomsday Book. See DOMESDAY BOOK.

Doomster. See DEEMSTER.

Doon, a famous river of Scotland, rising in the south-east of Ayrshire in Loch Enoch. It runs north-west through Loch Doon, a gloomy sheet of water, 6 miles long by $\frac{3}{4}$ of a mile wide, surrounded by bare treeless mountains, past Dalmeilington, Burns's Monument, and Alloway Kirk, to join the Firth of Clyde 2 miles S. of Ayr. Its whole length is about 30 miles. On leaving Loch Doon the river flows through the picturesque Glen Ness, a rocky and beautifully wooded ravine. On an islet in the loch are the ruins of a castle. Burns has made this one of the world's most classic streams.

Door (O.E. *duru* and *dor*, related to Lat. *foris*, Gr. *thyra*). The doorway has always been regarded in all countries as a most important feature of any structure, and is therefore generally made more or less ornamental. The doorways of the Egyptian and Assyrian temples and palaces were of great size and magnificence, and were adorned with colossal statues. Those of the Greek and Roman temples were likewise large, and in the Roman were often the only aperture for the admission of light. Classic doorways are invariably surrounded with mouldings, which form the architrave. In the doorways of the Greeks the jambs generally incline inwards towards the top, and the lintel juts out at the ends—the mouldings being returned round it. Over the architrave there is frequently a frieze and cornice supported on trusses, which serve to give dignity and to protect the door from the weather. In the later Roman architecture,

Doorway of Erechtheum.

when the arch became an admitted element in the style, doorways were naturally treated with an arched head. The medieval styles derived from the Roman, such as the Byzantine, Romanesque, and Gothic, as well as the Saracenic, followed the same course, and the arched doorways were amongst their most characteristic features. In Romanesque architecture the doorway is always semicircular, and the arched head is enriched with mouldings springing from shafts in the jambs. The derivation of the mouldings and ornamentation of the arch and of the caps of the pillars is, in the earlier examples, clearly traceable to the classic prototypes; but the Roman details gradually give place to Teutonic features. The arched head is frequently filled in with a flat stone, so as to reduce the height of the doorway to that of the caps and give it a square head, which is a more convenient form for the door. The flat stone or

is often inclosed with square mouldings or labels, and in the Flamboyant and Tudor styles the four-centred arch and the ogee or reversed arch are commonly employed. Of course in all periods the mouldings and enrichments of the doorway are those of the time, and in late examples become very attenuated.

The doors themselves are generally of timber—the early ones having the frame covered on the outside with plain lining and ornamented with iron-work, the scrolls of which sometimes extended over the whole surface. In later examples the doors were usually panelled, and often partly covered with tracery—especially in Perpendicular work. Doors of chambers were also sometimes beautifully carved with bas-reliefs in the panels. Doors were occasionally made of metal, the bronze gates of the Baptistery of Florence and Pisa Cathedral being well-known examples.

Doora. See DURRA.

Doornboom (*Acacia horrida*), a common tree in the wastes of South Africa. The name ('thorn-tree') given to it by the Dutch colonists, and the botanical specific name, are due to the number and sharpness of its spines. It seldom much exceeds 30 feet in height, but its timber is hard and tough, and is much used for house-carpentry, &c. See ACACIA.

Doppler, CHRISTIAN (1803-53), born at Salzburg, became professor of physics at Vienna (1851). 'Doppler's principle' explains the shift of lines in the Spectrum (q.v.) of a star approaching or withdrawing from the observer; and likewise the drop in pitch of (say) a locomotive whistle as it passes the hearer. See STARS.

Doquet. See DOCKET.

Dor. See MONT-DORÉ-LES-BAINS.

Dor, a negro people of Central Africa, also called Bongo, between 6° and 8° N. lat., and bordering on the Dinka and Niam-Niam stocks.

Dor. See LUNG-BEETLE.

Dora, SISTER. See PATISON.

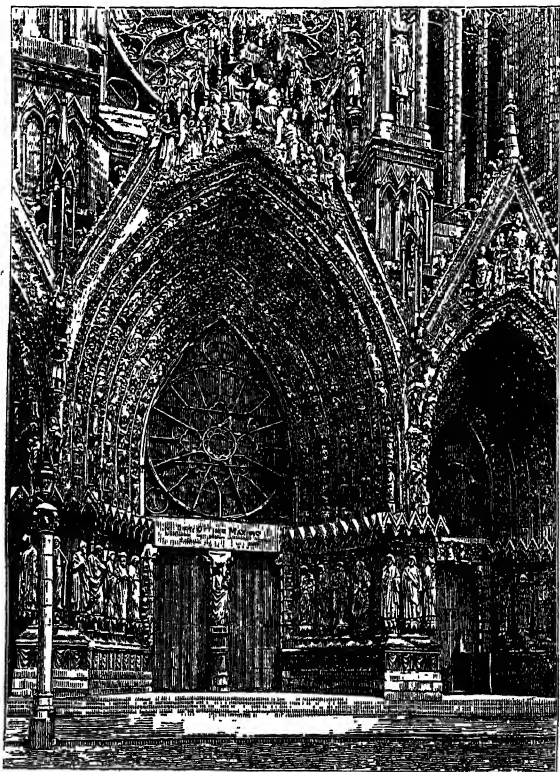

Dora, or DOR (now *Tantura*), a great Phœnician city on the coast of Palestine, 8 miles N. of Cæsarea, with remains of the Hyksos period.

Dora d'Istria. See GHKA.

Dorak-el-Atek, a town of Persia, in the province of Arabistan, situated in a marshy plain on the Jerrahi, 55 miles E. of Basra. Pop. 8000.

It is the seat of the sheikh of Dorakistan or Kaban.

Doran, JOHN, Ph.D., born in London 11th March 1807, brought out a melodrama, *Justice, or the Venetian Jew*, at the Surrey Theatre in 1824. His *Sketches and Reminiscences* appeared in 1828, and in 1835 a *History of Reading*. In 1854 he published *Habits and Men*, followed by *Table Traits, Queens of England of the House of Hanover* (1855), *Monarchs retired from Business* (1857), *History of Court Fools* (1858), *The Princes of Wales* (1860), *Memoir of Queen Adelaide* (1861), *Their Majesties' Servants* (1864, a history of the stage from Betterton to Kean; new ed. by Lowe, 1887). *A Lady of the Last Century* (1873, an account of Mrs Montagu), *Mann and Manners* (1876, the letters of Sir Horace Mann to Horace Walpole), *London in Jacobite Times* (1877), *Memories of Our Great Towns* (1878), and *In*

Portal, Reims Cathedral.

tympa-num is usually ornamented with sculpture representing our Saviour, or some Scripture subject. When the doorway was wide it was generally divided into two openings with a central pilaster.

In the various Gothic styles the doorway is invariably a prominent object. This is especially the case in French architecture, in which the portals of the cathedrals and churches are of great size, and richly ornamented with large sculptured figures and bas-reliefs. One of the most notable of these is the majestic deeply-recessed triple portal of Reims Cathedral. Those of the English edifices, although highly ornamented, are not on so great a scale. A favourite decoration of all periods is a series of niches filled with figures carried round the jambs and archway. In early Gothic the doorways are pointed and surmounted with a gable, in the later periods the pointed arch

and *About Drury Lane* (1885). Dr Doran was repeatedly acting-editor of the *Athenæum*; edited the *Church and State Gazette* (1841-52); and at his death, 25th January 1878, was editor of *Notes and Queries*.

Dorat. See DAURAT.

Dorcas Society, the name given to an association of ladies who make or provide clothes for necessitous families. The name is taken from Acts, ix 39: 'And all the widows stood by him weeping, and showing the coats and garments which Dorcas made while she was with them.'

Dorchester, a municipal borough, the county town of Dorsetshire, on the Frome, 8 miles N. of Weymouth, and 110 by rail (by road 119) WSW. or London. Till 1867 it returned two members to parliament, till 1885 one. It has a trade in ale and beer, a large agricultural market of cattle and cereals, and sends much butter to London. The free grammar-school founded in 1579 has been rebuilt and reorganised. The county museum is rich in geological specimens found in the county, including the fore-paddle of a *Pleiosaurus* 6 feet 3 inches in length, discovered at Kimmeridge. The museum also contains a fine piece of Roman pavement (almost perfect) found on the site of the old Dorchester Castle, when the county prison was built in 1793. Pop. (1841) 3249; (1921) 9554. Dorchester was the Roman *Durnovaria* or *Durnum*, a walled town with a fosse, and a chief Roman British station. Part of the wall, 6 feet thick, still remains, and is carefully preserved. Near Dorchester are the remains of the most perfect Roman amphitheatre in England, 218 by 163 feet, and 30 feet deep, the seats rising from the arena, cut in the chalk, and capable of holding 13,000 spectators. There is also a Roman camp with a ditch and high vallum. Near Dorchester is a large British station with three earthen ramparts (one 60 feet high), a mile and a half in circuit, and pierced by intricate passages. Its name, 'Maiden Castle,' has nothing to do with a castle for defending maidens, or strong enough to be defended by girls; but is the Celtic-British *maiden*, 'hill fort.' (There are four or five other 'Maiden Castles' in England and Scotland.) In March 1645 Cromwell held the town as his headquarters with 4000 men, and in 1685 Judge Jeffreys held his 'bloody assize' here, when 292 received sentence of death as being implicated in Monmouth's rebellion. In the porch of St Peter's Church the Rev. John White is buried. A leading Puritan, and known as 'the Patriarch of Dorchester,' he was the projector of the colony of Massachusetts, in New England, but did not join the expedition. He was a member of the Westminster Assembly and minister in Dorchester, with a short interruption from 1606 till his death in 1648. The original edition of Case's *Guide to Dorchester* was written by the Dorchester pastoral poet, William Barnes (q.v.); but Dorchester is better known as the home of Thomas Hardy (q.v.), and the centre of his Wessex.

Dorchester, now an unimportant village of Oxfordshire, 9 miles SE. of Oxford, was the seat of the Mercian bishops from the 7th century till 1073, when the see was transferred to Lincoln. The Augustinian abbey church (mainly 13th century; restored) is lavishly ornamented, and has an interesting 'Jesse' window.

Dorchester, formerly a separate town of Massachusetts, 4 miles S. of Boston, was in 1869 annexed to that city. The fortification of Dorchester Heights by Washington, in March 1776, compelled the British to evacuate Boston.

Dorchester, GUY CARLETON, 1ST BARON (1724-1808), was governor of Quebec, 1766-70 (acting), 1775-77, 1786-91, and 1793-96, and defended that city against the Americans, whom he defeated at Lake Champlain, 1776. In 1782-83 he was British commander-in-chief in America.

Dordogne, a department in the south-west of France, formed of the ancient Guenness district of Périgord, with small portions of Agenais, Limousin, and Angoumois. Area, 3530 sq. m. Pop. (1861) 501,687; (1921) 396,742. The department derives its name from the river Dordogne, which, after a course of 305 miles, 185 of them navigable, unites with the Garonne to form the large estuary of the Gironde. The climate is mild and healthy, except in the west. The soil is generally poor, the surface for the most part hilly, and covered with forests or, more frequently, heath and under-wood; but here and there is a valley of extraordinary beauty and fertility, inclosed with hills, the sides of which are usually clothed with vineyards. Among the most noted productions are the truffles of Périgord. The iron industry is the most important in the department. Other manufactures are paper, woollens, chemical manures, and glassware, and there is an active trade in wine, brandy, oil, fruits, walnuts, hams, and cattle. Dordogne has five arrondissements—Bergerac, Nontron, Périgueux, Ribéac, and Sarlat. The capital is Périgueux. The Dordogne basin is rich in palæolithic remains.

Dordrecht. See DORT.

Doré, GUSTAVE, painter and illustrator of books, was born at Strasburg, 6th January 1833. In 1845 he came to Paris, at the age of fifteen began to exhibit landscape subjects in pen and ink in the Salon; in 1848 he became a contributor to the *Journal pour rire*, and he was afterwards on the staff of the *Journal pour tous*. He first made his mark by his illustrations to Rabelais (1854), to Sue's *Wandering Jew*, and to Balzac's *Contes Drolatiques* (1856), which fully displayed his facility of execution and his fantastic power of invention. These were followed by innumerable illustrated editions of other well-known works; in 1861 by Dante's *Inferno*, in 1863 by the *Contes* of Perrault, in 1863 by *Don Quixote*, in 1868 by the *Purgatorio* and *Paradiso* of Dante, in 1865-66 by the Bible, in 1866 by *Paradise Lost*, in 1867-68 by Tennyson's *Idylls of the King*, in 1867 by La Fontaine's *Fables*, and many other series of designs, the latest of which became poor and feeble in character, the artist having exhausted himself by incessant over-production. Doré was also ambitious of ranking as an historical painter, and he executed much in colour. He himself said that between 1850 and 1870 he earned £280,000 by his pencil. Among the earliest of his pictures are 'The Battle of the Alma,' and 'The Battle of Inkermann,' shown in the Salons of 1855 and 1857. Two of his most successful oil-pictures are 'Paolo and Francesca da Rimini' (1863), and 'The Neophyte' (1868). His 'Tobit and the Angel' is in the Luxembourg Gallery. For many years there was a Doré gallery in London, filled with his works, which were more popular there than in France, among which the enormous canvases of 'Christ leaving the Prætorium' (1867-72) and 'Christ's Entry into Jerusalem' figured prominently. He is, however, seen at his best in his book-illustrations, for his colouring is unreal and wanting in delicacy and harmoniousness, and he had no technical mastery over the methods of oil-painting. He is most successful in subjects of a weirdly humorous or grotesque class; but he fails completely in the religious scenes which he so often set himself to depict. He displayed

some ability as a sculptor. He exhibited a colossal vase decorated with figures at the Exposition Universelle, Paris, 1878; and at the time of his death, 23d January 1883, he was engaged upon a monument to the elder Dumas. See *Lives* by Miss Roosevelt (Lond. 1886) and B. Jerrold (1891).

Doria, ANDREA, a Genoese of noble family, and admiral of the Emperor Charles V., was born of comparatively poor parents, in November 1466 or 1468, at Oneglia, where his ancestors had been princes for centuries. The Dorias had long held a foremost place in the republic; they had again and again led the fleets of Genoa to victory over Pisa and Venice. Andrea took to the profession of arms at the age of nineteen, when he entered the pope's guards, in which his uncle held a command. On the accession of Alexander VI. he took service with the Duke of Urbino (whose son he subsequently saved from the Borgias), and then with Alfonso of Naples, on whose departure Doria went to the Holy Land till the troubles should be over. On his return he joined the Prince of Sinigaglia in resisting the Spaniards, who were then triumphing over Italy. Doria dreaded the extinction of the Genoese state before the overmastering tide of imperial conquest, and devoted himself with all his energy to restoring the ancient naval renown of his countrymen. He returned to Genoa in 1503, his military exploits procuring him immediate employment; in 1513 he was appointed commander of the galleys of the republic, and soon his name was a terror to the Turkish corsairs, who were now beginning their ravages in the Mediterranean. In 1519, with six ships, he captured thirteen of their gallees off Pianosa; but his connection with Genoa was suddenly broken by a revolution, which in 1522 restored the faction of the Adorni, who favoured the imperial interest. Doria transferred his allegiance to Francis I., as much to save his country from Charles V. as to serve his personal ambition. The French fleet rode the seas supreme so long as Doria commanded, and Charles V. sustained several defeats. Doria blockaded Genoa, turned out the Adorni, and proclaimed the independence of the republic, where he was hailed as the liberator of his country. Once more he changed sides in 1529, and fearing the predominance of Francis, or thinking himself slighted, went over with his twenty private galleys to Charles V. The imperial fleet soon felt his influence, and now it was not France but the empire that held the seas. Genoa welcomed him as its father: he peacefully entered the city, and, refusing the title of sovereign, established a form of popular government, with a strong aristocratic element, which lasted to the end of the republic. The emperor gave him the order of the Golden Fleece and the principship of Melfi. Doria's career now became one long duel with his great rival the corsair Khair-ed-din Barbarossa (q.v.). In 1531 the Genoese admiral descended upon the latter's stronghold at Shershel on the Barbary coast, but lost many of his men without holding the place. In 1532 he sailed with a great fleet to the Ionian waters, and took Coron and Patras from the Turks; one of his most brilliant feats was the revictalling of Coron in the teeth of the Turkish navy in the following spring. (See *Jurien de la Gravière, Doria et Barberousse.*) In 1535 he accompanied Charles V. to Tunis, where his galleys took a prominent part in the bombardment of the Goletta forts and the destruction of Barbarossa's fleet, but failed to capture the corsair himself. Barbarossa now commanded, as Kapudan Pasha, the navy of Turkey; collecting a fleet of 150 sail, he ravaged the islands about Greece, which chiefly belonged to Venice; and in 1538, meeting the combined fleets of the emperor, the pope, and the Venetians, off Prevesa, he offered battle. Doria's

conduct in manœuvring out of range, not without the loss of his heavier sailing-vessels, was severely criticised, and Barbarossa came off decisively with the honours of war. Thenceforward, for a quarter of a century, the Turks were masters of the Mediterranean, and the power of Venice was crippled. Doria's expedition to Algiers with Charles V. in 1541 was a disastrous failure, and in 1560 he suffered a terrible reverse at Jerba, near Tunis, at the hands of one of Barbarossa's pupils, the renegade Ochiali (Uluj Ali). On the whole, Doria was out-matched by the corsairs. His later years had been disturbed by the conspiracy of Fieschi, and stained by the savage revenge he took upon those who were associated with the murder of his favourite nephew Gianettino. Prince Andrea Doria died at Genoa without issue, 25th November 1560, in his ninety-third or ninety-fifth year. He was the idol of his people, and the honoured counsellor of Charles V. and his son Philip, a born adventurer, personally very valorous, a man of great heart, a great admiral, but a greater soldier. See Richer, *Vie d'Andrea Doria*; Sandore; Capelloni: Brantôme; Celesia, *Conspiracy of Fieschi*.

Dorians, one of the great Hellenic races who took their name from the mythical Dorus, the son of Hellen, who settled in Doris; but Herodotus says that in the time of King Deucalion they inhabited the district Phthiotis; and in the time of Dorus, the son of Hellen, the country called Histiaeotis, at the foot of Ossa and Olympus. But the statement of Apollodorus is more probable, according to which they would appear to have occupied the whole country along the northern shore of the Corinthian Gulf. Indeed, Doris Proper was far too small and insignificant a district to furnish a sufficient number of men for a victorious invasion of the Peloponnesus. It is doubtful whether the descent of Dorus from Deucalion and the assumption of Herodotus that the Dorians alone were true Hellenes, is based upon any real tradition. Plato in the *Laws* suggests that the Dorians were Achæans, who returned from the siege of Troy under a leader named Doriens. The views of Herodotus, Apollodorus, and Plato, however, must be read in the light of the discoveries of the archaeologist in the 20th century. The immigration of the Dorians into Greece, like that of the Æolians and Ionians, belongs to the Mycenaean period; and by the Dorians Mycenaean civilisation was brought into Greece. Of old they were known as Achæans; and that fact is readily explained if we assume that Thessaly was the point from which they dispersed over Greece. The first district populated by them in the Peloponnesus thus acquired the name of Achæa. This is confirmed by the fact that the Achæan dialect is close akin to that of Phocis and Locris on the one side, and that of Argolis on the other. The name of the Dorians, like the names of the Ionians and Æolians, probably originated in Asia Minor, and thence travelled to Crete and the Peloponnesus. For the Dorian mode, see HARMONY, PLAINSONG.

Doric Order. The oldest and simplest of the three orders of Greek architecture. See COLUMN, GREEK ARCHITECTURE.

Doris, a small mountainous district of ancient Hellas, between Phocis, Ætolia, Locris, and Thessalia, was the home of the Dorians (q.v.). It is now a part of the modern government of Phocis.—Doris was also the name of a district in Asia Minor on the coasts of Caria, inhabited by colonists from the Peloponnesus.

Doris, a genus of gasteropod molluscs in the sub-order Nudibranchiata, the type of a family called Doridæ, and sometimes popularly Sea-

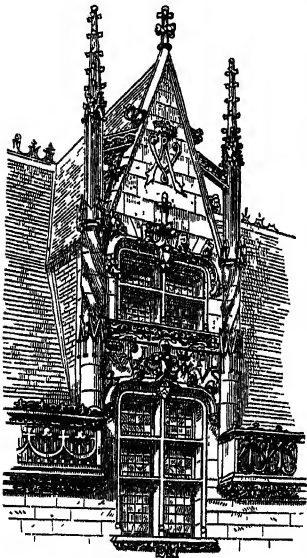

lemons. The body has an elongated oval form, a flat ventral and more or less arched dorsal surface, a whitish, yellowish, or brownish colour, and usually a warty skin. Two retractile club-shaped tentacles on the back of the head, and feathery respiratory processes, sometimes retractile, round the anus, are also marked characteristics. There is no distinct mantle or adult-shell, but the skin of the back is slightly broadened out over head and 'foot,' and limy particles occur in the skin. The radula is broad, and many-toothed. Numerous species occur in British and other seas, but more abundantly in the southern hemisphere. Some of them attain a considerable size. Few of them inhabit deep water. They crawl on rocks, seaweeds, &c., where they are often left by the tide; or swim in a reversed position, the foot, made concave by muscular action, serving to buoy them up. Some of them are pretty and interesting inmates of the aquarium.

Doris: a, gills.

Dorislaus, ISAAC, born in 1595 at Alkmaar, in Holland, came about 1627 to England, where for some time he held a history lectureship at Cambridge, and afterwards was appointed judge-advocate. He sided with the parliament, helped to bring Charles I. to his doom, and in the spring of 1649 was sent back to his native land to bring about an alliance between the republic and England. He had just reached the Hague, when on 12th May he was assassinated by a Scottish colonel and eleven other royalist conspirators. His body was brought to England, and buried in Westminster Abbey, whence it was ejected in 1661.

Dorking, an old-fashioned market-town of Surrey (with a suffragan bishop since 1904), stands in a picturesque valley near the base of Box Hill (590 feet), 24 miles SSW. of London. Its church, with a spire 210 feet high, is a memorial to Bishop Wilbeforce, who met his death riding over the Downs near Dorking (1873). Deepdene, the lovely seat of 'Anastasi' Hope, where Beaconsfield wrote *Coningsby*, is close to the town. Flint Cottage (near Burford Bridge) was George Meredith's. The battle of Dorking, vividly described by General Chesney in 1871, is happily still unfought. Pop. (1851) 3490; (1881) 6328; (1921) 8058. — For Dorking breed of Fowls, see POULTRY.

Dormer Window.

(From the Château de Josselin, Brittany, end of the 15th century.)

DORMER WINDOW, is a window placed in a small gable rising out of a sloping roof, often made use of

for the purpose of enlarging and lighting the attic or garret-rooms of modern houses. It is also popularly known as a storm-window. *Dormers* do not appear to have been in use before the middle of the 14th century. After that date they were greatly employed, especially in the later domestic Gothic edifices. Those of the Hôtel de Ville at Rouen are amongst the most splendid examples.

Dormitory (Fr. *dormitoire*, from Lat. *dormire*, 'to sleep'), a sleeping apartment in a monastery, or other similar establishment. Dormitories are usually of considerable size, sometimes having a range of cells or 'cubicles' partitioned off on each side. In schools, the dormitories are bedrooms.

Dormouse (of doubtful etymology), a common name applicable to any member of the rodent family Myoxidæ, but especially used with reference to various species of *Myoxus* and *Muscardinus*. The dormice may be described as arboreal rodents, squirrel-like in form and habit, but are classified in the mouse-like or Myomorph section of the order Rodentia. They have long hairy tails, short fore-limbs, tolerably large eyes, and large, almost naked ears. The head is narrow, the upper lip cleft, the body compressed, the thumb rudimentary, the molars with more or less marked transverse enamel folds. They live among trees and bushes, are principally twilight animals, and as their name (sleeping-mice) implies, hibernate. In their distribution they are confined to the Old World, in its palaearctic and Ethiopian regions. The family includes four genera—*Myoxus*, *Muscardinus*, *Eliomys*, and *Graphiurus*. Remains of dormice are found in Miocene strata.

The Common Dormouse (*Muscardinus avellanarius*) is a pretty little animal, about three inches in length, not including the bushy tail, which is almost as long as the body. The general colour is a beautiful tawny yellow, but there is white on throat and breast. It is widely distributed from Britain and Scandinavia to Tuscany and Turkey, and is especially fond of hazel-copses. It feeds on nuts, seeds, berries, buds, &c., grows very fat in autumn, sleeps intermittently through the winter in a round grassy nest a little above the ground. It breeds in spring, but, in some cases at least, also in autumn. It is the only British dormouse.—The Loir or Fat Dormouse (*Myoxus glis*)

Dormouse (*Muscardinus avellanarius*).

is about twice the size of the common dormouse, and has the hairs of the tail in two rows, as in squirrels. It is ashen-gray, sometimes brownish above and white below. In its distribution the loir is restricted to the south. The favourite haunts are in oak and beech woods. It is very fond of fruit, and is said even to become carnivorous. The Roman epicures esteemed its flesh, and fattened it in their *gliraria*. It is still cooked by the Italians.

Dormant Vitality and cognate states are treated in the articles on Anæsthesia, Coma, Desiccation, Hibernation, Latent Life, Mud-fish, Rotatoria, Suspended Animation, Trance.

Dormer, or

—The Garden Dormouse (*Eliomys nitela*) is a destructive thief, smaller and more active than the last, common in Central and Western Europe. It is justly persecuted for the damage it does in orchards, where it is said to destroy much more than it eats.—In the genus *Graphiurus* the tail is shorter, and ends in a brush-like tuft of hairs. The molar teeth are very small, and the cross enamel folds are hardly developed. See RODENT.

Dornbirn, a town in the Austrian land of Vorarlberg, on a small affluent of the Lake of Constance, 7 miles S. of Bregenz by rail, with important cotton-factories, and large iron and brass foundries, brick and lime kilns, and sawmills. Pop. of the four villages which form the town, 14,000.

Dorner, ISAAC AUGUST, a great Protestant theologian, born 20th June 1809, near Tuttlingen, in Württemberg, studied theology and philosophy at Tübingen, next travelled in England and Holland, and had already filled chairs at Tübingen, Kiel, Königsberg, Bonn, and Göttingen, when in 1861 he was called to be professor at Berlin. There he died, 8th July 1884. Dorner for many years took an active share in the administration of the church, but was saved from ever becoming a partisan by a singularly fair and well-balanced mind, and by his strong grasp of a real historical spirit, which he did much to impress on modern German theology. His greatest work is the *History of the Development of the Doctrine of the Person of Christ* (Eng. trans. 5 vols. 1861-63). Besides this, his *History of Protestant Theology* (1867), his *System of Christian Doctrine* (1880-81), and his *Christian Ethics* (1885), through their English translations, became handbooks in England and America.

Dornick, a species of figured linen, named from Tournay or Doornik, in Flanders. The 'mystery,' introduced into England, was long confined by law to inhabitants of Norwich and Pulham.

Dornoch, the county town of Sutherland, 7 miles SSE. of the Mound station, and 40 NNE. of Inverness, stands near the entrance to Dornoch Firth, which, running 22 miles inland, separates Sutherland from Ross-shire. It has splendid golf-links, a tower of the old bishop's palace, handsome county buildings, and the former cathedral of the see of Caithness (1245), which, burned in 1570, was rebuilt for the parish church in 1837, and contains a statue by Chantrey of the first Duke of Sutherland. The last witch burned in Scotland suffered at Dornoch in 1727. It was made a royal burgh in 1628, and with Wick and four other towns returned one member to parliament till 1918. Pop. (1861) 647; (1881) 497; (1891) 514; (1901) 624; (1921) 768.

Dorohoi (*Dorogoi*), a town of Rumania, in the extreme north of Moldavia, on the Shishia, 70 miles NW. of Jassy; pop. 16,000, nearly half Jews.

Dorothea (OF ZELL). See the articles GEORGE I., KÖNIGSMARK.

Dorp, till 1889 a town of Rheinland, now incorporated with Solingen (q.v.).

Dorpat, or DERPT (Esthonian *Tartu*, Russian *Yur'ieff*), a town of Esthonia, on the Embach, here crossed by a fine granite bridge, 165 miles SW. of Petrograd. It consists of a town proper, with two suburbs. The Domberg Hill, on the right bank of the river, was during the middle ages occupied by the citadel, cathedral, and bishop's palace, on whose site now rise an observatory, the university library, schools of anatomy, &c., with tasteful gardens and promenades; and close by are the other university buildings and the town-house. The university, founded in 1632 by Gustavus Adolphus, was re-established by Alexander I. in

1802. Since May 1887 it had been thoroughly Russianised, the final reorganisation of the law faculty taking effect in 1889; in 1919 it was Esthonised. It has seven faculties, and about 3000 students. There is a notable botanical garden. Dorpat was a Hanse town in the 14th and 15th centuries, and was alternately captured by Swedes, Poles, and Russians until 1704, and remained in Russia's possession till 1918. Thrice was a great part of the town levelled to the ground; on the last occasion, in 1708, it was practically destroyed. But both from these calamities and from the great fires of 1763 and 1775 it recovered, and it is the handsomest and best-built town in the republic. It possesses large printing establishments, breweries, sawmills, manufactories of cigars, tiles, and musical instruments, and has a considerable trade in wood, corn, and flax. Dorpat had long been a centre and hearth of Germanism in the Baltic regions, in spite of official measures of Russification. Pop. 50,000, very largely German.

Dörpfeld, WILHELM, archaeologist, born at Barmen in 1855, excavated at Olympia, was secretary and professor in the German Archaeological Institute at Athens, and was Schliemann's collaborator and successor at Troy.

D'Orsay, ALFRED GUILLAUME GABRIEL, COUNT, the last of the 'dandies,' was born in Paris, 4th September 1801. The son of General D'Orsay, a distinguished French soldier, he early entered the service of Louis XVIII. as a lieutenant in the Garde du Corps. It was while his regiment was stationed at Valence on the Rhone in 1822 that he made the acquaintance of Lady Blessington (q.v.), who was travelling on the Continent with her husband. An intimacy soon sprang up between the brilliant countess and the still more brilliant Frenchman, and D'Orsay resigned his commission, and attached himself to the Blessingtons, with whom he travelled in Italy and elsewhere, until 1827, when as if to 'regularise' his irregular position in the family, he was married to Lady Harriet Gardiner, Lord Blessington's fifteen-year-old daughter by a former wife—a marriage which, as may be supposed, turned out unhappily. In 1829 Lord Blessington died, and D'Orsay separated formally from his wife, and took up his residence at Lady Blessington's, in Mayfair first, and then at Kensington, where for twenty years they defied the conventions in the midst of a society of authors, artists, and men of fashion. D'Orsay was not only one of the handsomest men of his time, well bred, well dressed, the mirror of fashion and the mould of form; but he was an accomplished painter and sculptor, an author of no mean power, an excellent talker, and a genial companion. An intimate friend and constant supporter of Louis Napoleon, he naturally looked for a position when the exile became prince-president and the host a bankrupt; but the office for which he was so admirably fitted, that of Director of Fine Arts in Paris, was conferred upon him only a few days before his death on 4th August 1852.

Dorse, a small variety of Cod (q.v.).

Dorset, EARL OF. See SACKVILLE.

Dorsetshire, or DORSET, a maritime county in the south of England, on the English Channel, between Hampshire on the E. and Devonshire on the W. Its greatest length is 58 miles; greatest breadth, 40; average, 21; and area, 978 sq. m., or 625,612 acres, of which a third is arable, a ninth waste, and the rest pasture. The coast-line is 75 miles long, with fine cliffs and headlands. St Alban's Head (354 feet high) and Golden Cap (619 feet high) are among the highest coast points between Dover and the Land's End. Off Swanage was fought the first naval battle in British history,

that of Alfred the Great against the Danes in 876, when 120 of the Danish fleet were driven on the rocks and destroyed. About midway in the coast-line is Portland, an island, so called, but connected with the mainland by a remarkable formation known as Chesil Bank (q.v.), which, extending 10 miles towards Abbotsbury, incloses a narrow tidal inlet, called the Fleet, with decoy ponds, and a fine swannery of about 1000 swans at Abbotsbury. There is a dangerous sea called 'The Race,' about a mile to the south of Portland, formed by the meeting of the tides. There are two lighthouses at the end of Portland, also one of more recent erection at Anvil Point, near Swanage. Portland (q.v.) contains a large Borstal institution (long a convict establishment), a fine breakwater, harbour of refuge, a naval hospital, and extensive fortifications. Chalk downs run along the south coast, and through the middle of the county nearly from east to west. The highest point is Pilsden Pen (934 feet). The chief rivers are the Stour and the Frome. Geologically, Dorsetshire consists of strata of plastic clay, chalk, oolite, lias, with some weald and greensand. Remains of colossal reptiles have been found at Lyme Regis and near Swanage. The chief mineral productions are the celebrated Purbeck and Portland building-stones, and white china and pipe clays. At Swanage is found the celebrated Purbeck marble, seen in many English cathedrals. The climate is mild. The chalk hills or downs are covered with short fine pasture, on which countless numbers of Southdown sheep are fed. The soil is chiefly sand, gravel, clay, and chalk. Dorsetshire is mainly a pastoral county, producing sheep, cattle, cheese, and butter; but some wheat, barley, hemp, linseed, hops, &c. are raised. Sainfoin is grown on the chalk hills. There are small manufactures of linen, silk, woollens, flax, hemp, buttons, stockings, and ale and cider. Pop. (1841) 175,054; (1871) 195,537; (1881) 190,979; (1921) 228,258. Since 1885 the county sends four members to Parliament, the towns of Dorchester, Biddport, Poole, Weymouth and Melcombe Regis, Shaftesbury, and Wareham, formerly sending up ten members, ceased to be separate constituencies in that year. Dorchester has prehistoric and Roman remains, as stone circles, barrows, camps, an amphitheatre, and three Roman stations; and a chambered long barrow, known as (Iray Mare and Colts, near Gorwell. There are some remains of forty abbacies, priories, hospitals, &c. The ruins of Corfe Castle (q.v.), a seat of the Saxon kings of Wessex, are among the grandest in England. The scenery of Dorsetshire has been rendered familiar to many outside the county by the works of Barnes and Hardy. See Hutchins's *History of Dorset* (1774; 3d ed. 1861-73), Worth's *Dorsetshire* (1882), Moule's *Old Dorset* (1894), *The Victoria History*, and books cited in C. H. Mayo's *Bibliotheca Dorsetiensis* (1885).

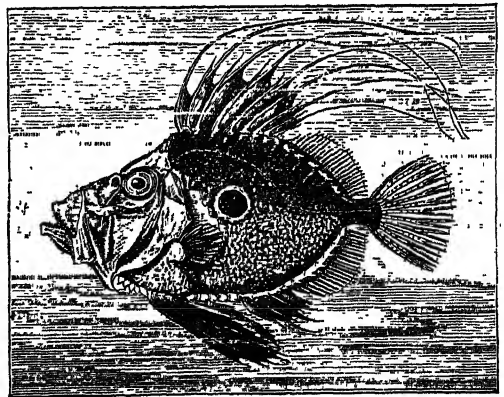

Dorstenia. See CONTRAYERVA.

Dort, or DORDRECHT, a town of the Netherlands, in the province of South Holland, is situated on an island formed by the Maas, 10 miles SE. of Rotterdam by rail. An inundation in 1421, in which upwards of 70 villages were destroyed and 100,000 people drowned, separated the site upon which Dort stands from the mainland. It is one of the oldest, as in the middle ages it was the richest of the trading towns of Holland; and its trade is still considerable. Among its chief buildings are a Gothic cathedral (1363) and a handsome town-hall (1339). The town is traversed by canals, and large ships as well as gigantic wood-rafts which come down the Rhine from the Black Forest and Switzerland, are accommodated in its roomy harbour. Close by are a large number

of shipyards, corn and saw mills, and manufactures of ironwares, gas-meters, safes, locks, tinplate, motors, and other machinery. Pop. 54,000. Dort was founded in 1013. Here in 1572, the States of Holland, after the revolt from Spain, held their first assembly; and sat from 13th November 1618 to 19th May 1619, the conclave of Protestant divines known as the Synod of Dort, which condemned the doctrines of Arminius as heretical, and affirmed those of Calvin (see ARMINIUS). The house in which the synod sat has been demolished. Dort is the birthplace of the brothers De Witt, of Cuyper, and Ary Scheffer; to the last a statue was erected in the market-place in 1862.

Dortmund, the most important town of Westphalia, lies in the fertile Hellweg plain, near the Emscher, 74 miles NNE. of Cologne by rail. In 1846 its inhabitants numbered only 8732, and it owes its subsequent increase to the development of the Westphalian coal-mines. It is the headquarters of the mining authorities of Westphalia, and an important railway centre; and it has numerous iron and steel works, bridge-building works, and manufactures of mining material, machines, safes, cement, chocolate, tobacco, cycles, and furniture. In the town there are also numerous breweries, most of the beer being exported. The history of Dortmund goes back into the earliest middle-age traditions, figuring from the 8th century under the names of *Therolmanns*, *Theromanni*, *Trutmanni*, and *Dornpunde*. Subsequently it became a free Hanse town, but was ceded to Prussia in 1815 at the Congress of Vienna. It still possesses several old churches, and the meeting-place of the Vehmgericht (q.v.) is still pointed out; but since the walls were removed in 1863, the general aspect of the town has become quite modern. Pop. (1890) 89,663; (1919) 295,026.

Dory (*Zeus*), a genus of bony fishes in the mackerel family (Scombridae). The body is high and laterally compressed; the scales are very small or absent; the dorsal fin bears nine or ten spines; and there are bony plates at the root of the dorsal and anal fins, and on the ventral surface. The best known of the six species is the John Dory (*Z. faber*), found in the Mediterranean and off the

John Dory (*Zeus faber*).

Atlantic coasts of Europe. The name is possibly a corruption of *jaune dorée* (yellow-gilt), which well describes the prevalent yellowish colour and metallic sheen. According, however, to Skeat, the 'John' is merely the ordinary English name (cf. 'jack-snipe'). The colour is sometimes olive-brown, and there are two dark patches on the sides, which are (as in the haddock) fancifully interpreted as the marks of the apostle Peter's

fingers. Others have referred the marks to St Christopher. The John Dory disputes with the Climæra the title of 'king of the herrings.' It follows rather than leads shoals of herring and other fishes. The body is greatly compressed, and the numerous bony plates bear spines; the head is very large, and the gape wide; the teeth are feeble; the membrane between the long spines of the dorsal fin is prolonged into beautiful waving filaments. The dory is on the whole sluggish, but feeds voraciously on pilchards, breams, and other fishes, &c. It has been known to attain a length of 22 inches, and a weight of 18 lb. It has for long been greatly esteemed for the table. The other species are widely distributed; one is known in Australian seas. On the British coasts, other fishes, such as the Silver Haddock, are erroneously called by the name.

Dôsch, an Arabic word meaning 'treading,' denotes a remarkable ceremony, which, until its suppression in 1884, used to take place in Cairo annually on the feast of the prophet's birth, in the third month of the Mohammedan year. A party of dervishes of the Sa'di order, to the number of a hundred or more, lay down on their faces, side by side, with their arms doubled under their foreheads. A dozen more ran along upon their comrades' prostrate backs, beating drums, and shouting 'Allah!' Then the sheikh of the order, mounted on a good-sized horse, which ambled with a fine action, rode along upon the line of bodies, from whom audible prayers could be heard proceeding. The horse trod upon each man twice, yet, as the sheikh passed on, those behind rose up apparently unhurt. This has however been disputed, and evidence has been produced of considerable injury inflicted by the iron-shod hoofs. It was in consequence of this that the Khedive Tewfik suppressed this singular religious rite. See Lane, *Modern Egyptians*, xxiv.; Butler, *Court Life in Egypt*.

Dositheus was a Jewish heresiarch of the 1st century A.D., who insisted on a painfully rigorous observance of the Sabbath, and died of excessive fasting.—There was also a grammarian of this name in the 4th century, who wrote a Latin grammar for Greek boys.

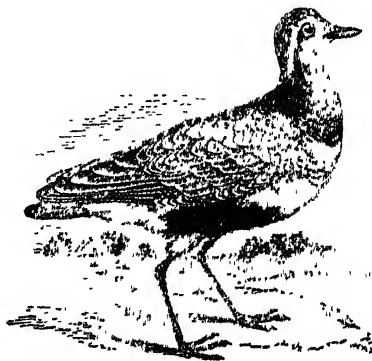

Dost Mohammed. See AFGHANISTAN.

Dostoevsky, or DOSTOEVSKI, FEODOR MIKHAILOVITCH (1818–81), a Russian novelist, was born at Moscow, passed through the imperial school of engineers, and after a short trial of the army adopted literature as a profession. His first story, *Poor Folk* (1846; Eng. trans. 1894), which painted with unsparing truth the condition of the peasantry and the more hopeless state of the poor in the cities, at once drew attention to him and to his views of social conditions. At this period he became involved in the Communist plots of Petiochevsky, and in 1849 was condemned to death, commuted on the scaffold to penal servitude in Siberia, followed by military service in the ranks for life. After four years' imprisonment and six years' exile he was permitted to return to St Petersburg, where in 1860 he published an account of his prison life. His masterpiece, *Crime and Punishment*, which appeared in 1866, is one of the most powerful and affecting works in the whole range of modern fiction, realistic; strong in its grasp of character and its unflinching analysis of motive; unique in a magnetic sympathy that impels the reader to identify himself with characters often sordid or repulsive. Some critics account *The Brothers Karamazoff* (though unfinished) his greatest work. Another great work is *The Idiot*, whose hero is, like its author, an epileptic. Dostoevsky in middle life was harassed by the rapacity of relatives and creditors of a brother whose debts he took upon himself.

Latterly he developed Slavophil patriotism, partly reactionary.

A translation of the novels by Mrs Constance Garnett began to appear in 1912. Messrs Middleton Murry and Koteliensky translated *Pages from the Journal of an Author* (1916) and *Letters and Reminiscences* (1923); Miss E. C. Mayne, *Letters to his Family and Friends* (1914). See studies by Brandes (1889), Hoffmann (1899), J. A. T. Lloyd (1912), Middleton Murry (1916, 1923), Lavrin (1920); and Lives by Soloviev (1891; trans. 1916), and his daughter Aimée (trans. 1921).

Dotterel (*Eudromias morinellus*), a kind of plover, known in Britain as a bird of passage, though sometimes breeding at high elevations on the hills. It is widely distributed in Europe, in the north in summer, in the south in winter. A nearly related species (*E. asiatica*) has a similar distribution in Asia. The dotterel is about nine inches and a half in its whole length. In summer plumage, the upper parts are of a brownish-gray colour, the feathers edged with deep red; the cheeks, throat, and a band above the eyes, white; the breast bright rust-colour, with a white patch on the upper part of it, bounded above by a blackish

Dotterel (*Eudromias morinellus*).

line; a conspicuous black patch on the middle of the belly; some of the tail-feathers tipped with white. The winter plumage is much less definite. The bird is proverbial for its tame stupidity; but this is due to its unacquaintance with man's evil intent. It becomes shy and watchful after a little experience. It is much esteemed for the table, and well known in the London market. The name Ring Dotterel is applied to a sandplover frequenting the shore (*Egialites hiaticula*), which seems to serve as sentinel to dunlins and sandpipers. Both *Eudromias* and *Egialites* were formerly included along with the plovers proper (*Charadrius*). See PLOVER.

Douai (Roman *Duacum*), a town in the French department of Nord, on the river Scarpe, 21 miles S. of Lille. It is one of the chief military towns in the north of France, was strongly fortified, contains an important arsenal, a cannon foundry, and a school of artillery. It was burned in the Great War (1918). The principal buildings are the churches, the hôtel-de-ville, the public library, the museum, hospital, and artillery barracks. The manufactures include linen thread, leather, bottles, iron machinery; and there is an active trade in corn, seed, and linen. Pop. (1921) 34,131. During the middle ages Douai was a constant bone of contention between the Flemish counts and the French rulers. It passed with the rest of Flanders under the dominion of Spain, but was taken by Louis XIV. in 1667. It was captured by the Duke of Marlborough in June 1710, but on the withdrawal of the

allies was re-occupied by the French, who were confirmed in their possession of it at the Peace of Utrecht.

For more than two centuries Douai was the rallying-point of Roman Catholic exiles from Great Britain. There were several educational and religious houses established in the town in connection with the English and Scottish mission. The English College, the parent and model of similar institutions at Rome, Lisbon, and elsewhere on the Continent, was founded in 1568, the tenth year of Elizabeth's reign, by William, afterwards Cardinal Allen (q.v.), as a house of studies for the English clergy abroad, and as a seminary or nursery for ecclesiastics destined for the English mission. The college was affiliated to the Douai University, which had been founded in 1562 by King Philip II, in whose dominion the town then was. Allen's foundation was supported by pensions from the Spanish king and from the pope. The first batch of four missionaries was sent into England in 1574. Political disturbances led to the migration of the college, in 1578, from Douai to Reims, where it was under the protection of the king of France and the Guises. A colony of students from Reims in 1578 formed the nucleus of a second college at Rome, under the government of the Jesuits; and the two establishments together sent into England, before 1586, about 250 priests, of whom no less than 60 suffered death at the hands of the executioner. The most flourishing period of Allen's college was that of its sojourn at Reims (1578-93), though before the return to Douai it had begun notably to decline. On Allen's appointment as cardinal in 1587, and his consequent removal to Rome, the college was torn with internal dissensions, studies were neglected, and scandals ensued. It was at Reims that the English Roman Catholic version of the Bible was begun by Dr Gregory Martin, with the assistance of Allen, Dr Bristow, and others. The New Testament was printed at Reims in 1582. The Old Testament, also translated by Martin, with notes by Dr Worthington, was not completed and published until 1610 at Douai, and hence the version as a whole is commonly known as the Douai Bible (see BIBLE). Notwithstanding its many troubles the college was able to boast that before its dissolution at the French Revolution it had produced more than 30 bishops and 169 writers, while 160 of its alumni had given their lives on the gallows for the papal cause. An interesting list of the English Catholic books printed at Douai will be found at Duthillou's *Bibliographie Douaiesienne*. It is said that valuable documents from the college archives were made into cartridges by the French revolutionary soldiers. Some few of the manuscripts, however, have found their way into the public library of the town, and others are preserved in the archives of the Roman Catholic archbishopric of Westminster. Among the latter is the greater portion of the college Registers or Diaries, the first two parts of which were published in 1878, the third, fourth, and fifth in 1911.

The members were expelled from the college, and the property confiscated by the French government, 12th October 1793. A small portion of the property which remained unsold was restored to Mr Daniel, the last president, by an ordinance of the French king, dated 25th January 1816. But further claims for compensation under the terms of the treaty of peace were resisted by the British commissioners on the ground that the college was established for objects directly opposed to British law, and was to be regarded as a French rather than an English corporation. This decision on appeal was confirmed by a judgment of Lord Gifford in the Privy-council, 25th November 1825.

There is no ground for the common story that the sum claimed was expended by the government in paying off the debts incurred by the Prince of Wales in adorning the Brighton Pavilion. The college buildings were converted into artillery barracks known as Les Grands Anglais.

On their return to England, the masters and students of the college, among whom was Lingard, the historian, laid the foundations of a similar college at Crook Hall, in 1808 transferred to Ushaw, near Durham. Another college at Old Hall, Essex, was established by refugees partly from Douai, and partly from St Omer.

There was also established at Douai a Scots College. This seminary, originally founded at Pont-à-Mousson, in Lorraine, by Dr James Cheyne of Abovne, in 1576, was assisted by a pension from Queen Mary. After her death it was reduced to great straits, and could count only seven members. In 1594 it moved to Douai, thence to Louvain, and finally was once more transferred to Douai in 1608. Clement VIII. placed it under the administration of the Jesuits. Hippolyte Curle, the son of Mary's secretary, made over to the college by deed of gift a large sum of money, providing, however, that in case of his country's return to the Roman religion, the foundation should be transferred to St Andrews University. Curle became the second rector of the college, and died in 1638. The college was closed in 1793 by the French government, and turned into a prison. It eventually became the mother house of a congregation of nuns devoted to education, called Les Dames de la Sainte Union. The register of the Scots College came into the hands of Sir Maxwell Witham of Kirkconnell (see Hist. MSS. Commission, Report V. and App.), and was printed by the New Spalding Club (1906).

The English Franciscan friars established at Douai a house of their own, which produced some men of reputation for learning and piety. The English Benedictines did the same. There was also a college of Irish ecclesiastics in the town. The Benedictines returned after the Revolution to their old buildings, or to a portion of them. They alone retained a footing at Douai till 1908, when they removed to Woolhampton, near Reading, in consequence of the Associations Law.

A curious tract on the history of Allen's foundation was written by the Rev. Hugh Tootle, alias Charles Dodd, under the title of *The History of the English College at Douay*, by R. C., Chaplain to an English Regiment that marched in upon its surrendering to the Allies (Lond. 1713). The *First and Second Douay Diaries* of the English College, Douai, with an historical introduction by T. F. Knox (1878), were edited by the Fathers of the London Oratory, the later diaries by Burton and Williams (1911). Full accounts of the later history will be found in Gillow's *Haydock Papers* (1888). Compare the Abbé Dancoisne's *Histoire des Etablissements religieux britanniques fondés à Douai avant la Révolution Française*, and *Le Collège Anglais pendant la Révolution*, by the same author.

Douarnenez, a port in the French department of Finistère, on the Bay of Douarnenez, 8 miles NW. of Quimper by rail. It is important for the sardine-fishery, and has a pop. of 12,000.

Double (Ger. *doppelgänger*), a kind of apparition, a person's own likeness appearing and usually admonishing the beholder of approaching death, a wraith; or simply implying *bilocation*, when the same person is supposed to be seen by others in two places at once. See APPARITION and the works there cited; also Lambertini's *De Beatificatione*; and for a kind of double consciousness, see PERSONALITY. Double is playfully applied to either of

two persons so closely resembling as to be mistaken for each other.

Double Bass (Ital. *contrabasso* or *violone*), the largest stringed instrument of the violin species. Originally it had only three strings, tuned to A, D, G of the bass stave; but as much of the music written for it goes down to E and F below this range, a fourth string is now generally added tuned to E below the bass stave. Playing the fundamental base on which the harmony rests, it is an indispensable part of an orchestra, though it was only in the 19th century that special parts were written for it. Formerly its part was simply to double, an octave below, the ordinary base of the harmony, played by some other instrument, or sung by the bass voice. From this probably arose its name of double bass. Though a powerful and essential orchestral instrument, it, on account of its rough tone and difficulty of management, has not, except in very exceptional circumstances, been used as a solo instrument. Domenico Dragonetti (1755-1846) was an unrivalled performer on the double bass: Koussevitski a modern virtuoso.

Double Flowers. See FLOWERS.

Doubling the Cube was one of three famous problems which were discussed by the early Greek geometers, the other two being the trisection of an angle and the squaring of the circle. There are several theories as to how the duplication problem originated; the statements of the ancients on this point being quite unsatisfactory. The legendary origin, told by Eratosthenes in a letter to Ptolemy Energetes, was that King Minos, when he learned that the dimensions of a tomb for his son Glaucus were to be 100 feet each way, complained of them as too small, and commanded the tomb to be doubled and the cubical form to be retained. Another legend, also mentioned by Eratosthenes, was that certain Delians, in obedience to an oracle, attempted to double one of the altars, and finding a difficulty in doing so, consulted the geometers who were with Plato at the academy. The duplication of the cube hence came to be called the Delian problem.

In whatever manner the problem originated, it was much older than Plato's time, and the first contribution to the solution of it was made by Hippocrates of Chios. He showed that the solution could be obtained if between two straight lines, the greater of which was double the less, there could be inserted two mean proportionals; and in this modified form the problem was ever afterwards attacked. Solutions were discovered by various geometers, Archytas, Menæchmus, Eratosthenes, Nicomedes, and others, and an account of them will be found in the commentary of Eutocius on Archimedes's treatise *Of the Sphere and Cylinder*. This account is translated into English in the *Proceedings of the Edinburgh Mathematical Society*, vol. iv. pp. 2-17. It is often and inaccurately stated, even in mathematical books, that the duplication of the cube cannot be effected by geometry. The truth is that it cannot be effected by elementary plane geometry, where straight lines and circles are the only lines that are employed. By the use of the conic sections or several other geometrical curves, as well as by mechanical contrivances, the solution can be obtained without much difficulty. Nowadays the problem possesses only an historical interest, except for those persons whom De Morgan calls paradoxers.

Doublings, the heraldic term for the linings of robes or mantles, or of the mantlings of achievements.

Doubleon (Span. *doblón*, 'double'), a gold piece, originally double the value of a pistole, formerly coined in Spain and Spanish America.

Prior to 1848 it was worth 64s. 8d. The Doblón de Isabel, coined in 1848, was till 1868 equivalent to 20s. 8d.

Doubs, a department of France, on the eastern frontier, adjoining Switzerland, has an area of 2010 sq. m. Pop. (1876) 306,094; (1886) 310,963; (1901) 296,957; (1921) 285,022. It is traversed by the Doubs (270 miles long), a tributary of the Saône, and is separated, on the NW., from the department of Haute Saône by the Ognon (120 miles), also a tributary of the Saône. The surface is hilly, especially in the SE., where the Jura Mountains reach a height of 4600 feet. The climate is moist and more rigorous than in most similar latitudes. The uplands are sparsely inhabited, but the population of the fertile river valleys is very thick. Agriculture has been notably advanced since 1870; swamps have been drained and waste lands reclaimed, and three-fourths of the entire area is now cultivated or under wood. Wheat and oats are the chief cereals, but the vine and fig-tree also thrive well; and the pasturage is excellent, and rears good breeds of horses and goats. In the valley, great quantities of butter and cheese are produced. Mines of iron are worked, and the manufactures include iron-ware, clocks, glass, paper, and pottery. Doubs is divided into the four arrondissements of Besançon, Baume-les-Dames, Montbéliard, and Pontarlier. The capital is Besançon.

Douce, FRANCIS, an eccentric and learned antiquary, born in London in 1757, whose easy circumstances allowed him from an early age to give himself entirely to his favourite studies. He was some time keeper of the MSS. in the British Museum, and died 30th March 1834, bequeathing his splendid collection of books, MSS., prints, and coins to the Bodleian; his curiosities to Sir Samuel R. Meyrick; and his letters and commonplace-books to the British Museum, in a chest not to be opened till 1900. When opened they were found of little interest. The most valuable of his works were his *Illustrations of Shakespeare* (2 vols. 1807) and *The Dance of Death* (1833). He contributed to the *Archæologia* and *Gentleman's Magazine*, edited two books for the Roxburghe Club (1822 and 1824), and assisted in Scott's *Sir Tristram*, J. T. Smith's *Vagabondiana* (1817), and the edition of Warton's *History of English Poetry* issued in 1824.

Doughty, CHARLES MONTAGU, traveller, prose-writer, and poet, was born at Theberton Hall in Suffolk in 1843, and studied at Gonville and Caius, Cambridge. In 1875 began his two years' journeying in north-western and central Arabia, from Damascus to Hayil, Aneysa, and Jidda—two years of endurance and courage, of perils and the closest of observation, out of which slowly grew his great book. *Travels in Arabia Deserta* (1888) was for long little known; but the few who had access to it—for it was a rare book, not reprinted till 1921—knew it to be more than a classic of travel: it is a classic of prose literature. Artificial it may be in style, and laborious, it is yet austere. In his later works, poetic dramas and epics—*Dawn in Britain* (1906), *Adam Cast Forth* (1908), *The Cliffs* (1909), *The Clouds* (1912), *The Titans* (1916), *Mansoul* (1920; revised 1923)—the artificiality and archaism are more marked. Disciple though he is of Spenser, his verse is hard and compact as rock, strange, uncouth, and gigantic as Stonehenge.

Douglas, the modern capital and principal seaport of the Isle of Man, lies on the margin of a highly picturesque bay, on the east side of the island, 75 miles NW. of Liverpool, 46 W. of Barrow, and 94 NE. of Dublin. From the excellence of the sea-bathing, and its central position, it has

become highly popular as a watering-place. The old town, standing on the south-western edge of the bay, consists of narrow tortuous streets, and presents a vivid contrast to the handsome modern terraces and villas which occupy the rising ground beyond, and the ground facing the north of the bay. The street and charming promenade following the line of the bay is one of its most agreeable features. Conspicuous in the centre of the crescent of the bay stands Castle Mona. The picturesque Tower of Refuge, on a dangerous rock in the southern area of the bay, called Conister, was erected in 1833 for shipwrecked mariners, by Sir William Hillary, who, during his residence at Douglas, founded the Royal National Lifeboat Institution. Pop. (1851) 9880; (1881) 15,719; (1911) 22,192; (1921) 20,192.

Douglas, a small town of Lanarkshire, on Douglas Water, 11 miles SSW. of Lanark. It has decayed from its former importance, though coal, lime, and sandstone are worked in the valley. Of the old kirk of St Bride, the burial-place of the Douglasses till 1761, only the choir and a spire remain. Modern Douglas Castle, a seat of the Earl of Home, is nearly a mile from the town. It is a poor successor to Scott's 'Castle Dangerous,' now represented by little more than a tower.—The scene of the 'Douglas tragedy' is Blackhouse Tower, on the Douglas Burn in Yarrow parish, Selkirkshire.

Douglas, THE FAMILY OF. A legend of the 16th century told how, in the year 770, a Scottish king, whose ranks had been broken by the fierce onset of a Lord of the Isles, saw the tide of battle suddenly turned by an unknown chief; how, when the victory was won, the monarch asked where was his deliverer; how the answer ran in Erse, *Sholto Du-glas* ('Behold that dark-gray man'); and how the warrior was rewarded with that Clydesdale valley which, taking from him its name of Douglas, gave surname to his descendants. This fable has long ceased to be believed. Equal discredit has fallen on the theory which the laborious Chalmers advanced in the *Caledonia*, that the Douglasses sprang from a Fleming of the name of Theobald, who, between the years 1147 and 1164, had a grant of lands on the Douglas Water from the Abbot of Kelso. What was boasted of the Douglasses by their historian in 1644 still holds true: 'We do not know them in the fountain, but in the stream; not in the root, but in the stem; for we know not who was the first mean man that did by his virtue raise himself above the vulgar.' It was thought likely, in the beginning of the 15th century, that the Douglasses and the Murrays had come of the same stock, and in this old and not improbable conjecture all that is known on the subject must still be summed up.

William of Douglas, the first of the family who appears in record, was so called, doubtless, from the wild pastoral dale which he possessed. He is found witnessing charters by the king and the Bishop of Glasgow between 1175 and 1213. He was either the brother or the brother-in-law of Sir Freskin of Murray, and had six sons, of whom Archibald, or Erkenbald, was his heir, and Brice rose to be Bishop of Moray. Sir Archibald is a witness to charters between 1190 and 1232, and attained the rank of knighthood. Sir William of Douglas, apparently the son of Sir Archibald, figures in record from 1240 to 1273. His second son, distinguished in the family traditions as William the Hardy, spoiled the monks of Melrose, and deforced the king's officers in the execution of a judgment in favour of his mother. He was the first man of mark who joined Wallace in the rising against the English in 1297. It appears that he possessed lands in one English, and in seven

Scottish counties—Northumberland, Berwick, Edinburgh, Fife, Lanark, Ayr, Dumfries, and Wigton.

The history of his son, the Good Sir James of Douglas, is familiar to every one, as Bruce's greatest captain in the long War of Independence (see BRUCE). The hero of seventy fights, he is said to have won them all but thirteen, leaving the name of 'the Black Douglas'—so he was called from his swarthy complexion—as a word of fear by which English mothers stilled their children. He was slain in Andalusia, in 1330, on his way to the Holy Land with the heart of his royal master. The 'bloody heart' in the Douglas arms commemorates Bruce's dying bequest to him. His son William fell at Halidon Hill; and the next Lord of Douglas, Hugh, brother of Lord James, and a canon of Glasgow, made over the now great domains of the family in 1342 to his nephew Sir William.

EARLS OF DOUGLAS.—The Douglasses had since the time of William the Hardy held the title of Lords of Douglas; but in 1358, Sir William of Douglas, who had fought at Poitiers, was made Earl of Douglas, and by marriage became Earl of Mar. In 1371 he disputed the succession to the Scottish crown with Robert II., claiming as a descendant of the Baliols and Comyns. He died in 1384. His son James, second Earl of Douglas and Mar, the conqueror of Hotspur, fell at Otterburn in 1388; and as he left no legitimate issue, the direct male line of William the Hardy and the Good Sir James now came to an end. His aunt had married for her second husband one of her brother's esquires, James of Sandilands, and through her Lord Torphichen, whose barony was a creation of Queen Mary in 1564, is now the heir general and representative at common law of the House of Douglas.

The earldom of Douglas, meanwhile, was bestowed on an illegitimate son of the Good Sir James—Archibald, Lord of Galloway, surnamed the Grim. By his marriage with the heiress of Bothwell, he added that fair barony to the Douglas domains; and having married his only daughter to the heir-apparent of the Scottish crown, and his eldest son to the eldest daughter of the Scottish king, he died in 1401. His son and successor, Archibald, fourth Earl of Douglas, was, from his many misfortunes in battle, surnamed 'The Tineman,'—i.e. the loser. At Homildon, in 1402, he was wounded in five places, lost an eye, and was taken prisoner by Hotspur. Next year, at Shrewsbury, he felled the English king to the earth, but was again wounded and taken prisoner. Repairing to France, he was there made Duke of Touraine, and fell at Verneuil in 1424. He was succeeded by his son Archibald, who distinguished himself in the French wars, and dying in 1439, was buried in the church of Douglas, where his tomb yet remains, inscribed with his high titles of 'Duke of Touraine, Earl of Douglas and of Longueville, Lord of Galloway, Wigton, and Annandale, Lieutenant of the King of Scots.' His son and successor, William, a boy of sixteen, is said to have kept a thousand horsemen in his train, to have created knights, and to have affected the pomp of parliaments in his baronial courts. His power and possessions made him an object of fear to the Scottish crown; and, having been decoyed into the castle of Edinburgh by the crafty and unscrupulous Crichton, he was, after a hasty trial, beheaded, along with his brother, within the walls of that castle, in 1440. It was before him that the black bull's head was presented at table, in 'token of death.' His Scottish earldom was bestowed on his grand-uncle (the second son of Archibald the Grim), James, surnamed the Gross, who in 1437 had been made Earl of Avondale. His son William was, for a time, all-powerful with King James II., who made him lieutenant-general of the realm; but afterwards losing the royal favour, he seems to

have entered into a confederacy against the king, by whom he was killed in Stirling Castle in 1452. Leaving no child, he was succeeded by his brother James, who in 1454 made open war against King James II., as the murderer of his brother and kinsman (the sixth and eighth Earls of Douglas). The issue seemed doubtful for a time, but the Hamiltons and others being gained over to the king's side, Douglas fled to England. The struggle was still maintained by his brothers. They were defeated at Arkinholm (where Langholm now stands), in May 1455; and the earldom of Douglas came to an end by forfeiture, after an existence of ninety-eight years, during which it had been held by no fewer than nine lords. The last earl lived many years in England, leagued himself in 1484 with the exiled Duke of Albany, was defeated and taken prisoner at Lochmaben, and died in the abbey of Lindores in April or June 1488. So ended the elder illegitimate line of the Douglasses.

EARLS OF ANGUS.—Meanwhile a younger and illegitimate branch had been rising to great power. William, first Earl of Douglas, while securing the earldom of Mar, also secured the affections of the young widow of his wife's brother, Margaret Stewart, Countess of Angus and Mar. The issue of this amour was a son, George, who in 1389 had a grant of his mother's earldom of Angus. George, fourth Earl of Angus, took part with the king against the Douglasses in 1454; his loyalty was rewarded by a grant of their old inheritance of Douglasdale and other lands; and so, in the phrase of the time, 'the Red Douglas put down the Black.' The 'Great Earl of Douglas' died in 1462, being succeeded by his son Archibald, surnamed Bell-the-Cat (see JAMES III.), who filled the highest offices in the state, and added largely to the family possessions. He was succeeded by his grandson, Archibald, who in 1514 married the queen-dowager of Scotland, Margaret, sister of Henry VIII. of England, and widow of James IV. of Scotland. The fruit of this marriage was a daughter, Margaret, who, marrying the Earl of Lennox, became the mother of Henry, Lord Darnley, the husband of Queen Mary, and father of James VI. The Earl of Angus had for a time supreme power in Scotland, but in 1528, the young king, James V., escaped from his hands, and sentence of forfeiture was passed against Angus and his kinsmen. On James's death in 1542, Angus was restored to his estates and honours. He was succeeded by his nephew, David, whose son, Archibald, the 'Good Earl,' died without male issue, and the earldom passed to a collateral branch. William Douglas of Glenberrie became ninth Earl of Angus.

MARQUISES AND DUKE OF DOUGLAS, AND LORDS DOUGLAS.—William, eleventh Earl of Angus, his grandson, was created Marquis of Douglas in 1633. The third Marquis was created Duke of Douglas in 1703, and died childless in 1761, when his dukedom became extinct, and his marquisate devolved on the Duke of Hamilton, as descended in the male line from William, Earl of Selkirk, third son of the first Marquis of Douglas. His grace's sister, Lady Jane Douglas, born in 1698, and married in 1746 to Sir John Stewart of Grandtully, was said to have given birth at Paris to twin sons in 1748. One of them died in 1753; the other in 1761 was served heir of entail and provision general to the Duke of Douglas. An attempt was made to reduce his service, on the ground that he was not the child of Lady Jane Douglas; but the House of Lords, in 1771, settled the famous *Douglas Cause* by giving final judgment in his favour. He was made a British peer in 1790, by the title of Baron Douglas of Douglas Castle, which became extinct on the death of his son James, fourth Lord Douglas, in 1857, when the estates devolved on the first Lord

Douglas's grand-daughter, the Countess of Home.

EARLS OF MORTON.—Sir Andrew of Douglas, who appears in record in 1248, was apparently a younger son of Sir Archibald, or Eikenbald, of Douglas, the second chief of the house. His great-grandson (?), Sir William of Douglas of Liddesdale, the Knight of Liddesdale—as he was called by his contemporaries, who regarded him as 'the flower of chivalry'—was assassinated in 1353 by his kinsman, William, first Earl of Douglas. The grandson of his nephew, the scholarly and princely Sir James of Douglas of Dalkeith, married a daughter of King James I., and in 1458 was created Earl of Morton. His grandson, the third earl, dying without male issue in 1553, the earldom devolved on his youngest daughter's husband, the Regent Morton—James Douglas, great-grandson of Archibald Bell-the-Cat (see MORTON). Aberdour and some other old domains of the family still remain with his successor, the Earl of Morton, who, there is every reason to believe, descends legitimately in the male line from William of Douglas, the great progenitor of the race in the 12th century.

James, second Earl of Douglas and Mar—the hero of Otterburn—had an illegitimate son, Sir William Douglas of Drumlanrig, whose descendants were created Viscounts of Drumlanrig in 1628, Earls of Queensberry in 1633, Marquises of Queensberry in 1681, Dukes of Queensberry in 1683, Earls of March in 1697, and Earls of Solway in 1706. On the death of the fourth Duke of Queensberry in 1810, that title went to the Duke of Buccleuch; the title of Marquis of Queensberry went to the heir male of the family, Sir Charles Douglas of Kelhead; and the title of Earl of March went to the Earl of Wemyss.

In 1646 the third son of the first Marquis of Douglas was created Earl of Selkirk. In 1651 the eldest son of the same marquis was created Earl of Ormond, and in 1661 Earl of Forfar. In 1675 the fourth son of the same marquis was created Earl of Dumbarton. In 1641 the second son of the tenth Earl of Angus was created Lord Mordlington. In 1633 Sir Robert Douglas of Spott, a descendant of the Morton family, was created Viscount of Belhaven. Of all these titles, that of the Earl of Selkirk belonging since 1885 to the Duke of Hamilton, and that of Earl of Belhaven, survive; the others are dormant or extinct.

See the *History of the Houses of Douglas and Angus*, by David Hume of Godscroft (1644, 1 vol. fol.; reprinted in 1748; extended from his *Origin and Descent of the Family of Douglas*, c. 1633); the *Douglas Book*, by Sir W. Fraser (from family muniments, 4 vols. 1885); and Sir H. Maxwell, *History of the House of Douglas* (2 vols. 1902).

Douglas, DAVID (1798–1834), botanist and traveller, born at Scone, became a gardener, collected in North America, discovered and introduced many plants, including the Douglas fir (*Tsuga*, or *Pseudotsuga Douglasii*), and was killed by a wild bull in a pitfall in Hawaii. See his *Journal* (1915).

Douglas, GAWAIN or GAVIN, the poet-bishop, the third son of Archibald 'Bell-the-Cat,' fifth Earl of Angus, was born at Tantallon Castle about 1474. He was educated at St Andrews for the priesthood, and in 1496 was first presented to Monymusk, Aberdeenshire, but ere long was appointed to Prestonkirk, near Dunbar, then called Hauch or Prestonhaugh. In 1501 he was made dean or provost of St Giles, Edinburgh, and while holding these preferments he wrote all his poems. From the marriage of his nephew, the sixth Earl of Angus, to the widowed queen of James IV., Douglas expected rapid preferment; but the jealousy of the nobility and the Regent Albany was such that he was disappointed of the abbacy

of Aberbrothock and the archbishopric of St Andrews, and when, through the influence of the queen, he had obtained the bishopric of Dunkeld directly from the pope (January 1515), he was imprisoned on an old statute for receiving bulls from the pope, and not allowed to be consecrated until more than a year after. On the fall of the party of Angus, after the queen, stung by his ill-treatment, had flung herself into the arms of Albany and determined on a divorce, the bishop fled to England to obtain the aid of Henry VIII., but was suddenly cut off at London by the plague in 1522, and buried in the hospital church of the Savoy. The extant poems attributed to Douglas are *The Palace of Honour*, most likely written in 1501, an allegory of the life of the virtuous man; a translation of the *Æneid*, with prologues; and *King Hart*, an allegory of the human heart in its struggle with the temptations of the flesh, of disputed authorship, not printed apparently till it appeared in Pinkerton's *Ancient Scottish Poems* (1786). There is also a short poem entitled *Conscience*, whose beauties are sadly marred by excessive conceits. Throughout his verse Douglas shows his deep indebtedness to Chaucer, but his youthful exuberance of ornament, his sense for colour and splendour, and the vigour of his 'braid and plane' Scots dialect, are his own. His *Æneid*, which he finished most likely about 1513, was the first version of a Latin classic published in English; it remains to Gawain Douglas no small achievement in the history of English literature, that 'in a barbarous age he gave rude Scotland Virgil's page.' His collected works were edited by Dr John Small (4 vols. Edin. 1874). See also histories of literature by J. M. Ross (1884), T. F. Henderson (1898), J. H. Millar (1903), and others, and G. Gregory Smith, *The Transition Period* (1900).

Douglas, SIR HOWARD, Bart., G.C.B., son of Admiral Sir C. Douglas, was born at Gosport in 1776, and served in Canada (1795) and in two Peninsular campaigns, being present at Corunna. He was successively governor of New Brunswick (1823-29), where he founded the university of Fredericton, of which he was the first chancellor, Lord High Commissioner of the Ionian Islands (1835-40), and M.P. for Liverpool (1842-46). He wrote several treatises accepted as authoritative at the time, among which are *An Essay on Military Bridges* (1816), which is said to have given Telford the idea of the suspension principle; a treatise on *Naval Gunnery* (1819; 5th ed. 1860, reproduced in America, France, and Spain); *Observations on Carnot's Fortification*; a work on the value of the British North American provinces (1831); and *Naval Evolutions* (1832). He died 9th November 1861. See Life by S. W. Fullon (1862).

Douglas, JOHN, Bishop of Salisbury, the son of a shopkeeper of Pittenweem, Fifeshire, was born 14th July 1721. He was educated at Dunbar and Oxford, ordained deacon in 1744, and as an army chaplain was at the battle of Fontenoy (1745). His after-life is little more than a chronicle of his very numerous preferments, which ended in his translation to the see of Salisbury in 1791. He died 18th May 1807. Douglas only occasionally resided on his livings. He generally spent the winter months in London, and the summer months at the fashionable watering places, in the society of the Earl of Bath, who was his great patron. He wrote much, mainly controversial: defending Milton from Lauder's charge of plagiarism (1750), writing on miracles (1754) against Hume, attacks on the Hutchinsonians, and political pamphlets. See his *Miscellaneous Works* (with Life, 1820).

Douglas, NORMAN, a distinguished prose-writer, scholarly, vivacious, wayward, and delicately brutal, has written baffling novels: *South Wind* (1917), *They Went* (1920); unconventional travel books: *Siren Land* (1911), *Fountains in the Sand* (1912), *Old Calabria* (1919), *Alone* (1921), *Together* (1923); giving reminiscences of boyhood in Tyrol; and *Experiments: A Miscellany* (1925).

Douglas, SIR ROBERT (1694-1770), a Scottish baronet, author of a *Peerage of Scotland* (1764); completed by Wood (2 vols. 1813). A new edition—substantially a new work on a larger scale and on a more critical method—was edited by Sir James Balfour Paul, Lyon King, in 1904-14.

Douglas, STEPHEN ARNOLD, born at Brandon, Vermont, in 1813, practised law in Illinois, and was successively attorney-general of this state, member of the legislature, secretary of state (1840), and judge of the supreme court (1841). He was returned to congress in 1843-44-46, and to the United States senate in 1847-52-58. In the lower house he advocated the annexation of Texas, and of Oregon up to 54° 40' N. lat., and favoured the war with Mexico, and in the senate he opposed the ratification of the Clayton-Bulwer Treaty, and declared himself in favour of the acquisition of Cuba, his desire being to 'make the United States an ocean-bound republic.' On the question of slavery he maintained that the people of each territory should decide whether it should be a free state or a slave state; this was known as the doctrine of 'popular' or 'squatter sovereignty.' In 1860 he received the regular Democratic nomination for the presidency, the seceding delegates nominating John C. Breckinridge. Douglas obtained 12 electoral and 1,375,157 popular votes, as against 180 electoral and 1,866,352 popular votes cast for Lincoln, to whom, in the early days of the rebellion, he gave an unfaltering support. He died 3d June 1861, at Chicago, where an imposing monument, surmounted by a statue, has been erected. See books by Sheehan (New York, 1860), Flint (Phila. 1860), Allen Johnson (1908), Willis (1910), and *Political Debates* (1913).

Douglas, SIR WILLIAM FETTES, P.R.S.A., was born at Edinburgh, 29th March 1822. He studied in the university there, and was for several years engaged in business. As a painter he was mainly self taught, though he attended the Trustees' Academy for a short time. At first he practised chiefly as a landscape painter, but he soon turned to figure-subjects, producing works distinguished by excellent colouring, and by especially firm, careful, and refined handling. His later years were entirely devoted to landscape water-colours. He was elected A.R.S.A. in 1851, R.S.A. in 1854, and P.R.S.A. in 1882. He died 20th July 1891.

Douglass, FREDERICK, an American orator, was born at Tuckahoe, near Easton, Maryland, in 1817, his father being a white man, his mother a negro slave. Permitted to work in a shipyard in Baltimore, he in 1838 escaped to New York, and thence to New Bedford, Massachusetts, where his negro employer, who had just read Scott's *Lady of the Lake*, induced him to substitute Douglass for the name of Bailey, conferred on him by his mother. In 1841 he attended an Anti-slavery Convention at Nantucket, and spoke so eloquently on the subject of slavery that he was employed as agent of the Massachusetts Anti-slavery Society, and lectured for four years with great success. In 1845 he commenced a lecturing tour in Great Britain, where a contribution of £150 was made to 'buy his freedom.' Returning to America, he established in 1847 *Frederick Douglass's Paper*, a weekly abolition newspaper at Rochester, New York. Successively

assistant-secretary to the Santo Domingo Commission (1871), marshal and recorder for D.C., and minister to Hayti (1889-90), he died in 1895. See his autobiography (1882), and *Lives by Holland* (1891), Chesnutt (1899), and *Booker Washington* (1907).

Doukhobors. See DUKHOBORTZI.

Doulton, Sir Henry, the head of the famous firm of Lambeth potters, was born at Lambeth, 24th July 1820, and on attaining his fifteenth year entered his father's establishment there. He devoted himself to the most technical branch of the industry, and worked for many years at the potter's wheel. In 1846 he began the manufacture of stoneware pipes for sewage and drainage, for which a special factory was erected near Lambeth Palace, and thus initiated the substitution of impervious pipes for the old flat-bottomed brick drains, with their gaping joints; in 1848 drain-pipe works, which became the largest in the world, were started at Rowley Regis, near Dudley. Sir Henry Doulton, however, is chiefly noteworthy as having been mainly instrumental in bringing about the revival in art pottery which has since spread into every civilised country; and his firm's works in art stoneware, silicon, impasto, terra-cotta, faience, and Doulton wares, have since 1870 excited the admiration of critics. Created a Chevalier of the Legion of Honour (1878), and knighted (1887), he died 17th November 1897. See POTTERY.

Doumic, René, French man of letters, critic, and journalist, born in Paris in 1860, was educated at the Ecole Normale, and taught rhetoric at the Collège Stanislas. A contributor to the *Moniteur*, the *Journal des Débats*, and the *Revue Bleue*, he is most notable as a member of the staff of the *Revue des Deux Mondes*, of which he became editor. He is author of a number of works in literary history, biography, and criticism. He was admitted to the Academy in 1909.

Doum Palm. See DUM PALM.

Donne, a village of Perthshire, on the Teith, 9 miles NW. of Stirling by rail. Pop. 900. Donne Castle, built by Mardoch, Duke of Albany, in the early part of the 15th century, is now a magnificent and well-preserved ruin. It is described in *Scott's Waverley*, and was reduced to ruins by Hawley's dragoons in 1746. A mile to the west is Deanston, with its cotton-mills, long managed by James Smith (1789-1850), notable as an inventor, as the promoter of 'deep draining and thorough ploughing,' and as a philanthropist.

Douro (Span. *Duero*), one of the largest rivers of Spain and Portugal, rises in the Pico de Urbión (7369 feet), in Old Castile, about 30 miles NW. of Soria (3445 feet above sea-level). From its source it flows south-east to Soria, then winds towards the west, and pursues a general westward direction till it reaches the Portuguese border, when it flows south-west for about 60 miles, forming the boundary between Spain and Portugal, and then flows west through Portugal, entering the Atlantic below Oporto. Its Portuguese tributaries are comparatively small. Of its 490 miles, 90 are navigable.

Douw. See Dow.

Dove, a river rising 4 miles SW. of Buxton, and flowing south and south-east along the borders of Derbyshire and Staffordshire to the Trent, which it enters at Newton Solney, after a course of 45 miles. It was the favourite fishing stream of Izaak Walton, who lived here with his friend, Charles Cotton; and it is still beloved of anglers. —DOVEDALE is a romantic glen, forming the course of the 'princess of rivers' for 3 miles, between Thorpe Mill and Mill Dale, below Alstonfield. It is hemmed in by fantastic walls of limestone rock,

and presents a series of fairy-like combinations of rock and wood and water.

Dove. See PIGEON, TURTLE-DOVE.

Dove. In Christian art, as early as the 6th century, the dove was employed as an emblem of the Holy Ghost, of course from the words of Luke, iii. 22, which do not, however, state that the Spirit descended on our Lord at his baptism in the bodily form of a dove, but simply 'in a bodily form, as a dove'—i.e. with the fluttering motion of a dove. From the dove being also used to symbolise purity, it is generally represented white, with its beak and claws red, as they occur in nature. In the older pictures, a golden nimbus surrounds its head; the nimbus being frequently divided by a cross, either red or black. In stained glass windows we see the dove with seven rays proceeding from it, terminating in seven stars, significative of the seven gifts of the Holy Spirit. Holding an olive branch, the dove is an emblem of peace. When seen issuing from the lips of dying saints and martyrs, it represents the human soul purified by suffering. A dove with six wings is a type of the Church of Christ; and when so employed it has the breast and belly of silver, and the back of gold, two wings being attached to the head, two to the shoulders, and two to the feet. The pyx containing the host was sometimes made in the form of a dove, and suspended over the altar; and the dove is often placed on the covers of fonts. In this position it may still be seen in some parish churches in England.

Döve, Heinrich Wilhelm, physicist and meteorologist, was born in 1803, at Liegnitz, in Silesia, studied at Breslau and Berlin, and in 1845 became professor of Natural Philosophy at Berlin, where he died, 4th April 1879. He laboured successfully in many fields of science, especially optics and electricity; but his greatest services were rendered to meteorology, which he did much to establish on a scientific basis. He was from 1848 director of the Royal Meteorological Institute, with over eighty stations. To him is due, amongst a great variety of optical discoveries, the application of the stereoscope to the detection of forged bank-notes. Dove was a voluminous writer; his treatise on the *Distribution of Heat on the Surface of the Globe* was published in 1833 by the British Association, and his notable *Das Gesetz der Stürme* (4th ed. 1874) has also been translated.

Dovecot. The right of erecting and keeping dovecots was in England formerly a privilege of manors, and was rigorously protected by law; but such exceptional privileges have long been abolished. It is enacted by the Scottish statute 1617, chap. 19, still in observance, that no person shall build a dovecot or pigeon-house, either in town or country, unless he be possessed of lands or teinds of the yearly value of ten chalders of victual, lying within at least two miles of it. No person having such qualification shall build more than one dovecot within the 'bounds foresaid.' Dovecot breakers are guilty of theft; and under a rigorous Act of 1879, a third offence of dovecot breaking was capitally punishable. See Rankine *On Landownership*, p. 146 (4th ed. 1909).

Dovekie. See ROTCHE.

Dover, a Cinque Port and municipal (till 1918 parliamentary) borough in the east of Kent, 66 miles ESE. of London, is not only a charmingly situated watering-place, but, being the nearest point of the English coast to France, is a seaport of growing importance, with mail service to Calais and Ostend. In 1891 parliament sanctioned great harbour works—the Admiralty pier (dating partly from 1844) being extended, and a new east pier built so as to enclose a commercial harbour of 36 acres. To the east of this a National Harbour of

610 acres was made in 1897-1909. The fortifications comprise Dover Castle, which occupies a commanding position on the chalk cliffs, 375 feet above the level of the sea, and still includes some of the old Saxon and Norman work; Fort Buigoine on the north side of the town, Arcliffe Fort to the west, and the batteries on the Western Heights. There are also the remains of a Roman pharos or lighthouse, and of a Romano-British church (restored). Dover has a town-hall, a museum, a hospital, great barracks, and a large number of churches. The Duke of York's Royal Military School was removed from London to Dover in 1907. The town is chiefly dependent on its shipping trade and its attractions as a watering-place, but shipbuilding and sail and rope making are carried on, and there are also flour and paper mills. Coal is mined near Shakespeare Cliff. Formerly it returned two members to parliament, in 1885-1918 but one. Pop. (1881) 28,486; (1921) 39,985. Dover is well sheltered by the cliffs, and ends landward in a charming valley leading to what is known as 'The Garden of Kent.' By the Romans it was known as *Portus Duri*; the Normans called it *Dovere*; the French, *Douvres*; whilst in legal documents of this day the town is *Dovar*, all four terms being variations of the Celtic word 'Doni,' the name of the small river which runs through the town. Fortified and walled by William the Conqueror, during whose reign it was nearly burned down, noted as the place of King John's submission to the pope, besieged by the French, held during the Civil War by the parliamentarians, threatened by the first Napoleon, and celebrated as the headquarters of the Lord Wardens of the Cinque Ports (see CINQUE PORTS), and the base for the defence of the Straits in the Great War, Dover holds a distinguished place in English history. Submarine cables connect it with the Continent, and here is the entrance to the proposed Channel Tunnel (q.v.).

Dover. (1) the capital of Delaware, U.S.A., on Jones's Creek, 48 miles S. of Wilmington. It has a state-house, and several canning and other factories. Pop. 4000.—(2) The oldest city of New Hampshire, founded in 1623, is situated on the Cochecho River, 68 miles N. by E. of Boston by rail, and has large cotton-mills, besides manufactures of boots and shoes, woollens, and iron. Pop. 13,000.

Dover, ROBERT (1575-1641), a Warwickshire attorney, founded and for near forty years directed the 'Colswold games' (see ATHLETIC SPORTS).

Dover, STRAIT OF (Fr. *Pas de Calais*), the channel between England and France, connecting the English Channel and the North Sea, whose tides meet here. It is 18 to 25 miles broad, and 6 to 29 fathoms deep. On 24th August 1875, Captain Webb swam from Dover to Calais in 21½ hours. Blériot, on 25th July 1909, was the first to fly across. See CHANNEL (ENGLISH).

Dovercourt. See HARWICH.

Doveron. See DEVERON.

Dover's Powder was first prescribed by Thomas Dover, M.D. (1660-1742), who in 1709, whilst captain of a privateer, took Alexander Selkirk off from Juan Fernández. The powder was prepared by mixing powdered ipecacuanha root, 1 part; powdered opium, 1 part; and sulphate of polash, 8 parts. The whole was thoroughly mixed, and the ordinary dose was from 5 to 10 grains. Occasionally, saltpetre was added. It is a most valuable medicine, and acts as a sudorific, increasing the proportion of sweat. In feverish conditions, where there is dry furred tongue, and dry skin, and the brain out of order, Dover's powder is reckoned injurious; but where the tongue is moist and soft, the skin moist and soft, and the brain compara-

tively unaffected, it is of great service. In heartburn 3 to 4 grains will often give relief.

Dovrefeld, part of the mountainous plateau of Norway, connecting the Kiølen Mountains with the Jotun Fjelde, lies between 63° and 62° 40' N. lat. The average elevation ranges from 2650 to 3600 feet; the highest point is Snebbatten, 7566 feet. The main railway from Christiania to Trondhjem by Gudbrandsdal (opened 1921) crosses the Dovrefjeld (at Hjerkin) by a pass 3334 feet above sea-level.

Dow, or **DOU,** GERARD, Dutch *genre*-painter, was born at Leyden on 7th April 1613. He studied under Bartolomeus Dolendo, an engraver, and Pieter Kouwenhoven, a glass-painter, and at the age of fifteen entered the school of Rembrandt. The influence of the last-named master is very visible in his Arundell picture of a scene from the life of Tobit. At first he mainly occupied himself with portraiture, but he soon turned to *genre*, treating, with extreme care, familiar subjects, small in scale, with few figures, and with little dramatic action. The most insignificant incidents of daily life were precious to Dow, and were delineated with the utmost delicacy, neatness, and care. The richness, transparency, vigour, and harmony of his colouring are beyond all praise, but his touch is minute, his way of work a little trivial, and wanting in the largeness and breadth which distinguish the productions of the greater *genre*-painters of Holland. His works, of which about 200 have been catalogued, are in all the great European collections. His own portrait, that of his wife, and 'The Poulterer's Shop,' are in the National Gallery, London; his celebrated 'Tropical Woman' (1663) is in the Louvre, along with ten other examples of his art; the Amsterdam Museum contains five of his works, and the Dresden Gallery no fewer than sixteen. Dow died at Leyden in 1675. See a book by Martin (trans. 1908).

Dowager (Old Fr. *douagere*, from *douage*, 'dowry'), a widow with a dower; but commonly the title is applied only to the widows of persons of high rank. For queen-dowager, see QUEEN.

Dowden, EDWARD (1843-1913), was born in Cork, and was educated at Trinity College, Dublin, where his course was remarkably distinguished. In 1867 he became professor of Oratory and of English Literature at Dublin University. Dowden contributed many able articles to the leading magazines, and proved himself a profound Shakespearean, and a critic of uncommon insight and capacity, by his *Shakspeare: A Study of his Mind and Art* (1875), the invaluable *Shakespeare primer* (1877), *Studies in Literature: 1789-1877* (1878), *Southey* (1879), and *Transcripts and Studies* (1888). In 1876 he published poems, in 1881 an edition of Shakespeare's *Sonnets* and *The Correspondence of Southey and Caroline Bowles*, in 1886 his authoritative *Life of Shelley*, and in 1904 his *Browning*; besides several volumes of *Studies*, *A History of French Literature*, and editions of Shelley, Wordsworth, Southey, &c. He contributed important articles to *Chambers's Encyclopædia*. *A Woman's Reliquary* (poems, 1913) and *Fragments from Old Letters* (1914) were posthumous.

Dower. See HUSBAND AND WIFE, JOINTURE.

Dowie, JOHN ALEXANDER (1847-1907), born at Edinburgh, was a Congregational minister in Sydney, but becoming a faith healer and calling himself 'Elijah the Restorer,' founded in Illinois a prosperous industrial and banking community called 'Zion City.' Charged with advocating polygamy, he was in 1906 deposed from the leadership of the Zionist Church.

Dowlais. See MERTHYR-TYDVIL.

Dowland, JOHN (c. 1563–c. 1626), composer, was lutanist at the Danish (1598) and English (1612) courts, travelled much, and wrote songs and lute music. See his three *Books of Aires* (ed. E. W. Fellowes, 1921 *et seq.*).

Dowlas, a coarse, strong, unbleached linen, used for joiners' aprons, and in some districts for sheets and pillow-cases, and even for workpeople's shirts; but it is falling out of use.

Dowlatabad. See DAULATABAD.

Down, the Kentish home of Darwin (q.v.).

Down, a maritime county of Ireland, in the south-east of the province of Ulster, 50 miles long (N.E. to S.W.) and 35 broad (N.W. and S.E.). Area, 609,239 acres; pop. (1841) 368,143; (1881) 272,107; (1911) 304,589. It has a coast-line of 67 miles, or 139, counting inlets and islets. It has four spacious inlets: Belfast Lough, Strangford Lough, Dundrum and Carlingford Bays. The Mourne Mountains cover 90 sq. m. in the south, and rise in Slieve Donard to 2796 feet. The other parts of County Down are mostly undulating and hilly, with plains and fine meadows along the rivers. The chief rivers are the Upper Bann and the Lagan. The Newry Canal admits vessels of 50 tons, and with the Ulster Canal opens communication through almost all Ulster. Nearly one-half of the entire area is under crop, mostly oats, potatoes, turnips, wheat, flax, and barley. Many pigs, horses, and cattle are reared for export. The chief manufacture is linen, especially the finer fabrics, as muslin, woven in the houses of the small farmers, but hosiery, leather, salt, thread, and woollens are also made; and these, with corn, butter, pork, and hides, are the chief exports. Down is among the best cultivated of the Irish counties, and has more resident gentry (almost all Protestants, of English and Scottish descent) than any other Ulster county. Of its population, some 39 per cent. are Presbyterians, and about 31 per cent. Roman Catholics, while about 22 per cent. are Episcopalians. It sends two members to Westminster and eight to Belfast. Newry was a parliamentary borough till 1918. The chief towns are Downpatrick, Newry, Newtownards, Banbridge, Lisburn, Holywood, Donaghadee (with part of Belfast till 1898). County Down contains many ancient remains, as raths, round towers, castles, and abbeys. On the top of Slieve Croob (1755 feet) are twenty-three stone cairns, one being 54 feet high. See Alex. Knox, *History of County Down* (Dublin, 1875).

Downham Market, an urban district of Norfolk, on the right bank of the Ouse, in a flat fen country, 10 miles S. by W. of Lynn; pop. 3500.

Downing Street, a short street in Whitehall (named after Sir George Downing, secretary to the Treasury in 1667), where are the Colonial and Foreign Offices, with the official residence since 1735 of the First Lord of the Treasury. Here cabinet councils are held, hence the term is sometimes employed for the government in office.

Downpatrick, or simply **DOWN**, the capital of County Down, situated near the influx of the Quoyle into the south-west end of Lough Strangford, 27 miles S.E. of Belfast, and 140 N.N.E. of Dublin by rail. Downpatrick takes its name from St. Patrick, and is the seat of the diocese of Down, which was united with that of Dromore in 1842. It returned a member to parliament till 1885. Vessels of 100 tons reach the quay a mile from Downpatrick. Its chief manufacture is sewed muslin. Pop. 3200.

Downs (from the root *dun*, 'a hill,' borrowed by Teutonic languages from Celtic, seen also in *Fr. dune*), a term applied, like *denes* in Norfolk, to hillocks of sand thrown up by the sea or the wind along the sea-coast (see **DUNES**, **DRIFT**). It is also

a general name for any undulating tract of upland too light for cultivation, and covered with short grass. It is specially applied to two broad ridges of undulating hills south of the Thames, beginning in the middle of Hampshire, and running eastward, the one (the North Downs) through the middle of Surrey and Kent to Dover (about 120 miles), and the other (the South Downs) through the south-east of Hampshire and near the Sussex coast to Beachy Head (about 80 miles). Between the two ranges lies the valley of the Weald, from which the chalk strata have been removed by denudation. Towards the Weald, the descent from both Downs is rapid, and presents cliffs as of a scarp-margin; while the opposite slopes are gradual. The highest point of the North Downs is Inkpen Hill (1011 feet); and of the South Downs, Butser Hill (889 feet). These uplands are covered with fine short pasture, which, from its aromatic quality, forms excellent feeding-ground for the famous Southdown sheep.

Downs, **THE**, a roadstead for shipping off the east coast of Kent, opposite Ramsgate and Deal, between North and South Foreland, and protected externally by the Goodwin Sands—a natural breakwater with 1 to 4 fathoms water, and often partly dry at low tide. This large natural harbour of refuge is 8 miles by 6, with an anchorage of 4 to 12 fathoms. It is unsafe only in south winds. The Small Downs, an appendage of the Downs proper, lies inside the Blake Sand, has from 2½ to 3 fathoms water, and is about 2 miles wide. The obstinate but indecisive battle of the Downs was fought in June 1666, between the English under Monk, and the Dutch under De Ruyter, De Witt, and Van Tromp. See also **BLAKE** (**ROBERT**).

Downton, a town of Wiltshire, on the right bank of the Avon, here split into three branches, 6 miles S.S.E. of Salisbury. It has an Early English market-cross, a cruciform church, and a singular earthwork (the Moot); whilst 2 miles north is Trafalgar House, presented in 1814 by the nation to Lord Nelson's brother and successor. For the agricultural college (1890), see **AGRICULTURE**.

Dowsing. See **DIVINING ROD**.

Dowson, **ERNEST** (1867–1900), poet, studied at Oxford, lived much in France, frequented low haunts, drank, and died before his time. He wrote a couple of novels and some short stories, but will live by his delicately finished poems (collected, with memoir by Arthur Symonds, 1900).

Doxology (Gr., 'a praising'), an exclamation or prayer in honour of the majesty of God, such as Paul uses at the close of his epistles, and sometimes even in the middle of an argument (Rom. ix. 5). The hymn of the angels (Luke, ii. 14) is also called a doxology by the Christian church; so likewise are the close of the 'Lord's Prayer' and the 'Trisagion' ('Holy, holy, holy'). The so-called 'Greater Doxology,' which is simply an expansion of the angelic hymn, in the Roman liturgy is placed immediately after the beginning of the Mass, and in the English Prayer-book at the close of the communion office. It commences with the words, *Gloria in excelsis Deo* ('Glory to God in the highest'). The Lesser Doxology, 'Glory be to the Father, and to the Son, and to the Holy Ghost, as it was,' &c., is repeated at the end of each psalm in the service of the Roman and Anglican churches. The Greater Doxology is of Eastern origin, and is first met with, though not in its final form, in the seventh book of the Apostolic Constitutions (q.v.), where it is described as the 'morning prayer'; but it is probable that this, as well as the Lesser Doxology and the 'Trisagion,' came into use at a much earlier date, as the Scriptures began to circulate among the churches, the 'Trisagion' (cf.

Isa. vi. 3) being presumably the earliest. The origin of the Lesser Doxology (perhaps traceable to Matt. xxviii. 19) is the most obscure, and it is only certain that its present form is the result of the Arian controversy, the second clause having been unknown in Christendom for several centuries.

Doyle, Sir Francis Hastings, poet, was born at Nunapleton, near Tadcaster, August 22, 1810. He was educated at Eton, and Christ Church, Oxford, and took a first-class in classics in 1831. He was called to the bar, but his devotion to poetry and his innate love of horses and horse-racing were hardly consistent with success as a barrister. He succeeded his father as second baronet in 1839, held lucrative offices in the Customs, and filled for ten years (1867-77) the chair of Poetry at Oxford, together with an All Souls' fellowship. In 1886 he published his *Reminiscences and Opinions, 1813-1886*, which revealed its author's genial humour, broad sympathies, and liberal culture. Doyle died June 8, 1888. His two series of Oxford lectures he published in 1869 and in 1877; his volumes of verse were *Miscellaneous Verses* (1841), *Two Destinies* (1844), and the *Return of the Guards, and other Poems* (1866). By his 'Birkenhead,' 'The Private of the Buffs,' 'The Red Thread of Honour,' 'The Saving of the Colours,' and 'Gordon,' he made himself in an especial sense the laureate of English heroism.

Doyle, Richard, caricaturist, was born in London in 1824, second son of John Doyle (1797-1868), who was himself a celebrated caricaturist, under the signature H. B. He received instruction in art from his father, and became a contributor to *Punch*, the current design on the cover being from his pencil, and furnished its pages with the well-known sketches of 'Ye Manners and Customs of ye Englyshe.' In 1850 his connection with *Punch* ceased, owing to its criticisms of the Roman Catholic Church, of which he was a member, and he afterwards employed himself in the illustration of books. Among his works of this nature may be mentioned the *Adventures of Brown, Jones, and Robinson*, and the illustrations to the *Newcomes*, the *Scouring of the White Horse*, to Leigh Hunt's *Jar of Honey*, and Ruskin's *King of the Golden River*. He contributed 'Sketches of Modern Society' to the *Cornhill Magazine*, and published a Christmas book for 1869, called *In Fairy Land*. Doyle drew with care, accuracy, and skill thousands of animated little figures, and his caricatures are all distinguished by the most genial humour, and the most graceful drawing. He was also a clever painter in water-colours, and his work in this medium was frequently exhibited at the Grosvenor Gallery. He died December 11, 1883.

His nephew, **Sir A. Conan Doyle**, was born at Edinburgh in 1859, and educated at Stonyhurst and in Germany. He studied medicine at Edinburgh in 1876-80, and practised as a doctor at Southsea in 1882-90, subsequently devoting himself wholly to literature. His *début* was an article in *Chambers's Journal* in 1879; and *The Captain of the Polestar* (1887), *A Study in Scarlet* (1888), *The Mystery of Cloombur* (1888), *Micah Clarke* (1889), and *The White Company* (1891) were early stories. But it was by the preternatural acumen of the hero of his detective stories, *The Adventures of Sherlock Holmes* and *The Memoirs of Sherlock Holmes* (originally in the *Strand Magazine*; as books, 1892 and 1893), that Conan Doyle became known to a very wide circle of readers. Later works are *The Refugees*, *The Red Lamp*, *The Stark-Munro Letters* (1895), and *Rodney Stone* (1896); a play, *A Story of Waterloo*; *The Great Boer War* (1900), incorporating his experiences as a surgeon in the field; books on the Great War and

on spiritualism. He contested Central Edinburgh (1900) and Hawick burghs (1905) as a Unionist.

Dozy, Reinhart, a learned Orientalist, was born 21st February 1820, at Leyden, and studied there. In 1844 he obtained a post in the library, and in 1850 he was appointed extraordinary, and in 1857 ordinary, professor of History at Leyden. He died 29th April 1883. His *Histoire des Musulmans d'Espagne* (1861; Eng. trans. 1913) is a model of what a history should be. His earlier *Recherches on Spain in the middle ages* (1849; 3d ed. 1881) exposed the wilful corruptions of the monkish chroniclers, and destroyed many popular illusions based upon the Poem and Chronicle of the Cid. Other publications are the *Historia Abbadidarum* (1852), and editions of Al-Marrakushi, Ibn-Badrūn, Ibn-Adhari, Al-Makkari, and with De Goeje, of Edrisi (q.v.); a supplement to Arab dictionaries (2 vols. 1877-81); *Het Islamisme* (1893; French trans. 1879); *De Israëlieten te Mekka* (1864); and a work (1884) on the religion of the Harranians.

Dracæna. See DRAGON-TREE.

Drachenfels ('Dragon's Rock'), a peak of the range called the Siebengebirge, on the right bank of the Rhine, 8 miles S.E. of Bonn, and has an elevation of 1056 feet. Its top, which commands a glorious prospect, may be gained by a mountain railway (1883).

Drachma, Drachm, Dram. The drachma was a silver coin, the unit of the money-system in ancient Greece. It varied in value in different parts of Greece and at different times, but always remained the 6000th part of the talent, and the 100th part of the mina, and was divided into six obols. The Attic drachma is estimated as equivalent to 92d. of our money—very nearly a French franc. The drachma (originally 'a handful') was also the name of a weight, and 100 drachmas made a mina (nearly 1 lb.) in weight, as in money. The unit in the monetary system of modern Greece, since 1833, is also called a drachma, which is divided into 100 lepta. In 1868 Greece entered the Latin Monetary Union, and the drachma became equal to the franc. The modern Greek weight called drachma was equal to $\frac{1}{4}$ oz. avoirdupois. In the British system of weights there were, till recently, two drachms or drams: the avoirdupois, equal to $\frac{1}{16}$ oz., and the apothecaries' (not now used), equal to $\frac{1}{8}$ oz. See DIRHEM.

Drachmann, Holger Henrik Herbolt (1846-1908), Danish poet, dramatist, and novelist, was born at Copenhagen, son of a physician of German family. He studied art, became a marine painter of some merit, travelled much, and acquired a knowledge of the lives of seamen. For a time a radical of the school of Biances, he became afterwards a nationalist conservative.

Draco (Gr. *Drakōn*), an Athenian lawgiver and archon, who, in the year 621 B.C., was appointed to draw up new laws for the disordered state. These, however, effected little change in the form of the state; but by being committed to writing, put an end to the arbitrary administration of justice on the part of the archons, and resulted in the establishment of a court of appeal—that of the Epheta. Draco's legislation had a beneficial and permanent effect upon the political development of Athens. The extraordinary severity of these laws, however, which punished the slightest theft, or even laziness, with death, no less than sacrilege, murder, and treason, caused them to be often neglected, and made them so hated, that Solon was appointed to draw out a new code of laws (594). These were termed *nomoi*, as opposed to the *thesmoi* of Draco. Solon, though he softened their severity in most instances, retained that law which punished a murderer with death. Draco at a later

period went to Ægina, where, after having introduced his laws, he is said to have been stifled in the theatre by the garments thrown upon him as a mark of respect by the people. The severity of his laws gave rise to a pun by Herodicus, who declared that Draco's laws were those of a dragon (Gr. *drakōn*) and not of a man. Hence also originated the metaphorical remark of Demades, 'that they were written not in ink but in blood.' Extremely severe and sanguinary laws are still called *Draconic*.

Draco, a constellation in the northern hemisphere. The star γ Draconis, a bright star nearly in the solstitial colure, was used in determining the coefficient of aberration of the fixed stars.

Dracontium, a genus of Araceæ, of which one West Indian species, *D. polyphyllum*, has a medicinal history and repute similar to that of Green Dragon (see DRAGON, GREEN). The poisonous tubers yield starch on washing.

Dracontius, BLOSSIUS ÆMILIUS, Latin Christian poet of the 5th century, an advocate at Carthage, was imprisoned by a king of the Vandals. His *De Laudibus Dei* tells the story of Creation. He probably wrote a tragedy, *Orestes*.

Draft, a written order for the payment of money. It is properly distinguished from a bill by being addressed by the drawer, not to his debtor, but to his agent, servant, or correspondent. This distinction is, however, little attended to.

Drag, a mechanism for slackening the speed of carriages, by operating on one or more of the wheels. The form of drag best known to old travellers by coach was that of the 'shoe,' a hollow piece of iron attached by a chain to the carriage, which being put below one of the hind wheels partially reduced the vehicle to the nature of a sledge. As the shoe-drag required to be applied and removed with some inconvenient detention of the vehicle, a step was made in advance when a method of retarding a wheel without detention was discovered. The mechanism is operated by the driver without moving from his seat. A handle affects a series of rods and levers by which a block is pressed against each of the two hind wheels, so as to slacken their motion. It is of French origin. In the case of vehicles used for heavy loads, the levers are worked by a handwheel and screw instead of a handle. See BRAKES.

Dragoman (from Arab. *tarjūmān*, 'interpreter'; cf. TARGUM), the general name given in Eastern countries to an interpreter, or to a guide to foreigners. The dragoman is, however, much more than the Italian *cicerone*, or the French *commissaire* or *violet de place*. In Syria, for example, he is a contractor for the management of expeditions, and undertakes to solve all the difficulties that arise between the traveller and the natives. The dragomans attached to embassies have special privileges. 'Student-dragomans' is a term sometimes given to 'student-interpreters' preparing for the consular service in the East. See CONSUL.

Dragon, (1) a name surviving from mythology and imaginative beast-lore, as the scientific title of a genus of arboreal lizards, of which the most familiar is *Draco volans*. The genus is especially remarkable for the extension of the skin of the sides on the prolonged posterior ribs. A parachute is thus formed which enables these 'dragons' to take rapid swoops from branch to branch. The tail is very long; the skin of the throat forms a loose wattle; the colours are particularly brilliant. There are several species inhabitants of the East Indies, not including Ceylon.—(2) The term dragon has also been applied in modern times to a large lizard (*Therictis dracena*) found in Brazil and

Guiana. It attains a length of 3 feet, most of which goes to the tail. Tejus and Ameiva are allied genera.—(3) The ancient myths might to

Fringed Dragon (*Draco fimbriatus*).

some extent be rehabilitated in the application of the term 'dragon' to some of the extinct saurians. See LIZARD, REPTILE.

Dragon, in Mythology. In the mythical history and legendary poetry of most nations, the dragon holds a prominent place as the embodiment of the antagonistic and hostile principle as it has opposed itself to man from the earliest period in the world's history. In other words, the dragon is the emblem of all that is obstructive, loathsome, and horrible in nature, the ideal of the spirit of evil which is in opposition to the order, harmony, and progress of the human race. On the other hand, in both China and Japan, the 'Bob-tailed dragon' is an exception, where he is regarded with veneration. 'His fidelity as a friend,' says Mr Conway in his *Demonology and Devil Lore* (i. 105), 'led to the ill return of an attack by which his tail was amputated, and ever since his soured temper has shown itself in raising storms. When a violent tempest arises, the Cantonese say "the bob-tailed dragon is passing," in the same proverbial way as the Aryan peasants attribute the same phenomenon to their storm gods.' But this favourable aspect of the dragon is the exception. Again, whilst the serpent seeks the attainment of its object by cunning and deceitful artifices—crawling on its belly, and always assuming ostensibly characteristics the very opposite of its own—the dragon proceeds openly to work, running on its feet, with expanded wings, and head and tail erect, violently and ruthlessly making onslaught on its victim, spouting fire and fury from both mouth and tail, and wasting and devastating the whole land. Hence, as the universally recognised enemy of mankind, the overthrow of the dragon was made to figure as one of the greatest exploits of gods and heroes. As the highest ideal of human strength and courage, the task properly fell to Herakles; but it was not confined to him, for we find both Apollo and Perseus represented as dragon-slayers. In the Vedic mythology the dragon Vritra, the god of evil and darkness, is in antagonism to Indra, the god of light and good. From legendary poetry the dragon passed into art, and was depicted on the shield or carved for the crest of a conqueror's helmet. The dragon does not seem to have been a native emblem with the Romans, and when they ultimately adopted it as a sort of subordinate symbol, the eagle still holding the first place, it seems to have been in consequence

of their intercourse with Pelagic or with Teutonic nations. Amongst all the new peoples that overran Europe at the termination of the classical period, the dragon seems to have occupied nearly the same place that it held in the earlier stages of Greek life; in modern Greek folk-tales, the dragon is specially prominent. For the story of Cadmus and the dragon's teeth, see CADMUS. In the *Nibelungen Lied*, we find Siegfried killing a dragon at Worms; and the dragon killed by Beowulf (q.v.) in the epic that bears his name, is, as often in such stories, the enaged guardian of a tiled hoard of gold. Even Thor himself was a slayer of dragons (Grimm, *Deutsche Mythologie*, ii. 653). Among the Teutonic tribes which settled in England, it was from the first depicted on their shields and banners, and most of the dragon myths of Great Britain were no doubt importations brought over by early colonists—the celebrated Lambton worm being a survival of an ancient superstition. The Old English *wyrm*, meant equally dragon, serpent, and worm; and in such names as Ormsby, Ormskirk, we have reminiscences of the 'laidly [loathly] worm' of the old ballads. As a device, the dragon appears to have been the standard of the West Saxons, and of the English previous to the Norman Conquest. It formed one of the supporters of the royal arms borne by all Tudor monarchs, with the exception of Queen Mary, who substituted an eagle. Several of the Plantagenet kings and princes inscribed the figure of a dragon on their banner and shields. Peter Langtoffe says, at the battle of Lewes, fought in 1264, 'the king schewed forth his schild, his dragon full austere.' Amongst the Celts, it was the emblem of sovereignty, and as such borne as the sovereign's crest. Lord Tennyson's *Idylls* have made every one familiar with 'the dragon of the Great Pendragonship,' blazing on Arthur's helmet, as he rode forth to his last battle, and 'making all the night a stream of fire.'

The fiery dragon, or fire-drake, and the flying dragon in the air, were meteoric phenomena, of which we have frequent accounts in old books, and, indeed, as Brand remarks, 'the dragon is one of those shapes which fear has created to itself,' and which appears in circumstances, and clothes itself in forms, as various as our fears.

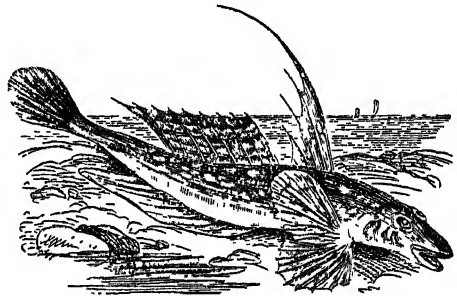

Of the two Hebrew words translated dragon in the authorised version of the Old Testament, one obviously means a serpent; while the dragon in Bel and the Dragon is a monster. The dragon of the Apocalypse is identified with the old serpent, the devil. In Christian art, the dragon is the emblem of sin, the usual form that is given to it being that of a winged crocodile. It is often represented as crushed under the feet of saints and martyrs, and other holy personages. Sometimes its prostrate attitude signifies the triumph of Christianity over paganism, as in pictures of St George (see GEORGE, ST), St Michael, and St Sylvester; or over heresy and schism, as when it was adopted as the emblem of the Knights of the order of the Dragon in Hungary, which was instituted for the purpose of contending against the adherents of John Huss and Jerome of Prague.

The dragon is often employed in heraldry, and figures of the heraldic dragon vary considerably according to the fancy of the draughtsman. The chief characteristics are the head of a wolf, the body of a serpent, four eagles' feet, bat-like wings, and barbed tongue and tail. An animal so represented is said to be *dragonné*. See GRIFFIN. A dragon without wings is called a lindworm, or lint-worm, which Grimm (*Deutsche Mythol.* ii. 652) explains to mean a beautiful or shining worm. It should be noted that in some of the older treatises on natural history full descriptions of the dragon

occur, the belief in its actual existence having been a widespread belief. Two of the ablest scientific writers of the 16th century, Conrad Gessner, professor of Natural History at Zurich, and Aldrovandi, the Pisan professor, have given elaborate descriptions of the dragon. In ancient mythology the task of drawing the chariot of the night was assigned to dragons, on account of their supposed watchfulness; and the loathsome ingredients for the witches' mess in *Macbeth* (IV. i) include 'the scale of dragon.' See Elliot Smith, *The Evolution of the Dragon* (1919).

Dragon, GREEN (*Arum (Dracunculus) vulgare*), an Araceous plant, with spotted petioles and handsome lobed leaves, and dark-coloured fetid flowers, is common in Greece and other countries of southern Europe, and is occasionally to be seen in gardens. The root-stock is acid, emetic, and was formerly of medicinal repute in the treatment of piles; also (apparently for no better reason than the doctrine of signatures could draw from the spotted stems) in the treatment of snake-bites.

Dragonet (*Callionymus*), a genus of spiny-rayed bony fishes near the Gobies (q.v.), remarkable for having the gill-openings reduced to a small hole on each side of the nape, and the ventral fins placed under the throat, separate, and larger than the pectorals. The species are numerous, widely distributed in the temperate seas of the Old World, and generally finely coloured. The Gemmeous Dragonet (*C. lyra*) of the British coasts—called *Gowdie* (*gowd*, 'gold') in Scotland—is a fish about 10 or 12 inches long, of a prevailing yellow colour

Gemmeous Dragonet (*Callionymus lyra*).

varied with spots of brown. At the reproductive season the male becomes very gorgeously adorned with blue and violet spots and stripes. This fish is also called Skulpin or Sculpin—a name given in America to a marine bull-head or *Cottus*.

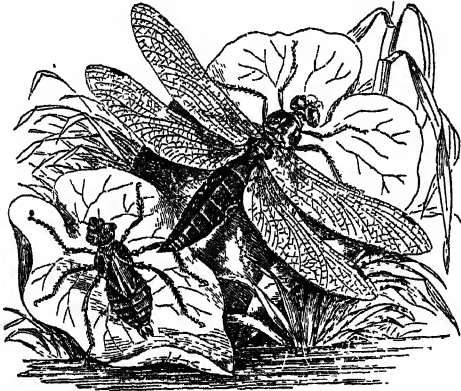

Dragon-fish. See DRAGONET.

Dragon-fly, a name applied to the members of a large family (Libellulidæ) of amphibious neuropterous insects. They are very frequently referred to under the title Odonata. They are well-known insects, conspicuous in their large size, brilliant iridescent colouring, and rapid, restless flight. The slender grace of some forms, especially when half-concealed by the drapery of the wings, has suggested their French title of *demoiselles*, while the Germans hint at a similar comparison in calling them *wasserjungfern*. None the less do they deserve our English name, for they are indeed the dragons and tyrants of the insect world.

Structure.—The body is long and lank; the two pairs of wings are large and almost equal; the head is freely movable upon the thorax; the eyes are usually very large, and are associated with eye-spots; the mouth organs, overlapped by a large upper lip, are very strong, and remarkably adapted for the capture and mastication of other insects.

Habit.—The dragon-flies live near water, in

which they spend their early life. During the day they are ceaselessly active, poising in the air with very rapid vibrations of their wings, or darting over the pools indeed like 'living flashes of light.' They rest upon bushes and the like during the night. Both as larvæ and as adults they are exceedingly voracious, feeding chiefly upon other insects. The two sexes are often seen flying

Dragon-fly and Nymph (*Libellula depressa*).

together in amatory dance, the male clasping his partner's neck with his tail. The colours of the sexes are often different, and the characteristic radiance of the male is in some cases assumed only at reproductive maturity. The males are sometimes larger, never smaller, than the females. The eggs are laid under water, sometimes within aquatic plants. The larvæ live in the water until they are ready for their metamorphosis. Their voracity is very great, and is satisfied by the deft exercise of the peculiarly modified second pair of maxillæ (labium), which can be extended in front of the head like a pair of nippers mounted on a flexible

Metamorphoses of Dragon-fly (*Aeschna grandis*):

a, larva; b, pupa; c, perfect insect issuing from pupa case; d, perfect insect, with wings fully developed.

stalk. This peculiar development is often called the 'mask.' In some young dragon-flies (smaller species of Agrion) there are leaf-like respiratory plates (tracheal gills) at the end of the body; in most the respiration is effected by a rhythmic water-current in and out of the rectum, on the walls of which there are numerous plates abundantly riddled by tracheæ. The expulsion of the water is strong

enough to drive the larva slowly onwards. Before the final moult, the larva creeps up the stem of some water-plant, and rests for a while. Then 'an inner impulse rends the veil of his old husk, from head to tail come out bright plates of sapphire mail.' The wings are first small, soon 'grow like gauze,' and are perfected in the using. Tennyson's well-known description of the metamorphosis is vividly accurate.

Forms.—The family is widely distributed, but most abundant in tropical countries. Yet the exotic forms do not surpass the splendour of some British species. There are three sub-families: (1) Agrioninæ (e.g. Agrion, Calopteryx); (2) Aeschninæ (e.g. Aeschna, Gomphus); (3) Libellulinæ (e.g. Libellula). There are numerous British species—e.g. *Aeschna grandis*, the great dragon-fly, about 4 inches long, and the smaller *Libellula depressa*. The restless activity, the splendid colouring, the voracious carnivorous diet, are probably associated facts.

Dragonnades, the name applied to the persecution of French Protestants, begun by Louis XIV. in 1681, by quartering dragoons in Protestant villages and houses, and giving up the inhabitants to the outrage and plunder of the soldiery, until they should abjure their faith. Armed expeditions marched through the provinces, and by their prompt measures many heretics were restored to the bosom of the church; and in consequence, on the 22d October 1685, Louis revoked the Edict of Nantes (q.v.), that the good work might be fully accomplished. See CAMISARDS, and HUGUENOTS.

Dragon-root (*Arisema atrorubens*), an Araceous plant, whose acrid tuber is variously used in domestic medicine, especially in North America.

Dragon's Blood is a name which has come down to us from ancient pharmacy in somewhat vague application to a number of resinous substances broadly agreeing in their deep-red or reddish-brown colour and astringent properties, but of very various origin. *Dracena draco*, the Dragon-tree (q.v.) of the Canary Islands, yields on incision or even exudation from the stem or leaves, a variety which was formerly of commercial importance, and which is found in the prehistoric Guanche graves, apparently as an accessory of the embalming process. A more important variety is that obtained from the fruits of *Calamus draco*, an East Indian palm. The Red Sandalwood (*Pterocarpus santalinus*, a papilionaceous tree) is another East Indian source, while its West Indian congener, *P. draco*, is of considerable importance. The allied *Dalbergia monetaria* of Guiana, and the Mexican *Croton draco*, must also be mentioned. In Australia the resin of *Eucalyptus resinifera* has also acquired the same name. On account of its colour and astringent properties, dragon's blood has long been used in the preparation of dentifrices; also in alcoholic solution for staining marble, leather, wood, &c.; in oils and turpentine in the preparation of varnishes; and in the illustration of Books (q.v.).

Dragon's Head (*Dracocephalum*), a genus of Labiate, common in gardens, so called from the form of its corolla.

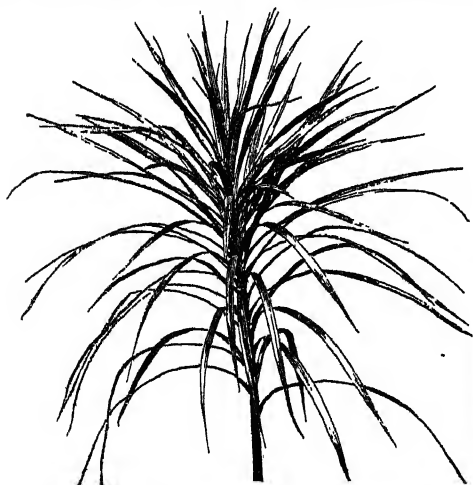

Dragon-tree, a genus (*Dracena*) of Liliaceæ (sub-order Smilacæ), remarkable not only for its resin (see DRAGON'S BLOOD), but also for the indefinite thickening of its stem by means of secondary meristem, and the consequent resemblance in permanence and general habit to a dicotyledonous tree. The examination of a microscopic section of a young stem, however, shows that the thickening arises not as in dicotyledons or conifers through the activity of a surviving tract of embryonic tissue between the wood and bast of the fibro-vascular bundles—but in an essentially distinct and

simpler manner. The stem is at first normally monocotyledonous in structure—i.e. with closed scattered bundles of the ordinary type. The secondary meristem, formed from the cortex, lies wholly outside these, and grows steadily outwards,

Dragon-tree (*Dracena Draco*).

depositing new bundles on the inner side alone (see MONOCOTYLEDONS, STEM). The growth is slow. The great dragon-tree (*D. Draco*), of Orotava, Teneriffe, famous through the description of Humboldt and other travellers, was about 75 feet high, 50 feet in girth, with an internal cavity about 10 feet in diameter. Not simply was it of almost as vast size when the islands were discovered in 1492, but calculations, based on the observed rate of growth of younger trees, carried it back to a probable age of from five to six thousand years. Unfortunately it was blown down by a storm in 1808. Species and varieties of *Dracena* are in great and increasing esteem as foliage plants. *D. marginata*, *stricta*, &c. may be mentioned as old favourites, but a due conception of their

Branch of *Cordyline* (*Dracena*) *australis*.

importance may be best obtained by reference to florists' catalogues. Species of the allied genus *Cordyline*, especially those from New Zealand, are sufficiently hardy to be planted out of doors in summer. *C. terminalis* is used for hedges in the East, and boundary marks in the West Indies, on account of its conspicuous red foliage.

Dragoon, a cavalry soldier who is armed with an infantry firearm, and trained to fight on foot as well as on horseback. The name was derived from

the short musket carried by Marshal Brissac's horsemen in the 16th century, which suggested a fire-spouting dragon. Dragoons were originally intended to act as mounted infantry, and in order to make them more efficient in that capacity, the Russians in 1875-80 armed theirs with the long rifle. In the British army all Cavalry (q.v.) now carry rifles (instead of carbines), but the name dragoon is given somewhat arbitrarily to certain regiments. After the Crimean war, the so-called *light* dragoons were changed into hussars, leaving three regiments of dragoons, seven of dragoon guards, and the three cuirassed regiments of household troops. Six of these are classified as *medium*, and the remainder as *heavy* cavalry, but the men and horses are all big, as compared with those of hussar and lancer regiments. The weights carried by the horses on the march are 19 stone 4 lb. for dragoons, 18 stone 10 lb. for lancers, and 18 stone for hussars. The oldest dragoon regiment is the Scots Greys, established 1683.

Draguignan, the capital of the French department of Var, on a tributary of the Argens, and at the base of the wooded Malmont (2151 feet), 51 miles by rail NE. of Toulon. It has a college, and manufactures of leather, silk, soap, &c. Pop. 10,000.

Drainage is the art of carrying off water from the soil and subsoil of land by means of open or closed drains or trenches; the term, however, is generally understood to apply to closed drains. By its means the fertility of wet land has been greatly increased, and the climate of districts which were before wet and swampy very much improved. When the drains are put in every six or ten yards, it is called *furrow* or *frequent* draining.

The vast amount of capital which has been expended in drainage since the development of the improved methods of draining attests its utility and necessity. Before the introduction of furrow-draining, stiff and tenacious clays were of comparatively little value. They were cultivated at much expenditure of labour, and the crops which grew upon them were influenced to an exceptional extent by the variations of the seasons.

Drainage by open ditches was no doubt the first mode of freeing land from superfluous water. The Roman agricultural writers mention the good results arising from covered drains, formed of wood and other substances, which served so far to render the land dry. In the 18th century, a large extent of clay-land was drained at narrow intervals in Norfolk and Essex, by putting in brushwood and even straw in the bottom of the drains. The progress of draining, which is now regarded in many soils as essential to economic culture, was slow and partial, until James Smith of Deanston, in 1823, reduced the practice to a system, and showed the principles upon which its efficiency depended. Through the exertions of this advocate, furrow-draining soon became a *sine quâ non* in the culture of clay-soils or indeed most soils, in moist climates.

On ordinarily level fields, the line of greatest fall is usually chosen as the best for cutting drains. On steep slopes, where the excessive water is generally due to springs, the best results are obtained by oblique drains, which intercept the line of flow of the water. The minimum fall is about one in five or six hundred, though twice this amount, or, say, three inches per chain (22 yards) is allowed wherever possible. The smaller drains are usually conducted into larger or *main* drains, instead of each discharging its quota of water into the open ditch. This is rendered necessary, as the mouths of the smaller drains would be more liable to be choked up by the growth of weeds;

while the collecting of water into main drains secures a fuller flow to sweep out any matters which might accumulate where the discharge was small. Moreover, the less of the action of the air in the drains the more efficient they are.

The most efficient, and at the same time most cheaply cut drain, is one represented at fig. 1.

Fig. 1.

It is made so that a pipe of a cylindrical form may be laid along the bottom, which need be of no greater width than what is necessary to allow of the pipes being properly laid. Drains of this form are cut with a set of spades which are of different widths—the broadest being used for taking out the top, and the narrowest for the bottom. The work of forming pipe-drains is now accomplished in some cases by mechanical *tractor-ditchers*, which cut the drain and lay the pipes in one operation. These machines are in common use in the United States, and have been tried successfully in this country.

Before the general use of pipes, stones were the common materials with which drains were formed. Smith of Deanston recommended that they should be broken so small, that they might pass through a ring two inches and a half in diameter. From nine inches to a foot in depth was the quantity which was commonly put in. Where stones can

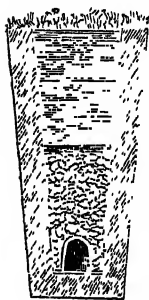

Fig. 2.

be easily got they are still preferred to tiles, as cheaper, and if well put in, more efficient and durable; where any considerable amount of casting is involved, however, the additional labour charge will be greater than the cost of tiles. In constructing stone drains a good plan is to set a pretty large block at each side of the bottom of the drain, and then use a third as a sort of wedge. A coating of smaller stones is surmounted by turf.

When tiles and pipes were first used, it was even thought necessary to have some gravel, or small stones, placed above them in the drains, for the purpose of enabling the water to find its way into them, as seen at fig. 2. It was soon found, however, that tile drains were quite as efficient without any stones or gravel; and that they were less liable to be choked up, as the clay or earth acted as a filter in preventing the intrusion of any kind of solid matter.

Many kinds of tiles and pipes have been tried, but the cylindrical form is most used. At one time, a bore in the pipe of an inch in diameter was thought sufficient, but $2\frac{1}{2}$ or 3 inch pipes are now preferred. Theoretically a $1\frac{1}{2}$ or 2 inch tile is sufficient to carry off the water from such an area as a drain is ordinarily required to serve; but larger pipes are much less affected by slight displacement or by the accumulation of silt, and hence remain efficient for a much longer period. Drain pipes are usually made about 15 inches in length. In some cases a *collar* is used to insure the complete continuity of the drain. The *collar* is a short length of circular tube which loosely embraces the two pipes and thus covers the joint. This *collar* was at one time thought quite essential for the durability of the drain, but it has been found in practice that well-laid pipes will work efficiently and endure satisfactorily without them. And, therefore, as they increase the cost considerably they are not now so largely used. In soft mossy or clayey subsoils, semi cylindrical tiles called *muggs* have been laid on lath, with the bend up.

Smith at first advocated the making of drains from $2\frac{1}{2}$ to 3 feet deep, at intervals of from 10 to 40 feet. Experience has shown that depth and

width must vary with the nature of the soil. On stiff clays the best depth is probably about 30 inches, with about 18 feet between drains. The lighter the soil the deeper may the drains be and the wider apart, but even on sands 3 feet 6 inches and 30 to 36 feet are regarded as about the maximum depth and distance apart respectively.

The principal advantages of drainage are, the deepening of the staple soil, and rendering it more friable, so that a superfluity of water, which would cause the formation of those chemical compounds that are found in stagnant water, is prevented. The greater depth of mould, and more perfect culture, render the soil more absorbent of moisture in dry weather. As crops can usually be sown sooner on drained lands, they also ripen earlier, and produce more abundantly. In short, while drained land obtains a greater capacity for moisture and manure, it imparts to plants greater capabilities for economically working up the materials which they find in the soil and atmosphere, seeing they are maintained in the most healthy conditions of growth.

Drainage in its various forms has, as is well known, not only improved the fertility and value of land in Britain, but materially changed the aspect and climate of large districts which before suffered from the wet, swampy character of the surface soil. Mosses and wet rushy lands have been transformed into dry and productive fields, while by the removal of all superfluous pools, the air is freed from those hovering vapours which are injurious to general amenity and salubrity. To the farmer, the more immediate advantage of drainage consists in that rapid running off of the water which falls as rain, so as to admit of working lands without any undue delay, while natural springs and dampness, from whatever source arising, are also run away with wonderful success. Drainage according to the principles first established by Smith of Deanston is now practised in most parts of the world. Recent advances in technique are mostly due to the United States, where within the past few decades very large areas have been brought under cultivation by draining.

See WASTE LANDS, BEDFORD LEVEL, BEOTIA, BOG, FUCINO (LAKE OF), HAARLEM LAKE, HOLLAND, MARFOTIA, MEXICO (CITY), POLDER, ZUIDER ZEE, &c; also IRRIGATION. The drainage of houses and cities will be considered at SEWAGE.

Drais VON SAUERBRONN, BARON KARL (1785-1851), inventor of the draisine or draisienne, a form of dandy-horse (see CYCLING), was director of waters and forests for Baden, and wrote on forestry.

Drake, SIR FRANCIS, the greatest of the Elizabethan seamen, was born near Tavistock, most likely in 1540. His father was apparently in humble life, is said to have had twelve sons, and to have been obliged for conscience' sake to take shelter in Kent. The boy was apprenticed at an early age to the master of a small vessel, who bequeathed it to him, after which he followed the coasting trade some years. 'But the narrow seas were a prison for so large a spirit, born for greater undertakings,' and by 1565 he was voyaging to Guinea and the Spanish Main. In 1567 he commanded the *Judith* of 50 tons in his kinsman John Hawkins's ill-fated expedition; next made in 1570 and in 1571 voyages to the West Indies with a view to find intelligence how to make good the losses he had suffered from the Spaniards at that time. Next in May 1572 he equipped two small ships, the *Pasha* and *Swan*, with but seventy-three men, landed at Nombre de Dios, 29th July, and beat off the Spaniards after a short struggle, in which he was severely wounded. His own fainting from loss of blood alone prevented the 'Treasure of the World'

from being carried off. In this audacious expedition Drake further burned Porto Bello, captured and destroyed many Spanish ships, crossed the isthmus to the highest point of the dividing ridge, where, climbing a tree from whose tops the guides told him both seas could be seen, he gazed upon the vast waters of the South Seas, and with that touch of romantic enthusiasm that redeemed all his piracies, 'besought Almighty God of His goodness to give him life and leave to sail once in an English ship in that sea.' Drake arrived in Plymouth on Sunday, 9th August 1573, during sermon-time, when the news of his return 'did so speedily pass over all the church, and surpass their minds with desire and delight to see him, that very few or none remained with the preacher, all hastening to see the evidence of God's love and blessing towards our gracious queen and country.'

In 1577 he fitted out another small squadron of five vessels, the destination of which was kept secret, consisting of his own ship the *Pelican* of 100 tons, the *Elizabeth* of 80 tons, and three smaller vessels, and with these sailed from Plymouth on the 13th December. One Thomas Doughty was tried and executed at Port St Julian for an attempt to stir up a mutiny, and on the 20th August, the squadron, now reduced to three ships by the burning of two, entered the Strait of Magellan, and here Drake changed his own ship's name from the *Pelican* to the *Golden Hind*. In sixteen days they made the passage, then followed violent tempests for fifty-two days, during which the *Marigold* foundered with all hands and the *Elizabeth* parted with the admiral and resolved to return home. She reached England, 2d June 1579. Drake was driven far to the southward, but at length was able to alter his course and steer northwards again. At Valparaiso he provisioned his ship from the Spanish storehouses, reached Callao on 15th February 1579, found a rich prize off Cape Francisco (March 1) and another on 4th April. Drake now determined to return home by crossing the Pacific. He touched land at a creek on the northern side of the Golden Gate, then for sixty-eight days together had no sight of land until he made the Pelew Islands. After refreshing three weeks at Ternate, and a thorough refit on the south-west coast of Java, he held for the Cape of Good Hope, and arrived in England, 26th September 1580. The queen, in the face of Spanish protests, was at first uncertain how to receive Drake, but at length (April 4, 1581) paid a visit to his ship at Deptford, and knighted him on its deck.

In the autumn of 1585 Drake sailed with a fleet of twenty-five ships against the Spanish Indies, harrying Hispaniola, Cartagena, and the coast of Florida, and after great sufferings from sickness, brought home the 190 dispirited Virginian colonists, with tobacco and potatoes (28th July 1586). Early in 1587 he set sail with a strong squadron to cripple the king of Spain in his own seas, and retard his preparations for invasion—a sport which he called 'singeing the king of Spain's beard.' Sailing right into the harbour of Cadiz, he sank or burned as many as thirty-three ships, and made his way out unscathed. The seeming recklessness of his tactics was no devil-may-care bravado, but due to consummate seamanship no less than promptitude and courage. Drake next sailed to the Azores, capturing a rich homeward-bound Portuguese carack worth £100,000. In the face of the impending struggle for which Philip II. had long been preparing, his persistent plan was to follow up the policy of harassing the enemy on his own coasts—"to seek God's enemies and her majesty's where they may be found." In a letter to the reluctant and parsimonious queen not three months before the actual sailing of the Armada, he

reiterates his advice 'to encounter them somewhat far off, and more near their own coast, which will be the better cheap for your majesty and people, and much the dearer for the enemy.' There is no doubt that Drake's plan was the best, and had not the elements themselves fought for England, the issue might have been vastly different.

Drake's division in the three-fold arrangement of the English fleet was at first stationed off Ushant, until all the ships were blown together to Plymouth by the same storm that carried the Spaniards across the Bay of Biscay. Here, on the Hoe, the admirals and captains were playing the famous game of bowls, when the news was brought that the enemy was off the Lizard. Howard was eager to put to sea at once, but Drake would first finish the game, saying 'there's plenty of time to win this game, and to thrash the Spaniards too.' The story, whether true or no, is in perfect keeping with the character of the man. Early next morning the battle began, and raged along the Channel throughout the week. Drake's consummate seamanship and audacious courage covered him with fresh glory, and inspired new terror in the Spaniards. He captured the *Rosario* off Portland, whose captain, Don Pedro de Valdes, ransomed himself with £3000 three years later. On the 29th July occurred the final action so disastrous to the Spaniards, after which they came to their fatal determination to return to Spain round the Orkneys. Two days later Drake wrote to Walsingham: 'There was never anything pleased me better than the seeing the enemy flying with a southerly wind to the northward. God grant you have a good eye to the Duke of Parma, for with the grace of God, if we live, I doubt it not, but ere it be long so to handle the matter with the Duke of Sidonia, as he shall wish himself at Saint Mary Port among his orange trees.' It was not long before want of ammunition compelled Drake and Howard to fall back from the chase, but the storms of the northern seas took up their work and swept the Spaniards to destruction. Drake's fears that the Armada might refit in Denmark were happily frustrated, and the liberties of England were saved. Next spring a great expedition under him and Sir John Norreys sailed for the coasts of Spain and Portugal, but had little success beyond the damage inflicted upon the Spanish shipping, while sickness and actual hunger carried off thousands on board the crowded and ill-victualled ships. Drake spent his next few years in peaceful labours on shore, bringing a new water-supply to Plymouth, and representing the town in parliament. In August 1595 he sailed from Plymouth on his last expedition to the West Indies. Ill-fortune followed the fleet from the beginning; Hawkins, the second in command, died off Porto Rico in November, and Drake himself fell ill from dysentery and died off Porto Bello, 28th January 1596. His body was put into a leaden coffin and next day committed to the deep; as an anonymous poet quoted in Prince's *Worthies of Devon* said:

The waves became his winding-sheet; the waters were his tomb; But for his fame, the ocean sea was not sufficient room.

See the *Life* by Barrow (1843); Froude's *English Seamen of the 16th Century* (1895); Corbett's short *Life* (1890); his elaborate *Drake and the Rise of the Tudor Navy* (2 vols. 1898); *New Light on Drake* (trans. Mrs Nuttall, 1914).

Drake, FRIEDRICH, a celebrated German sculptor, born at Pymont, 23d June 1805, and trained under Rauch of Berlin. Among his principal works are 'The Eight Provinces of Prussia' (colossal allegorical figures), and a 'Warrior crowned by Victory,' which is reckoned one of the masterpieces of German sculpture. But Drake owes his celebrity chiefly to statues, busts, and medallions,

and there are few of his great countrymen of whom he has not preserved a marble memorial. His statues of Schinkel, the two Humboldts, Rauch, Oken, his colossal statues of Frederick-William III., and William I. at Cologne, deserve especial mention; as also the busts of Bismarck and Moltke. Drake, long professor of Sculpture in the Academy at Berlin, died 6th April 1882.

Drake, NATHAN, Shakespearian scholar, was born at York in 1766, graduated M.D. at Edinburgh in 1789, practised his profession for forty years at Hadleigh, in Suffolk, and died in 1836. He published several collections of more than average essays, but his name now lives only in his learned and valuable *Shakespeare and his Times* (2 vols. 1817). A supplementary work was entitled *Memorials of Shakespeare, or Sketches of his Character and Genius by Various Writers* (1828).

Drake, SAMUEL GARDNER, American antiquary, was born in Pittsfield, New Hampshire, in 1798, and in 1828 established in Boston what is said to have been the first antiquarian book-shop in the United States. He published a number of reprints and of valuable works relating chiefly to the early history of New England. He died 14th June 1875.

Drakenberge, or **DRAKENSBERG** ('Dragon Mountains'), the general name given by the Dutch colonists to the range of mountains in the east of South Africa bordering the plateau. From about 29° S. lat. the three chains which form the southern portion unite and extend north-eastward in one mass, whose highest points are Cathkin Peak (12,000 feet), Mont aux Sources and Giant's Castle (11,000). The range is crossed by Van Reenen (5415) and De Beers (5635) passes.

Dram. See **DRACHMA**.

Drama, a Greek term literally signifying action, and applied to that form of literature which serves as text for what in the same sense is called acting, that is to say, the performance before spectators of an 'acted' and spoken imitation of scenes of life. The following article discusses merely the drama as limited to a class of literary productions, the art of acting and the history of theatrical performances being reserved for the article **THEATRE**. Nor will any attempt be made here to give a detailed account of the work of distinguished dramatists, which will be found from *Æschylus* downwards under the proper heads. We shall here confine ourselves to the survey of the general characteristics of the successive schools of literary drama in Greece, Rome, the middle ages, and modern Europe. In some oriental languages the drama holds a not unimportant place, but the written examples are not supposed to be of very great antiquity, and in any case they are, as drama, much inferior in interest to the European examples.

No specimens of the earliest age of Greek drama, that is to say, of the compositions, either purely dithyrambic or consisting of choric songs interspersed only with monologue, which are supposed to have prevailed in the infancy of the art, now survive, nor can much (if anything) be said to be known about them. Our earliest examples, the dramas of *Æschylus*, whose chief predecessors were *Phrynichus*, *Chœrilus*, and *Pratinas*, exhibit the drama in a very advanced condition, so far as the particular style goes. The dialogue, though in the earliest examples not more than two actors were permitted to be present as speakers on the stage at the same time, is managed so as to unfold a varied and completely dramatic story; while the chorus, either as a whole or subdivided into sections, performs its lyrical odes, and, when necessary, takes part by its leader, and rarely by other members,

in the actual dialogue. The almost immediate addition of the tritagonist or third speaking actor, which, whether due to *Æschylus* himself or not, appears in his later plays, is practically the only change of importance subsequently made; and this was not as a rule further extended in Greek tragedy, that is to say, in the works of the three great writers, *Æschylus*, *Sophocles*, and *Euripides*, of whose works we possess, though unfortunately but a very small proportion, yet a part considerable when considered by itself. Very rarely the *quarta persona* or something like him appears, but this is a mere exception, and unimportant. We have thus the very remarkable phenomenon of an extremely artificial and complicated art, which seems almost within a single generation to have attained its furthest possible development. The actors—who sometimes make a tolerably numerous list, though not more than three may, as a rule, figure on the stage at once, except as mute persons—conduct the dramatic performance strictly so called by dialogue, gesture, and a certain amount (though less than on the modern stage) of action. The chorus, in its odes, explains incidents which assist if they are not necessary to the comprehension of the action, moralises on this same action, and occasionally takes part in it, giving in its specially choric utterances a certain heed to the keeping up of the sacred character which (see **THEATRE**) seems to have been associated with the origin of dramatic performances, if not of dramatic writing, in almost all countries.

The plays written for this disposition of company were for the most part, if not always, arranged in trilogies or sets of three, followed or not by a fourth play of a quite distinct and comic or satiric character. Whether there was any original reason for this arrangement, except that of convenience, is not known; but the reasons of convenience, when the limitations of the drama are considered, are obvious. For with each new play the restrictions of the *Unities* were relaxed, or rather disappeared altogether, and a fresh time, a fresh place, and an only distantly connected scheme of action could be entered upon. These famous *Unities*, which at various times in the history of literature have been the subject of the fiercest discussion, appear to be less *a priori* rules which the authors had before them and obeyed, than generalisations from these authors' practice, which later critics and students deduced and formulated. Some slight and some serious deviations from them, as in the case of the change of scene and the lapse of time in the *Æumenides*, have been detected. But generally speaking, the *Unity of Time* rules that not more than twenty-four hours are to be supposed to pass; the *Unity of Place*, that the scene shall not be changed; and the *Unity of Action*, that nothing like an independent underplot shall be permitted, every incident, and practically every speech, being subordinated to the main argument. On the whole, these strict conditions are very strictly observed. When they were taken with the exact and (in the case of the choruses) intricate metrical structure of the verse, they set Greek tragedy at the head of all literary performances as an example of exquisite symmetry of form, of severe but not overdone proportion. It is, however, almost as remarkable that, at least in *Æschylus* and *Sophocles* (for the 'Third Poet' is in this respect far inferior), no deficiency of dramatic interest attends this severity of form. Even in the earliest examples the metrical arrangements—iambic trimeter and trochaic tetrameter for the dialogue, anapaestic dimeter for part of the chorus work, and a vast variety of apparently lawless but in reality most correctly regulated rhythms for the rest—are consummate. The magnificent poetical quality of *Æschylus*, the sense of overmastering fate with which he

manages to charge all his drama, and the perfect humanity of Sophocles, relieve their work entirely from the charge of sterility which has been brought against more modern imitations of their form. No other general remark is required as to Greek tragedy, except that its subjects, as we have them, were limited to poetical and heroic tradition, with a certain admixture of what in modern literature we should call the chronicle-play, or drama of contemporary event. The only extant example (for we know that there were others) is the *Persæ* of Æschylus; an exceedingly interesting play, because it shows the ease with which the Greeks could achieve what has baffled almost all moderns.

We are even more scantily furnished with examples of Greek comedy. Indeed, we have no complete specimens, except (very fortunately) the work of the acknowledged chief of the style, Aristophanes. Yet we know that not only the two poets whose names are indissolubly coupled with his—Eupolis and Cratinus—but many others, illustrated what is called the Old Comedy, in which persons and political events of the day were satirised with a fearlessness never exceeded, rarely equalled, and likely to provoke (as we know it did provoke) violent reprisals. In addition to this we have in the *Cyclops* of Euripides an example, though probably not a very typical example, of the satyric play which finished the tragic trilogy, making with it a tetralogy. Of the so-called Middle and New Comedies which succeeded the Old, and which successively attenuated its bold personal attack into a weak comedy of manners, we have no specimens at all, though we can judge to some extent of their nature by the Latin imitations which have survived. But the great name of Menander, although illustrated at the present day only by the merest fragments, survives with a reputation in the New Comedy only inferior to that of Aristophanes in the Old. Of the two later kinds, the best that can be said is that the Greek genius, with its almost unflinching peculiarity of pushing such kinds as it attempted at all to their utmost capabilities, elaborated pretty completely the stock comedy, or comedy of certain general types of character; and that great as have been the changes of manners, no one, with the single exception of Molière, has made much original addition thereto since. Of the Old Comedy much more might be said, though we must for the present chiefly refer the reader to the article ARISTOPHANES. It must suffice here to say that to an abundance of wit in dialogue, not excelled even by Molière and Congreve, Aristophanes joined poetical faculties to which neither of these great writers can make the faintest pretence, a bold and thorough grasp of politics, which he exhibits especially in the parabases or direct addresses to the audience, and a quality of humour in the English sense, which no other ancient has approached. If it were not for the limitations of the female characters which Greek manners necessitated, Aristophanes would probably have been the equal of Shakespeare in the comedy of which *As You Like It*, *A Midsummer Night's Dream*, and *Much Ado About Nothing* are examples that never can be excelled, and that have never been equalled in their own way. As it is, the *Knights*, the *Clouds*, and the *Frogs* deserve exactly the same description.

It was thus the fortune of this extraordinary people, in the literary practice of a very brief period of years, to leave examples ranking to this day in the first class of the literature of the world, and serving as the basis of a set of critical rules which, followed not always with knowledge, governed literature until but the other day. Their immediate disciples and successors, the Latin poets, added but little if anything to the

general system of drama, and their work has been transmitted to us in a most fragmentary condition. Latin tragedy of the regular kind may be said to have perished *en masse*, with a singular and very important exception. By very great good luck the comic work of Plautus and Terence, which we possess in good measure, not only represents for us the two great divisions of the Greek comic drama which, as we have said, are in Greek utterly lost, save in the most insignificant fragments, but exhibits in its own characteristics a very important difference of feature. The work of Terence is distinctly literary work, probably coming as near as the author could manage to its Greek originals. The work of Plautus, though hardly less indebted in many cases to those originals for plot and incident, displays a very strong infusion of vernacular character—the character, as we may judge, of the lost Atellan farces, and the character generally of Roman humour. The fault of Terence is, that he is thin; the fault of Plautus is, that he is coarse; and as far as we can judge from evidence but little more abundant than the fragmentary bones of extinct animals, these two defects may or must have been characteristic of the Roman drama generally. Of the tragedy, as we have said, at least of the early tragedy of Pacuvius, Accius, and others, it is very hard to judge at all; but there seems good ground for regarding it as a feeble copy of Greek, probably with attempts to make up for feebleness by rant of diction. The very remarkable group of works which are attributed to Seneca, whether to L. Annaeus Seneca, the philosopher, or another of the same name, but which at least date with certainty from the imperial period of Rome, stand by themselves. They represent various styles, the heroic and so to speak romantic kind, the kind of already somewhat distant history, and the kind of contemporary interest. They are pretty obviously what we call 'closet drama,' that is to say, whether they were ever acted or not they were clearly written as writing, and not merely as playwright's work. They have, with much literary ability, a certain absence of *vis vivida*, though this absence has often been exaggerated. But where they are so very important is in this—that they, far more than the great early plays of Greece, determined the tragic revival of the Renaissance. It is Seneca, not Æschylus, not Sophocles, not even Euripides, that the experimenting dramatists of Italy, of England, of France most of all, follow when they attempt the regular tragedy in the 16th and 17th centuries. Seneca (not any of 'The Three') is directly responsible for Corneille; and if England had not set her face against it, it was Seneca who would have been reproduced in England by Sackville and Norton, by Edwards, by Daniel, by the Countess of Pembroke, and others; as he was in France by Garnier and Montchrestien; as he had been in Italy by Trissino.

It is, however, evident that the drama, as distinguished from pantomimic shows, beast-fights, and the like, was not a favourite kind of literature either with the Romans or with the inhabitants of the Roman empire; and this partly accounts for the ferocity of the early fathers of the church against the theatre, a theatre which was for the most part occupied by things very different from the *Antigone* or the *Eumenides*, by things compared to which even the *Lysistrata* would appear innocent. It also accounts for the small attraction which dramatic writing seems to have had for the authors of the empire. Lucian, for instance, ought to have written admirable plays; but he has left us not one. And by degrees, from the combination of all the causes hinted at and others, drama seems to have become practically extinct. The early dark

ages produce nothing worth speaking of, while the Terentian comedies of the nun Hrotswitha stand by themselves, and are little more than literary *pastiches*. When the drama reappears, the re-appearance marks a genuine new birth. As before, this birth was connected with the offices of religion, though the precise extent to which this connection reached is a matter of great, and (if one who has given some attention to it may say so) of never-to-be-settled debate among the learned. It is sufficient to say that about the 11th century in France appear the beginnings of the famous miracle or mystery play, which has sacred subjects only, is in its earliest forms very short, and consists for the most part in the representation 'by personages,' as the vernacular phrase went, either of scenes from the Bible or of legends of the saints. There is no chorus in the proper classical sense, though rarely there are approaches to it. The metre is usually rhymed octosyllabic couplets, with a few more complicated schemes thrown in, and the dramatic action, though genuine and complete as far as it goes, is very simple. This kind, which is still represented in sophisticated forms by the famous Ammergau passion-play, was extremely popular; and though later in other countries than in France, has tolerably early representatives in most of them, especially in Germany and England. France, however, was its special home, and the liking of the people for these at first sacred dramatic performances seems to have branched out there into a variety of secular kinds, which, so early at any rate, are not paralleled anywhere else. As early as the 13th century a single French author, Adam de la Halle, originated, so far as is known, two important styles, the comic opera (in *Robin et Marion*) and the modern comedy, in the half autobiographic composition called the *Jus* [*Jeu*, 'game'] *Adam* or *Jus de la Fenille* ['of the booth']. Of these compositions the former has hardly a trace of roughness, while the latter contains no hint of classical inspiration. By the 14th century probably, by the 15th certainly, France had added to the miracle or mystery, which branched out into the 'profane mystery' or chronicle-play dealing with current events or ancient history, not merely the *farce*—the dramatisation of the earlier verse *fabliau* or comic story, and the 'Morality'—an allegorical play of virtues, vices, and the life of man generally, to which the general medieval passion for allegory gave great vogue; but also the *sottie* or political farce, something like though not in the least imitated from the Athenian comedy of the old type, as well as not a few minor varieties. The passion for dramatic entertainments was very great; societies or guilds existed for their performance, and it was not unusual for days, or even weeks, to be occupied in a single display. We still have mysteries extending to fifty thousand lines, and altogether it may be said that this passion for scenic representation, as it has been always more widespread, developed itself earlier in France than in any other European country. It is not a little striking also, that in the south-west corner of France the morality still substantially survives in the Basque *pastorales*.

In no other country than France, however, did the tastes of the middle age receive a more complete check and change at the Renaissance; and as this change was partly connected with the importation of Spanish and Italian fashions, it may be desirable very briefly to sketch the great and interesting dramas of the two peninsulas before recounting the later history of dramatic literature in France.

Great as are the performances of Italy in European literature, her achievements in drama, even to these late days, are of little moment, when

compared with the towering fame of Dante and Petrarch, of Ariosto and Tasso. Her chief influence was to direct France into following the Senecan tragedy, and, through a writer who took the French name Laivey, but who was really a Giunto, the Terentian comedy somewhat relaxed. No Italian medieval work for the stage is in the least remarkable; but as soon as the Renaissance dawned, divers writers, Trissino especially, adopted the stiff form of tragedy already referred to, and persons no less notable than Macchiavelli, Cardinal Bibbiena, and the great Ariosto, attempted comedy. Before very long, however, the lyrical drama, which under the name of opera, was from Italy to conquer Europe, pushed drama proper much out of favour. It was a little restored by a group of learned writers in the late 17th century, the chief of whom was the Marquis Maffei, a soldier, an antiquary, and a playwright, whose *Merope* (1714) Voltaire deigned to follow very closely. Goldoni and Gozzi started a school of comedy which was to a great extent a reflection of national manners, and has a real distinction. Whether as much can be said of the formal lyric dramas of Metastasio in the middle, or of the much vaunted tragedies of Alfieri at the end of the 18th century, is perhaps a matter of taste. There are some who hold that in no poet is the worse side of the so-called classical drama more apparent than in the second of these writers. But neither Alfieri nor any other writer of Italy has succeeded in drama, since the school of Venetian comedy above mentioned, in striking what may be called an original note, though during the 19th century Manzoni and others have attempted the style. In general literary history the dramatic achievement of modern Italy is the determination of France into the classical model.

Very different is the record of Spain. It is an infinitely more germinal history than that of Italy, though unluckily it is even shorter. The strong, though apparently not sustained originality of Spain, showed itself nowhere more than in her drama. No medieval performances of much merit are cited by historians; but instead of being diverted by the Renaissance into a mere following of classical models like France and Italy, the Spaniards showed independence almost equal to, and an immediate command of form far greater than, that of the English theatre itself. In part they continued the religious tradition by their *autos*; in part they diverged into romantic drama of the freest kind; and they almost invented for themselves the comedy of fashionable life and intrigue which was imitated freely by all the great playwrights of the 17th century in other countries, and which is famous for its prodigal waste of ingenuity, if also for its rather penurious thrift of probability. They furnished in the Don Juan (q.v.) story one of the two or three most fertile dramatic motives of Europe, and in Lope de Vega and Calderon they produced dramatists not equalled in fertility anywhere, and surpassed in genius only by the greatest names of the world. Half at least of the most famous plays of the French classical period are more or less directly borrowed from Spain, and England also pillaged in her turn. But the period of Spanish dramatic productiveness was unfortunately as short as it was brilliant; and it has had no revival. What the Spaniards did for Europe in dramatic matters was to develop a fertile and powerful drama in complete defiance of classical traditions, to show the dramatic possibilities of the supernatural, and to push almost to the farthest extent the comedy of ingenious surprises, and 'wheels within wheels.' The merits of this drama are the more remarkable that its most usual metrical vehicle, the trochaic

dimeter, does not seem beforehand very well suited for the purpose.

The first influence which impelled men to the creation of the new drama in France came, as has been said, from, or rather through Italy; but it was necessary before dramatic work of the first class could be produced, that the Spanish influence should also be felt. It is at first sight surprising that so vigorous and racy a kind as the indigenous comic drama of France had already shown itself to be, should be pushed out by a merely learned and literary importation. Nor in fact was it so, except in Paris and one or two other centres of culture, while even there it was not completely banished until the genius of Molière, which long exercised itself in something very like the ancient farce, effected a combination between the vernacular, the Terentian, and the Spanish comedy. In tragedy, however, the school commonly called the *Pléiade*—i.e. the poet Ronsard and his set—effected a complete revolution or innovation, following the Senecan model. The two plays of Jodelle, a member of the *Pléiade* itself, *Cléopâtre* and *Didon*, set the example of a tragedy exactly resembling those attributed to Seneca, with choruses and all apparatus complete. This style of tragedy was continued for many years, and was cultivated by at least two poets of the greatest talent, Robert Garnier and Antoine de Montchrestien; but the choruses were by degrees dropped as unsuitable to modern audiences. Still the substance of the tragedy remained much the same, even when, in the hands of a later school, of whom Alexandre Hardy was the chief, a great infusion of Spanish romanticism took place. Nor was the scheme much altered, whatever might be the case with the treatment, when Rotrou and Corneille at last formed the French classical tragedy proper. For the details of this reformation, and of the similar, though less strict reformation which comedy, in the hands of Scarron, Corneille, and Molière chiefly, also underwent, reference must be made to the separate articles on Corneille, Molière, and Racine. As produced by these three great men, and by imitators in the second half of the 17th century, both tragedy and comedy assumed shapes which France long retained unaltered, and which for a time gave law and pattern to all Europe except England, and even to some extent there. The tragedy was of the Greek or rather the Senecan kind, without choruses, and with a slight relaxation of some of the minor stringencies, but with the unities for the most part maintained, and with, as a rule, the fortunes of a love affair substituted for the classic themes of fate and inherited doom. The metrical structure was unvarying, alexandrines or iambic trimeters arranged in couplets tipped with *rimes difficiles*, or rhymes as elaborate as possible. Much less restriction trammelled comedy, which accordingly ranks higher. It might be written either in prose or in verse; the unities of place, and even to some extent of action, were neglected or construed loosely. A very great variety of interest and subject matter was admitted, and the elaboration of really witty dialogue supplied endless opportunities of ornament. At the same time, in the hands of Molière nearly always, though less often in those of his followers, the moral or satirical purpose was carefully observed. The reign of these two kinds continued with little interruption, though with great variety, and on the whole constant diminution of merit, till the end of the first quarter of the 19th century. In tragedy, Crébillon the elder succeeded in raising the style to something not far below Corneille's level, while Voltaire, applying his own singularly various and versatile talent to it, and enlarging the range of subject and situation, produced work which ranks as drama,

though not as poetry, almost with the work of Corneille and Racine itself. In comedy, the level continued higher, very excellent work of the Molièresque kind, slightly altered in various ways, being done by Destouches, Marivaux, Piron, and others; while towards the middle of the 18th century, a sort of third or bastard kind, variously called as it approached one extremity or the other, *comédie larmoyante*, or *tragédie bourgeoise*, was introduced by La Chaussée, Sedaine, Diderot, and others. Unlike most bastard kinds this proved fertile, and under the generic name of *drame* may be said to have important representatives at the present day. It tended naturally to emancipate itself from the restrictions of tragedy, and so no doubt helped the great revolt of what is called the Romantic Movement, which about 1830 practically destroyed the old French tragedy, and seriously interfered with the Molièresque tradition of comedy. Here, too, reference must be made to special names—e.g. Dumas, Hugo, and De Musset. It must be sufficient here to say that the alteration has revived the always keen interest of Frenchmen in the drama, and introduced a vast quantity of literary work of much higher value than had been produced in drama since the latter half of the 17th century. France has once more become the central seat of drama in Europe, and foreign nations have been much busier in adapting her productions than in producing original work of their own. At the same time it must be confessed that tragedy proper has continually dwindled, and that even comedy of the higher kind has been somewhat injuriously affected. The chief new growth of value at once literary and dramatic has been in the production of dramatic sketches of various sorts, slight in substance and brief in duration, but admirable of their kind. During the Second Empire an immense popularity was also achieved by comic opera or rather *opéra bouffe* of a not very exalted class, the sprightly music of Offenbach contributing much to this result.

Of the great literary European nations, Germany has on the whole contributed least to the European drama, though one dramatic motive, the Faust story, worthy to rank with that of Don Juan, is due to her, and though at two distinct periods, the middle of the sixteenth and the junction of the eighteenth and nineteenth centuries, the supernatural drama, of which this Faust legend has given the chief example, exercised, mainly on German impulse, great influence abroad. Otherwise the Germans have been, save for one brief period, more remarkable for assiduous cultivation of the art of acting, and the theory of the stage, than for the production of great dramatic work. There is no German drama of European reputation that dates either from the middle ages or from the Renaissance, or from the 17th century; and it was not till the middle of the 18th that Lessing, not so much by his actual dramas as by his critical discussions of the drama and dramaturgy generally, earned for himself a really great place in dramatic history. At the end of that century what has been called the *Sturm und Drang* school flooded Europe for a time with extravagant or sentimental productions of the class of which Schiller's *Robbers* and Kotzebue's *Menschenhass und Reue* ('The Stranger') are the most famous examples in two different kinds; while the first mentioned is perhaps the best, and the second one of the worst in literary merit. Kotzebue, indeed, was a very popular dramatist everywhere for a time. The two great writers, Schiller and Goethe, stand on a different level altogether. The former, calming down from the state of mind out of which grew his *Robbers*, produced a series of plays which to the English taste suffer from a too close approxima-

tion to the French style, while, according to classical standards, they err by dramatic license, but which nevertheless contain much noble poetry and some striking drama. But in this same style Goethe's *Egmont* far surpasses anything of Schiller's, except the splendid chronicle-play of *Wallenstein*, while his *Iphigenia in Tauris* is (except Milton's *Samson*) the only modern classical drama which is really classical, and his *Faust* is not only one of the capital works of European literature, but includes rather than constitutes some of the finest dramatic work to be found out of Shakespeare. The chief vehicle of German dramatic poetry is the same as that of English, the unrhymed iambic decasyllable.

There are more reasons than one for taking the drama of England last, the two most pertinent being that it was, except the German, the last to crystallise itself into a determined form, and that while that form has on the whole maintained itself, each of the influences which have been already discussed in their several countries of origin has successively exercised more or less force there. In England, as elsewhere, the miracle-play existed, and divers collections of it, known as the York, Digby, Townley, Chester, and other collections, have been preserved and published. But these are both later and ruder than the French examples. Nor does the drama seem to have taken in England, until quite the beginning of the 16th century, anything like the various extensions which it received in France. Out of the miracles and Mysteries (q.v.) arose the moralities; between them and the regular drama come the interludes of Henry Medwall and John Heywood (q.v.), and the doggerel of Bale. The great and original school, commonly known as that of the Elizabethan dramatists, did not, however, arise till the last quarter of the century. Among the somewhat amorphous dramatic products which preceded it, without as far as can be seen giving this great group of playwrights much help of pattern or precept, it is usual and proper to distinguish three pieces—*Ralph Roister Doister*, by Nicholas Udall; *Gammer Gurton's Needle*, assigned to Bishop Still; and the tragedy of *Gorboduc*, or *Ferrex and Porrex*, by Sackville the poet and Thomas Norton. The first and second are comedies, or rather farces, the second of ruder type than the first, but both exhibiting a considerable advance from the mere interlude towards comedy proper. The third, composed under the same influence as the drama of the Pléiade, is after the style of Seneca—a style which happily, though more than once attempted in the years immediately following, was obstinately resisted by the English genius, and took no root here whatever. It is not possible to assign any foreign origin to that school of English drama, which, suddenly appearing in the work of the so-called 'university' group, of Marlowe, Greene, Peele, and in a rather different vein Lyly, passed into the far more capable hands of Shakespeare, Ben Jonson, Chapman, Dekker, Beaumont and Fletcher, Webster, Middleton, Thomas Heywood, Massinger, Ford, and Shirley. To indicate even briefly the main characteristics of this drama would overpass the whole limits of this article. Suffice it to say, that allowing for its admitted defects in order, measure, and elaborate finish, as well as in dramatic arrangement and in academically perfect literary style, no drama in the world excels or equals it in the vigorous variety of dramatic character and situation, or in the application of the highest poetry to the purposes of drama. Its desinence is usually fixed at the death of Shirley (1666), but, as a matter of fact, the best plays of the class had ceased to be written even before the closing of the theatres twenty years earlier, as a result of the Puritan hatred for stage plays. By

this time the two great ethical defects of the whole school, the unnecessary horror of its tragedy, and the unnecessary foulness of its comedy, had reached their highest point, while both the dramatic and the poetic quality of its practitioners had sadly fallen off. In particular, the secret of blank verse which had afforded so admirable a vehicle was all but lost before ever the Civil War broke out. Accordingly, when after the Restoration tragedy revived (the staple matter of comedy and its usual manner are so much the same in all circumstances that fewer changes appear therein in every case), it assumed a very different complexion. Partly influenced by the admiration of things French, but more by the fact that Davenant had been enabled by Oliver Cromwell's love of music to introduce even during the Commonwealth a sort of musical drama, there came in what are called 'heroic' plays, the chief formal characteristic of which is that they are written, not in blank verse, but in rhymed couplets. These held the stage for some twenty years or so, their chief practitioner being Dryden, with Crowne, Otway, Lee, and others to back him in tragedy, and Shadwell, Crowne, Otway, Etheredge, Wycherley, and others in comedy. At last Dryden himself, either following or guiding the public taste, returned to blank verse, and produced in it the last really fine examples of English tragedy, properly so called, for the work of Rowe and Congreve in this kind is not noteworthy. The 18th century produced nothing of value, and all the attempts that have been made since at pure tragedy on the English stage have been either merely literary work, or a kind of *drame*, or else performances of scarcely any literary merit but some stage adaptability.

No such fate for a long time befell comedy. It has frequently been held that the Restoration dramatists in the proper sense (for the term is often very loosely used) introduced an entirely new style. It might perhaps be maintained without much difficulty that Etheredge and Wycherley, the two chief writers of the new school, rather adjusted the old humour comedy of Jonson, and the bustling lively comic work of Fletcher, to the change of manners, the greater demand for literary style, and the example of Molière. Following them, in the reign of William of Orange and that of Anne, Congreve, Vanbrugh, and Farquhar carried this altered style to almost its highest possible perfection. All their work, as well in the earlier as in the later examples of it, was, however, marred by a singular brutality of thought, even where (which was rarely the case) this brutality of thought was not coupled with an equal coarseness of language. For a long time the public demanded, enjoyed, or tolerated this; but at length taste changed, and the famous paper war, which had begun with Jeremy Collier's attack on the stage, undoubtedly did much to purify English comedy. But it did not strengthen it, and nothing in the way of comic dialogue has since been produced which equals the best scenes of Vanbrugh and Congreve. It is, however, justly complained that this liveliness of dialogue is frequently studied at the expense of the verisimilitude and progress of the action. No similar complaint had to be made, though much comic work of merit was produced, until the time of Goldsmith. His two masterpieces were followed at no very great interval by the famous work of Sheridan, in which the methods of what may still be called Restoration comedy are adapted to altered tastes in literature and morals with surpassing skill. Sheridan is the last great name in the English drama, and though, especially of late years, the taste for theatrical performances has spread enormously, and the opportunities of gratifying it have increased in proportion, drama of the first or even a high second-rate quality has perpetually

refused to be written. With rare intervals the works of Shakespeare have kept the stage; but all the other old tragic dramatists have become obsolete, and, except Goldsmith and Sheidan, the old comic writers have shared the same fate. Successive schools of dramatic writing have had their day of favour, sometimes owing to the predilections of certain popular actors. Thus a school imitated from the Germans of the *Sturm und Drang* class was followed by a period of jejune, though decent dramas such as Talfourd's *Ion*, Milman's *Fazio*, and the works of Joanna Baillie and Sheridan Knowles. Then succeeded (though exact succession is rarely to be predicated of such things) a period of light low comedy and farce, such as that identified in one way or other with the names of Mathews, Planché, and Maddison Morton. And this again has been followed by a rage for burlesque, for a new kind of comic opera of not inconsiderable merit, &c. But Shakespeare has always continued to be acted, and has trained actors without producing dramatists. The most considerable, probably, of strictly 19th-century English playwrights was the late Lord Lytton. Yet the *Lady of Lyons*, *Money*, *Richelieu*, &c., though usually effective on the stage, can scarcely be said to be so to the reader, while some later dramas by poets of excellence, though respectable or admirable to the reader, have either not succeeded in being acted at all, or have not been acted successfully.

It has seemed preferable for the plan of such an article as the present to adopt the historical method rather than to divide the drama into its kinds and examine the characteristics of each, such as tragedy, comedy, farce, melodrama, pantomime, and others, with their subdivisions, philosophical and historical. A survey of the great body of dramatic literature in our possession will, however, lead to the not uninteresting conclusion that not merely the forms which literary work for dramatic representation can take, but even the situations and incidents which are suitable to such representation, are by no means very numerous, and tend to reproduce themselves in the practice of different times and different nations with considerable regularity. So also in necessary consequence do the faults incident to the looser and severer systems of drama respectively recur. We also see, as might again be foreseen, that considerably less variety is obtainable in tragedy than in comedy, and that the former is infinitely the more difficult, and, in any excellence, the less abundant variety. Such questions as the baleful effect alleged, and probably with justice, to have been exercised on the drama by the popularity during the 19th century of the prose novel, and the extension of periodical literature generally, can also only be hinted at. But it may be briefly said that the ages and circumstances in which drama has flourished most, have been those in which, by this or that accident, it occupied for a time and sometimes almost monopolised the position of public instructor and informer on questions of thought and news, as well as that of public amuser. And another point worth noting is that the periods of best acting have by no means always coincided with the periods of best drama-writing.

Drama, an inland town of Greek Macedonia, 26 miles NW. of Kavala, is a tobacco-growing centre, with sesame-oil factories, tanneries, and sawmills; pop. 15,000. The department of Drama has an area of 2200 sq. m., and a pop. of 182,600.

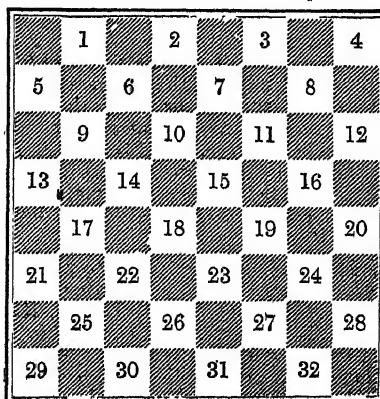

Drammen, a seaport of Norway, on the Dramselv, which here discharges its waters through the Dramsfjord into the Gulf of Christiania, 33 miles SW. of Christiania by rail. The Dramselv, the second largest river in Norway, draining 6500 sq. m., is crossed here by three bridges, one of them 345 yards long. Of the town's three quarters

Bragerhns is north, Strömsö and Tangen south of the river. It manufactures wooden goods and paper pulp, and exports these and timber. Pop. 26,000.

Draper, JOHN WILLIAM, was born at St Helens, near Liverpool, 5th May 1811. He received a course of chemical training in London, and in 1833 emigrated to Virginia. In 1836 he graduated with honours as a doctor of medicine at the university of Pennsylvania; and after holding for some time a professorship in Hampden-Sidney College, Virginia, he was called in 1839 to the chair of Chemistry in the university of New York. He did much to strengthen the medical department of that institution, of which he was for a long time the president. He wrote a large number of papers on scientific subjects, such as the chemical action of light, radiant energy, phosphorescence, spectrum analysis, photography, and the chemistry and physics of living organisms. Among his works are *On the Forces that Produce the Organisation of Plants* (1844), *Scientific Memoirs* (1878), a work on Physiology (1856), *History of the Intellectual Development of Europe* (1862), *History of the American Civil War* (3 vols. 1867-70), and a *History of the Conflict between Science and Religion* (1874). The last-named work had a wide success, and was translated into several languages. He died January 4, 1882.—His son, HENRY (1837-82), attained distinction as an original observer in astronomy and chemistry, working with great enthusiasm and success in both sciences.—Another son, JOHN CHRISTOPHER (1835-85), was a successful teacher of chemistry and physiology, and the author of various text-books and scientific memoirs.

Draught, in maritime affairs, is a technical name for the depth to which a ship sinks in the water when afloat. The draught is marked on the stem or stern-post, or both, from the keel upwards. See SHIPBUILDING.

Draughts, a game played with 'men' on a checkered board, like a chess-board, of sixty-four black and white squares, is of unknown origin. Though Strutt (*Sports and Pastimes*) calls it a modern invention, other authorities consider it very old. It was certainly played in Europe in the 16th century, and in 1668 a treatise on the game was published in Paris by Mallet. The Greeks and Romans had a similar game, and the Egyptians are represented on monuments as engaged in some such amusement. In France it is called *Jeu des Dames*, a name which appears in *Dambrod*, the old Scots name for the draught-board, as also in the German *Damenbrett* and *Damenspiel*.

The figure represents the board, numbered in the usual method for registering games. Two players, each having a set of twelve men—one set white

the other black (or round and square, or distinguished in any other way), sit opposite each other, having their men arranged on squares 1 to 12 and 21 to 32 respectively. The men can be placed either on the black or white squares, but the whole must be placed on one colour only. Whichever colour is used, however, the single corners 4 and 29 must be at the players' left hand.

The object of the game is to clear off the opponent's men altogether from the board, or to so shut them up that they cannot be moved. Generally the black men play first, and as the men are changed each game, the first move becomes alternate. The movements of the men are very simple. Each player alternately moves one man at a time diagonally forward, always keeping on the same-coloured squares. When an enemy's man stands in the way, no move can be made unless there be a vacant square immediately beyond, into which the man can be lifted, in which case the man leaped over is 'taken,' and removed from the board; and so on, till the game is lost and won, or drawn. When a man on either side has succeeded in making his way to the opposite side of the board, he becomes *crowned*, which is done by putting another man on the top of him; and he can then move in any diagonal direction, but always only one square at a time.

When the men are reduced to a few on each side, a somewhat mysterious element called *the move* comes into play. This may be explained by the following case: Suppose only one man left on each side, one on square 2, the other on square 10; should it be the turn of the man on 2 to move, he must obviously be taken and lose the game. The one on 10 is said to have the advantage of *the move*. The only chance for a man with the move against him is to get into a double corner, when the game is drawn. When there are several men left on either side, then it becomes a matter of nice calculation and great importance to find which side has the move, on account of the advantage arising therefrom. Many treatises have been written on the theory of *the move* and the method of calculating it.

James Wyllie ('the herd-laddie') was champion of the world as well as of Scotland till 1894. Other Scottish world champions are Ferrie of Greenock, Jordan of Edinburgh, and Stewart of Blairadam. Famous English players have been Smith, Richmond, Beattie, Gardner, Jewett, Christie, and Binkenshaw; in America (where the game is called *checkers*), Freeman, Barker, and Reed.

A standard book is that by Joshua Sturges (1800), revised by J. A. Kear (1890); another, Andrew Anderson's, especially as re-edited by R. McCulloch (1888). Other writers are 'Berkeley,' Gould, Spayth, Barker, Robertson, Bowen, Hill, and Lees.

Drava, or **DRAVE** (Ger. *Drav*), a river of Europe, rising in Tyrol, at an altitude of 5477 feet, and flowing 447 miles with a general east-south-easterly course, through or along the borders of Carinthia, Slovenia, Croatia, Hungary, and Slavonia, till, 10 miles below Essek, it falls into the Danube. At first it is a mountain-torrent, rushing furiously through Tyrol; but joined by numerous streams, its volume increases, and from Villach downwards (379 miles) it is navigable.

Dravidians is a name given to a large group of the non-Aryan peoples of Southern India, including those speaking Tamil, Telugu, Kanarese, Malayalam, Toda, Gond, and some other tongues of minor importance—in all some 57,500,000 people. These languages are all distinguished by having a rational and an irrational gender in nouns, which in the verbs also are indicated by pronominal suffixes. The grammatical relations are generally expressed by pronominal suffixes. Rask did much

to establish the Dravidian group. See INDIA; Bishop Caldwell's great *Comparative Grammar of the Dravidian Languages* (1856; 2d ed. 1875); Konow in *Linguistic Survey of India* (vol. iv. 1906); Slater, *Dravidian Element in Indian Culture* (1923); and for what ethnologists have called the 'pre-Dravidian' race, see AUSTRALIA (*Aborigines*), ETHNOLOGY, VEDDAS.

Drawback, a term in commerce, employed in connection with the remitting or paying back by government of excise duties on certain classes of articles exported. Excise duties, as a matter of course, enhance by so much the natural price of the commodity on which they are imposed. Were these duties not remitted, the commodity so taxed would not be ordered by those foreign countries where articles of the same kind could be purchased free of such duties. To afford facility for the exportation of these articles, the state resorts to the expedient of returning to the exporter a sum equal in amount to what he or the manufacturer had paid to the excise. Such is drawback. Among other matters of fiscal policy, Adam Smith, in his *Wealth of Nations*, discusses the propriety of giving drawbacks, and sees in them nothing that is adverse to a sound political economy. 'To allow,' he says, 'the merchant to draw back upon exportation, either the whole or a part of whatever excise or inland duty is imposed upon domestic industry, can never occasion the exportation of a greater quantity of goods than what would have been exported had no duty been imposed. Such encouragements do not tend to turn towards any particular employment a greater share of the capital of the country than what would go to that employment of its own accord, but only to hinder the duty from driving away any part of that share to other employments. They tend not to overturn that balance which naturally establishes itself among all the various employments of the society, but to hinder it being overturned by the duty: they tend not to destroy, but to preserve, what it is in most cases advantageous to preserve, the natural division and distribution of labour in the society.' It will, however, be admitted that the system of drawbacks is liable to abuse. The bounties paid by several European states to sugar, for example, were based on the payment of drawbacks, the sum returned being actually larger than the sum paid as duty. See BOUNTY.

Drawbridge. See BRIDGE.

Drawing is the expression of form in graphic art. The term is more particularly applied to expression of form by line. In the preliminary study of drawing, a lead-pencil or other pointed instrument is employed, and the pupil is directed to copy geometrical or other well-defined forms bounded by distinct lines. But in nature no such boundary lines exist; her objects relieve themselves to the eye as spaces that are lighter or darker in tone, or of varying colour. All expression by line of natural things is consequently a conventional rendering, and the true skill of the artist lies in the imagination and insight with which he chooses such lines as are typical and vital, as most simply and forcibly reveal the character of the thing drawn. Such selection is, in particular, the chief excellence of an etched plate, etching being, of all artistic processes, that in which the line is most sensitive and susceptible to the slightest impulse of the artist, and a process in which the line tells by itself, and does not instinctively tend to become merged in a series of accurately gradated tints, as is the case in engraving with the burin. The slightest etchings of Rembrandt are unsurpassable examples of expressive selection of line; while the woodcuts of

Holbein's 'Dance of Death' show how accurately the character of even a minute face may be rendered by a very few blunt lines and touches, set each in its absolutely right place. The more academic method of drawing, of which the classical outlines after Flaxman are examples, has in it less of spirit and insight. It trusts greatly to an unbroken and formally correct outline, and finds its charm less on seizure of individualities of character than on dignity of abstract design, and the grace inherent in flowing curves. In painting, art has rid herself of the conventionalism of line, and, like nature, expresses form by spaces. In speaking of the drawing of a picture, we indicate not only, or chiefly, the contours of its figures, but also their interior modelling, the subtle delicacies of colouring, of tone, and of light and shade, so far as these express the form of objects and reveal their individuality. Architectural drawing has its own rules; and mechanical or engineering drawing differs widely from other kinds in being done wholly by aid of instruments. See ART, PERSPECTIVE.

Drawing and Quartering. The punishment for Treason (q.v.), in force till 1870, was that the offender be *drawn* to the place of execution on a hurdle; that he be hanged by the neck and disembowelled; that his head be severed from his body, and that body be divided into four parts, or *quartered*. Despard (q.v.) and his six confederates were in 1803 drawn, hanged, and beheaded. See *Notes and Queries* for 1880-82.

Drawing-room. See COURT.

Drayton, MICHAEL, poet, was born at Harts-hill, near Atherstone, Warwickshire, in 1563. It is not known whether he was a member of either university; nor is there any foundation for the statement that he served in early manhood as a soldier. In his epistle to Henry Reynolds he refers to the time when he was 'a proper goodly page,' probably in the family of Sir Henry Goodere, his patron. His earliest production was *The Harmony of the Church*, a metrical rendering of scriptural passages. For some reason it gave offence to the authorities, and was condemned to be destroyed. In 1593 he published a volume of eclogues, under the title of *Idea, the Shepherd's Garland*, which afterwards underwent considerable revision. The first of his more important poems was *Mortimeriados* (1596), which he republished (with many alterations) in 1603, under the title of *The Barons' Wars*. As a whole this historical poem is somewhat deficient in interest, but it abounds in fine passages. *England's Heroical Epistles*, first published in 1597, and frequently republished, written on the model of Ovid's *Heroides*, has more polish and less inequality than we find in many of Drayton's works; the versification is fluent and the diction choice. In *Poems, Lyric and Heroic* (c. 1606), appeared the *Ballad of Agincourt*, the most spirited of English martial lyrics. The first eighteen 'songs' or books of Drayton's greatest work, *Polyolbion*, were published in 1613, with annotations by John Selden; twelve more songs were written later, and the complete poem appeared in 1622. This gigantic undertaking was the labour of many years. Drayton aimed at giving 'a chorographical description of all the tracts, rivers, mountains, forests, and other parts of Great Britain'; and expended on his monumental work a vast amount of learning, industry, and skill. From the nature of the subject the poem could not fail to be to some extent monotonous; but the monotony is amply relieved by the beauty of the pastoral descriptions. In 1619 Drayton collected in a single volume all the poems (with the exception of *Polyolbion*) which

he wished to preserve. Eight years afterwards he published a new volume of miscellaneous poems, among which was the whimsical and delightful *Nymphidia, the Court of Fairy*, a triumph of ingenious fancy. His last work, *The Muses' Elysium*, appeared in 1630; it contains some pastoral poems of finished elegance. He died in 1631. There is a monument to him in Westminster Abbey, and the inscription was probably by Ben Jonson. Drayton wrote many sonnets; one of them ('Since there's no help, come let us kiss and part') was pronounced by Rossetti to be 'almost the best in the language, if not quite.' He had a hand in not a few plays, including *Sir John Oldcastle* and perhaps *Henry VI.* Selections have been edited by A. H. Bullen (1883) and Dean Beeching (1899). The 1622 *Polyolbion* and other works have been reprinted by the Spenser Society (1885-92), *Nymphidia*, by Mr Brett-Smith (1921). See Oliver Elton, *Michael Drayton* (1905).

Drayton-in-Hales. See MARKET-DRAYTON.

Dreams have from all times aroused universal interest; they have often decided the destinies of individuals and of nations. The wise man among the ancients was pre-eminently the interpreter of dreams, and the ability to interpret successfully or plausibly was the quickest way to royal favour, as Joseph and Daniel found it to be. Many ideas have been advanced to explain them. The belief was common among the ancients that they were due to the soul's activities, the term soul sometimes being employed in a religious sense, and sometimes as synonymous with mind. Dreams have, in fact, done much to determine human beliefs concerning the nature of the soul and of its continued existence after death. Some thought that the dream was what the soul sees during sleep. The ancients, who deified everything, had a goddess of dreams, Brizo, who was worshipped at Delos. The Greeks and Romans were accustomed to lie down on skins in special places after religious rites and expected definite oracular pronouncements to be conveyed to them in this manner. On the other hand, the *Odyssey* refers to dreams as demons having their home on the road to Hades. Some were said to be shades of departed heroes which had been turned into benevolent or malignant beings. The ancient Hebrews knew that dreams originated inside the head; that hunger and thirst produced dreams in which these desires were satisfied, and that they followed a multitude of cares. Like the heathen they believed that some dreams were divine inspirations, and applied to diviners for their interpretation. Paracelsus (1493-1551) attributed dreams to physical causes, mental causes, astral influences, and spiritual agencies. It was not until the early part of the 19th century that views more in accord with modern teachings appeared. Gray, in his *Theory of Dreams*, in 1808 calls the dream 'the work of the mind, sketches of the fancy, deriving its materials from experience.'

To-day the nature of dreams is beginning to be properly understood. The problem during recent years has been studied with much enthusiasm by Freud and Jung and the psycho-analytical school of thought. These writers have done much to lay bare the psychological mechanism by which the dream is produced, and have placed the study of the dream on a scientific basis. According to Freud, dreams are not meaningless thoughts, but follow definite psychic laws and are replete with information of great psychological importance. He considers that no conscious experience is entirely lost; what seems to have vanished from the current consciousness has really passed into a sub-consciousness, where it lives on in an organised form as real as if it were still part of the conscious personality.

Dreams are the awakening of these dormant complexes, and thus they are transfigured experiences; they are, in fact, a manifestation of ordered mental experience. External stimuli may enter into the complex machinery of dream-formation, but only so far as to stir up some repressed element buried in the dreamer's unconscious mind. The dream as remembered, i.e. its *manifest* content, is merely a condensation of a number of hidden thoughts which represent its *latent* content. The latent content can only be discovered by an exhaustive analysis of the dream as remembered. Such an analysis shows that to effect such a transition from latent to manifest content, a great amount of work must have been performed by the dream; this is termed the *dream-work*.

The dream-work denotes the transference of the dream-thought to the dream-content, and thus it is not creative, it judges nothing, it decides nothing, and it develops no new fancies of its own. It merely prepares the matter for condensation, and, as the result of the other influences, it undergoes displacement and becomes refashioned for dramatisation and explanatory elaboration; thus a speech in a dream is never a new composition, it is merely pieced together out of speeches already made or heard. The words are copied, but the occasion of their utterance is overlooked and their meaning may be violently changed. The dream-work is only the first recognition of a group of psychical processes, to which must be referred the origin of hysterical symptoms, morbid dreams, and obsessions. The more important of the various processes made use of by the dream-work are as follows:

Dramatisation.—The dream has a dramatic character, in which its events unroll themselves before the sleeper, and preserve this character even if the dreamer himself is one of the actors. This dramatic quality is a property of the dream itself, and is due to the necessity in large measure for expression by means of sensory images. Often these images are more vivid than those of waking life. It is just as if a political speech or legal address had to be transformed into pantomime. By far the greater part of the dream consists of definite images of sight and hearing.

Symbolisation.—The relation between the underlying motive of the dream and the form in which this motive is expressed requires a process of symbolisation, the relation being of such a kind that the image of the manifest dream is a concrete symbol of the thought, emotion, or sentiment which forms its latent motive, e.g. motives connected with the dreamer's safety may be represented by a weapon of defence.

Condensation.—This process is one by means of which events which may range from those of the previous day back to the infancy of the dreamer, and thoughts and emotions connected with these events, find expression in the dream by some simple image or group of images. A vast body of experience may thus find expression in perhaps only a single incident of a dream. By this means composite or mixed persons may be built up consisting of one feature of one person and another of another. This character is intimately connected with the question of interpretation. Only when the life-history of the dreamer has been thoroughly investigated from every point of view which can possibly concern the dream is it likely that the correct interpretation is being approached. Any immediate and obvious interpretation of a dream is almost certain to be false or at least incomplete.

Displacement.—Condensation necessarily involves some degree of displacement of interest. If several different thoughts find their expression in a single image, certain interests arising out of one part of the latent content may be represented by an image

with which they seem to have no natural connection. If the dream contains a number of images symbolising different dream-thoughts, the interests attached to one may be transferred to another. Freud attaches special importance to a form of displacement in which an emotional state which forms the most prominent motive of a dream finds expression, not in the form which would seem to be its natural symbol, but in some apparently insignificant image, e.g. a wish of the dreamer himself may find expression in the word or act of some other person. On the other hand, incidents which are really trivial may stand out prominently; the object of these is to hide something which is unpleasant to the dreamer.

Secondary Elaboration.—This term is used to express that part of the dream-work by means of which the manifest dream attains such sense and intelligibility as it may possess, whereby it makes use of interpolations, alterations, distortions, and maskings of unacceptable ideas. A certain amount of elaboration takes place unconsciously (primary elaboration), but secondary elaboration is wholly a matter of early waking thought, and is simply an effort of the dreamer to alter the dream to suit himself. Wishes and phantasies are not infrequently employed in this process, and we may thus be shown directly the true core of the dream, although distorted through admixture with other matter. Dreams differ greatly in their degree of coherence and apparent rationality, due to differences in the extent to which this process of sensory elaboration has been in action.

Disguise and Censorship.—In view of the fact that experiences repressed into the unconscious are mostly of a painful nature, their return to consciousness will again cause pain. The influence of consciousness is thus exerted to prevent their return, and when they attempt to return in the dream, due to the relaxation of conscious inhibition, a psychic conflict takes place, resulting in a compromise; by that they are allowed to enter, but only disguised by symbolisms and other distortions. This mechanism is termed the 'censor.' It is supposed to scrutinise all that comes up from the unconscious, and only allows that to pass which is so distorted that its real nature will not be recognised readily by the dreamer. The function of the censor is protection; it protects the sleeper from being awakened by thoughts which would have this effect if they came up from the unconscious in their real guise. According to this view, the nightmare is due to failure of the censor before the overpowering strength of some emotional stress calling for expression.

Wish-fulfilment.—We pass now from the processes of the dream-work to the nature of the dream-thoughts which thus find expression. Freud considers that every dream expresses the fulfilment of a wish. Many dreams are undoubtedly so. Others express other emotional states, such as anxiety, fear, or shame.

The Role of Sex.—Freud believes that the wishes which provide the motives for the dream, and find their ideal fulfilment in it, arise in the vast majority of cases out of the needs of the sexual life. Emotions and sentiments based on the instinct of self-preservation may also supply motives for the dream.

Dreams may thus be regarded as concealed realisations of repressed desires. They thus do foretell the future, but not the future which will occur, only that which we would like to occur. Dreams may be divided into three classes according to their relation towards the realisation of desire. First, those which exhibit a *non-repressed, non-concealed desire*; these are best seen in children, where the sleeping experience differs very little from the

waking experience, and the dream takes the form of the ungratified desires of the day. Second, dreams which express in *veiled* form some *repressed desire*; these constitute by far the larger number of our dreams, and they require analysis for their understanding. Third, dreams where repression exists, but *without* or with but slight concealment. These dreams are invariably accompanied by a feeling of dread, which brings the dream to an end. This feeling of dread replaces dream-displacement, which in dreams of the second class is prevented by the dream-work. Painful experience depresses the vitality, and thus tends to be repressed, i.e. to disappear from conscious memory. Similarly, distressing dreams, being immediately repressed in the waking state, are not remembered.

In contrast to those who assume that sleep is disturbed by dreams, the function of the dream is to act as the *guardian of sleep*. This is clearly seen in the dreams of children. The bad child who wishes the moon to play with wakes up at night crying for it; the good child remains asleep and dreams he has the moon and is playing with it. The dream which realises his desire is believed during sleep; it thus removes his desire and makes sleep possible. The adult's dream is not so simple, because he has learnt the futility of desire, and thus it is rare for him to have his wishes realised during sleep in the short psychical way. The dream may also prolong sleep by preventing the dreamer being disturbed by external stimuli, e.g. a noise intended to waken the dreamer may be interpreted into the dream in some pleasant form, such as applause, a dinner-bell, or some similar pleasing event, which is fitted naturally into the dream and allows sleep to continue. The dream also may have a protective function, and suspend sleep at the proper time. It acts like a conscientious night-watchman, who first quells the disturbance so as not to awake the citizen, but equally does his duty in awakening the street if he finds the trouble too serious to cope with alone. That the senses aroused during sleep influence the dream is well known, but the stimulus is not properly recognised in the dream, and is intermingled with a number of indefinite interpretations. Thus it is told of Dr Gregory that he dreamt of ascending the crater of Mount Etna after having gone to sleep with a bottle of hot water at his feet. A French observer, Maury, had a series of experiments conducted on himself. When his lips and nose were tickled with a feather he dreamt that the skin of his face was being torn off with a pitch-plaster; pinching the back of his neck made him dream of a doctor who had blistered him there in his infancy.

A striking confirmation of the truth of Freud's interpretation of dreams is found in their resemblance to another aspect of human thought and action, namely, the primitive culture of savage peoples. These two manifestations of the human mind have this much in common, that the mechanism by which dream-thoughts find expression has the same general characters as those which have produced the rites and customs of savage man. Both arise in the unconscious, and the phenomena compared both belong to the realm of mind, the one individual and the other collective. The dream is the expression of the infantile mentality of the individual; savage rites and customs are the expression of the primitive or infantile mentality of the race. The determination of social behaviour by the unconscious is not confined to rude culture, but is only somewhat more obvious in it than among more highly civilised peoples. It may be noted, however, that much the same might be said of the dream as compared with the waking thoughts of the day. We have every reason to believe that our waking thoughts are largely determined by the

unconscious. It is chiefly the greater obviousness of its determination by the unconscious which is characteristic of the dream.

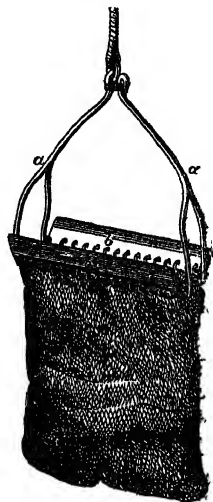

Among barbarous peoples the place occupied by the history and science of the civilised is taken by the myth. The myth is a means of recording knowledge of the unconscious past, and reveals the unconscious history of the race just as the dream does of the individual. They come into being through the action of laws very similar to those which produce the dream.

Certain drugs give a specific character to dreams, e.g. opium, cocaine, cannabis indica, and alcohol, depending on whether the drug is an excitant or a depressant, and on the mentality of the individual. The magnificent visions of the opium-eater have been made familiar by the classical account of De Quincey.

LITERATURE.—Freud, *The Interpretation of Dreams* (1913), *On Dreams* (1914); Bergson, *Dreams* (1914); Rivers, *Dreams and Primitive Culture* (1917); Jung, *Analytical Psychology* (1917); Walsh, *The Psychology of Dreams* (1920).

Dredge, a machine used for bringing up from the bottom of lakes, or of the sea, specimens of the organisms and plants which exist there. A rude species of hand dredge appears to have been in use from the earliest times, and is still employed among the peoples of the Pacific islands, an improved form being common in all civilised countries possessing a seaboard. As a means of scientific investigation the dredge was first used by Müller, who, before 1779, had made systematic investigations into the deep-sea fauna and flora off the coasts of Norway and Denmark. Other naturalists were not slow to recognise the value of the results thus obtained, and the dredge was extensively employed by the principal scientific men of the period, among whom Forbes especially deserves mention, although it was some time before its full value was known.

For ordinary purposes, and for use where the water does not exceed 100 fathoms in depth, Dr Robert Ball's dredge (1838) is generally recognised as most useful. With slight modifications, it continues to be employed in preference to other forms. The frame is 1½ feet long, with scrapers not more than 3 inches wide, and so placed that the distance across the scraping surfaces is between 7 and 8 inches; these scrapers are connected by the frame-ends, made of bar iron five-eighths of an inch in diameter. Two curved iron arms (a, a in fig.) are fixed to the extremities of the cross-bar by means of 'eyes,' which allow the arms to fall down over the mouth of the dredge. The bag is secured to the thick inner end of the scrapers by means of an iron rod and stout iron rings (b, b in fig.). This bag may be of any depth, but 2 feet will be found very convenient; it ought to be hand-netted from stout twine, and the lower end lined with coarse canvas, to prevent the escape of the more minute animals and plants. All the materials used in the construction of a dredge, the iron especially, ought to be of the very best quality. Captain Calver, of the *Porcupine* (1869-70), invented the use of hemp tangles (half-a-dozen fastened to an iron rod attached to the bottom of the dredge, or behind

Dr Ball's Dredge.

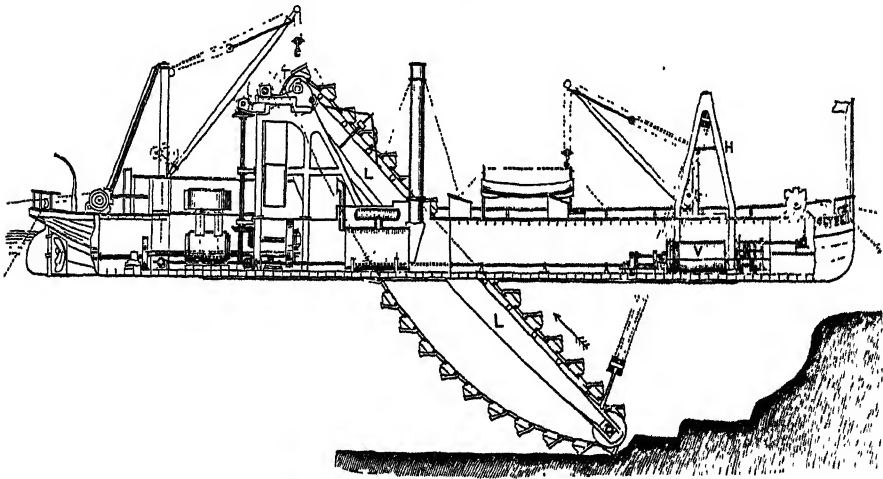

it), and found them very successful in sweeping the bottom of objects which did not find their way into the dredge.

In the cruises of the *Blake* (1877-80), a case of stout canvas was used to cover the dredge, with the result that the most delicate organisms were brought up entirely uninjured, even after the machine had been dragged along rough ground for some time; the cover was also found to preserve the net from injury by contact with sharp rocks. In dredging, before the net is let down, the depth of the water should always be ascertained by casts of the lead, when not already approximately known, and, whenever practicable, a deep-sea thermometer ought to be used in conjunction with the lead, and the temperature of the water, which has a more important bearing on the distribution of life than is generally supposed, carefully observed and recorded. The rope attaching the dredge to the vessel ought to be tested before use, as any failure in it may lead to the loss of the dredge and its contents, and must be kept sufficiently slack to prevent its snapping from any sudden jerk. The length let out should be, as a rule, double the

depth of water, to avoid danger of breakage from ordinary causes. If, however, the water be under 30 fathoms, the length of rope ought to be three times the depth. The boat from which dredging operations are carried on should always be kept moving, but very slowly. Wire-rope is used for deep-sea work with large vessels.

Dredger, a machine for clearing out or deepening harbours, canals, river channels, &c. Sometimes a channel can be deepened by natural scour assisted perhaps by training-walls, but when a large quantity of hard material has to be removed, dredging has often to be adopted. The material is pumped up or raised by buckets or grabs, discharged into barges, and removed to the place of deposit. The cost of dredging is very variable, and prior to 1914 might work out at from 1½d. to 1s. 6d. per ton; the larger sum might occur in the case of small quantities and with hired plant and when the place of deposit was some distance away. Repairs and maintenance expenses form a heavy item in the cost of dredging operations.

There are many types of dredger suitable for different circumstances—bucket-ladder dredgers,

Dredger.

grab, suction, rock-breaking, and eroding dredgers, of which the first-named is the most common. As shown in the diagram, the upper tumbler, T, is made to rotate by powerful gearing worked by the engines, and this gives motion to the chain to which the buckets are attached. The bucket-ladder, L, is raised and lowered by the topping-lift, H, and the lower end can project before the bow, and so cut a passage for the vessel through a dry bank.

A bucket-dredger at work must be securely moored by bow and stern chains or steel wire-ropes run out from each bow and quarter. The system of cross-dredging is generally adopted. The vessel is moored at one side of the bank to be dredged, the ladder is lowered so as to take a cut, and the one set of side-chains are hove in and the opposite set paid out. When the bank has been crossed, the bow-chain is hove in perhaps 12 feet, and a new cut is carried across, and so on till the required depth is reached. By means of shoots the dredgings are discharged into barges lying alongside. When these are filled they steam to the place of deposit—usually in deep water or out at sea—and the stuff is discharged by opening the hopper-doors in the bottom of the vessels. The barge-loading dredger works expeditiously, as it dredges and fills barges continuously; in the case of the hopper-dredger, which dispenses with barges, the dredging

is entirely suspended while steaming away to the place of deposit, and time is also lost in dropping and picking up moorings, particularly in stormy weather. But each system has its advantage according to circumstances.

A bucket-ladder dredger, built in 1914 for deepening the Clyde below Port Glasgow, was 157 feet long, 34 feet beam, and 11 feet deep. In ordinary dredging material it could lift 500 tons per hour from a depth not exceeding 42 feet. Two sets of buckets were supplied, the one for hard boulder clay with buckets of 7 cubic feet capacity each, and the other for softer clay and sand with buckets of 18 cubic feet capacity. The vessel was self-propelling, and cost £21,000, but bucket-dredgers are made of much larger size and power than this vessel. Two hopper-barges, costing £15,000 each, were required to carry the dredged material some 12 miles away. These barges conveyed 1200 tons of material, and steamed, when loaded, at about 10 knots.

Grab-dredgers are used chiefly in soft material, and consist of a bucket suspended from the end of an arm. The bucket, by its weight, is forced into the material, and is opened and closed by a special arrangement of chains. The system of suction-dredging is also largely adopted in dredging soft material. A long pipe, fitted with a nozzle, is inserted into the sand, which is pumped up and

discharged either into barges or on to the shore through long pipes. Rock-dredging operations are the most expensive. When soft rock has to be removed, this may be done by claws attached to the buckets of a powerful dredger. If the rock is too hard for this method, it may be broken up either by blasting or by heavy rams—in principle huge chisel-pointed hammers weighing several tons each—and afterwards removed by grab or by buckets. The eroding-dredger is the simplest form of dredging-machine. By its means the material is loosened and left to be transported elsewhere by the current. Dredgers, combining several types, are frequently constructed.

Dred Scott Case, brought before the supreme court of the United States in 1856, was the case of a negro called Dred Scott, who with his wife and two children had been held as slaves by a Dr Emerson in Missouri. On returning thither, Scott and his family claimed to be free, as having resided with their owner in Illinois and Minnesota. The decision was hostile to their claim, and they were held to be still slaves. See **SLAVERY**.

Dreissena, a genus of bivalves, in the mussel family (Mytilidae), peculiar in having the mantle halves almost completely united. One species (*D. polymorpha*) deserves notice, since, from its home in the Black Sea and Caspian, it has travelled westward on ships or logs, and has now established itself in many European (including British) estuaries and canals.

Drelincourt, CHARLES, a French Protestant divine, was born at Sedan in 1595, and was from 1620 a pastor near Paris, where he died in 1669. He wrote, among other works, a book that was translated and frequently reprinted in English, under the title *Consolations against the Fear of Death*. See **DEFOE**.

Drenthe, a frontier province of the Netherlands, bordering on Hanover; area, 1030 sq. m.; population, 210,000. It is the least populous province in the kingdom. The soil is in general poor, only about one-half of the surface being capable of cultivation, the remaining portion covered chiefly with heath and moass. The inhabitants are chiefly employed in agriculture, pasturage, and in digging and exporting peat.

Drepanum. See **TRAPANI**.

Dresden, the capital of the republic of Saxony, is situated in a charming valley on the Elbe, 116 miles SE. of Berlin, and 62 ESE. of Leipzig. The Altstadt and Friedrichstadt on the left bank of the Elbe, and the Neustadt and Antonstadt on the right or northern bank, are united by several bridges, including the Augustus Bridge, rebuilt 1906; the Albert Bridge, erected in 1875-77, a masterpiece of architecture; and the Marienbrücke, which is at once a railway and a carriage bridge. Dresden is a pleasant and attractive, though not exactly a beautiful town. It contains several open squares, and is embellished with statues and public gardens; and the Brühl Terrace, on the south bank of the Elbe, originally laid out by Count Brühl in 1738, is a charming promenade, on which in 1889 extensive improvements were made. Its architecture and splendid art collections, and its artistic and educational reputation, render Dresden one of the pleasantest and gayest of the smaller residential continental towns.

Dresden occupies an important position in the history of art, especially as the cradle of rococo art, which culminated here about the middle of the 18th century. Herder called it the German Florence. The Academy of Art, opened in 1764, and specially famous for drawing and architecture, the choir in connection with the Roman Catholic church, and the Conservatory of Music, are all of

no small importance to the progress of art at the present day. Scientific, educational, æsthetic, and benevolent institutions also abound in the town. The museum, one of the finest specimens of modern architecture, built by Semper in 1847-54, contains collections of engravings (400,000 examples) and drawings, besides the famous picture-gallery. The last, which owes its origin chiefly to Augustus III. of Saxony, who purchased the Modena gallery in 1745, is one of the finest collections out of Italy, and contains about 2400 paintings, mainly by Italian and Flemish masters. The gem of the collection is the 'Sistine Madonna,' by Raphael (see **PIACENZA**); other masterpieces being Titian's 'Tribute Money,' and Correggio's 'Magdalene,' and 'La Notte.' The so-called 'Holbein Madonna,' often ranked second among the treasures of the gallery, is now admitted to be a replica, the original being at Darmstadt. Adjoining the museum is the Zwinger, a remarkable rococo building of 1711-22, designed as the vestibule of an elaborate palace, of which, however, no more was ever built. It now contains valuable collections of casts, zoology, mineralogy, and mathematical and philosophical instruments. The Johanneum, erected as royal stables at the end of the 16th century, now accommodates the historical museum, founded in 1833, the gallery of arms, and the priceless collection of porcelain, which embraces 15,000 specimens. The Augusteum, or collection of antiquities, chiefly Roman objects of the Imperial times, and the Public Library, are deposited in the Japanese Palace, built in 1715 in the Neustadt. The library contains over 400,000 volumes, 20,000 maps, and 4000 MSS., and is particularly complete in the departments of literary history and classical antiquity, as well as in histories of France and Germany. The 'Green Vault' in the royal palace contains a valuable collection of precious stones, pearls, and curios, and articles in gold, silver, ivory, &c. The cabinet of coins is also preserved in the palace. The list of art treasures in Dresden may be closed with the collection of antiques (chiefly ecclesiastical), and the gallery of casts of the works of the sculptor Rietschel, both in the 'Lustschloss,' erected in 1680, in the Grosse Garten, a handsome public park, 350 acres in extent. Among the important buildings not yet mentioned are the royal palace, a large edifice, begun by Duke George in 1534, completed in 1890-1902; the prince's palace, erected by Augustus II. in 1718; the Brühl Palace, now the Ständehaus; and the magnificent new theatre (1871-78), designed by Semper. Of the churches, the finest are the Frauenkirche (1726-34), with a lofty dome and lantern 320 feet in height; the Roman Catholic church (1737-56), in an elaborate baroque style, adorned on the exterior with sixty-four statues; the Sophienkirche (1351-57), restored and provided with towers in 1865-69; and the Kreuzkirche, the largest church in Dresden, rebuilt 1764-85, and again after being burnt down in 1897. The Synagogue (1838-40), by Semper, is worthy of mention. There is a technical high school.

The most important industries are the manufactures of gold and silver articles, artificial flowers, machinery, chemicals, paper-hangings, painters' canvas and colours, chocolate, glass, pianofortes, photographic apparatus, cigarettes, straw-plaiting, brewing, and market-gardening. The so-called 'Dresden china' is manufactured not at Dresden but at Meissen (see **POTTERY**). A considerable trade is carried on by means of the Elbe, which is also enlivened by numerous small passenger-steamers. Pop. (1871) 177,087; (1885) 246,086; (1890) 289,844; (1910) 548,308; (1919) 587,748.

The oldest part of the town (originally Slavonic) was on the right bank of the river, but having been

rebuilt after a fire in 1685, it has since been known as the Neustadt. Henry the Illustrious made Dresden his capital in 1270, and after the division of the Saxon lands in 1485 it became the seat of the Albertine line, and its prosperity increased. Several sovereigns contributed to its embellishment, as Augustus I. and Augustus II. It suffered severely, however, during the Seven Years' War, and again in August 1813, when the armies of the allies gathered from all sides towards Dresden. The assault was made on the 26th, but was beaten back by Napoleon; and the allies retreated. Napoleon did not quit the city till the 7th Oct., leaving nearly 30,000 men behind. As all access was cut off by the Russians, the city suffered from famine, and capitulated on 11th Nov. The revolution of 1849 also did great damage to the town. Dresden was occupied by the Prussians in 1866. Since that period great and numerous improvements have been effected, and the city has been extended, especially in the south-eastern suburbs, known as the English and American quarters.

Dress. See FASHION.

Dreux, a town of France, in the dep. of Eure-et-Loir, on the Blaise, 27 miles NNW. of Chartres by rail. It lies at the foot of a hill crowned with the ruins of the castle of the Counts of Dreux. From among the ruins rises a beautiful chapel, erected by the mother of Louis-Philippe in 1816, to which were removed in 1876 the remains of the king and others of the Orleans line who had died in exile. The town-hall and the parish church are both good specimens of Gothic. Pop. 11,000. Dreux is the ancient *Durocassis*. In 1562 the Constable Montmorency defeated the Huguenots here.

Drew, SAMUEL (1765-1835), the 'Cornish metaphysician,' was born at St Austell, and had been a smuggler and shoemaker when in 1788 he became a Wesleyan preacher. He died at Helston.

Dreyfus, ALFRED, born in 1854 at Mulhausen in Alsace, the son of a rich Jewish manufacturer, migrated in 1874 to Paris. He was an artillery captain, attached to the General Army Staff, when in 1893-94, charged with delivering to a foreign government documents connected with the national defence, he was court-martialled, degraded, and transported to the Cayenne Île du Diable. The efforts of his wife and friends to prove him an innocent victim of malice, injustice, and forgery plunged France into a chaos of militarism and anti-Semitism. He was brought back to France in 1899, retried at Rennes, reconvicted 9th September, sentenced to ten years' imprisonment, but immediately pardoned. The proceedings against him were finally quashed in July 1906, and he was reinstated in the army as major. He was given the Legion of Honour in 1919. See the article ZOLA.

Dreyse, JOHANN NIKOLAUS VON (1787-1867), born near Erfurt, worked as a locksmith in Germany, and in a musket-factory in Paris 1809-14. He then founded an ironware factory in Sommerda, and commenced the manufacture of percussion-caps under a patent in 1824. In 1827 he invented a muzzle-loading, and in 1836 a breech-loading needle-gun, which was adopted in the Prussian army in 1840. In 1864 Dreyse was ennobled.

Briesch, HANS, physiologist, and professor of Philosophy at Heidelberg (1911), was born at Krenzach in 1867. His works on the organism, vitalism, individuality, &c. have been translated.

Driffield, GREAT, the chief town in the Wolds, East Riding of Yorkshire, 11 miles N. of Beverley by rail, is connected with Hull, 10 miles to the south, by a navigable canal. The surrounding district is fertile, and the town has a considerable corn and cattle trade, besides manufactures of flour, linseed-cake, and artificial manures. Pop. 5700.

Drift, a name formerly given to boulder-clay, a deposit of the Pleistocene epoch. More fully, it was called the Northern Drift, Glacial Drift, or Diluvial Drift, in allusion to its supposed origin. The old river-gravels of Pleistocene age were also often termed river-drift. The term drift has now fallen out of use. For an account of the deposits formerly termed drift, see BOULDER-CLAY, PLEISTOCENE SYSTEM. For the drift-men, see MAN.

DRIFT-WOOD is wood carried by tides and currents to a distance from its native locality. Thus the shores of the Farø Islands, Iceland, &c. are often strewn with logs brought by the Gulf Stream. Fragments of drift-wood occur as fossils in many geological formations, as in the Carboniferous Sandstones, the Chalk, the London Clay, &c.

SAND-DRIFT is sand driven and accumulated by the wind. Deposits thus formed are occasionally found among the stratified rocks, but compared with other strata they are few, though, from their anomalous character, an acquaintance with their phenomena is of importance to the geologist. As a rule, the mineral ingredients of wind-blown sand are better rounded than the grains of an aqueous accumulation of sand—the latter being carried in suspension, and thus to a large extent escaping the mutual trituration to which the former are subjected. Moving sands are at the present day, in many places, altering the surface of the land. In the interior of great dry continents, as Africa, Asia, and Australia, extensive districts are covered with moving sands. The continuous blowing of a steady wind in one direction often covers a rich tract with this arid material. But the influence of the wind on loose sand is most evident along low sandy coasts, where hills, called 'dunes,' are formed entirely of it; they sometimes attain a considerable height, as much, for instance, as 200 or 300 feet. Dunes (q.v.) are advancing on the French coast of the Bay of Biscay at the rate of about 60 feet per annum, covering houses and farms in their progress. Similar accumulations are forming on the coasts of Elgin, Cornwall, Wexford, and other parts

Section of Culbin Sandhills.

of the British Isles. The Culbin Sands, in Elgin and Nairn shires, cover a large district which at a period not very distant was rich arable land. The prevailing wind is from the west, hence the hills are slowly moving in an easterly direction, at the rate of a mile in somewhat less than a hundred years. A singular stratification exists in these hills. The prevailing west wind lifts, or rather rolls the particles of sand up the gentle incline of the western aspect of the hill, until they reach the summit, where they fall, forming a steep declivity to the east, equal to the angle of repose for sand. A shower consolidates the surface of the new bed, or a land-breeze carrying fine dust separates it by a very thin layer of finer material from the one that follows, and thus, as the hill moves eastward, a regular series of strata is formed at a high angle, as is shown by the diagram. The progress of the hill is represented by the dotted outline. Little can be done to arrest the progress of these devastating sand-drifts. It has been recommended to plant *Carex arenaria* and similar sand-loving plants, which have long creeping roots: they certainly check to a considerable extent the influence of the wind. A great forest of sea-pine seven miles in width has since 1789 been maintained along the

sand-dunes of the French *Landes* (q.v.), with great benefit to the country inland.

Drill (*Cynocephalus leucophaeus*), a species of Baboon (q.v.), a native of Guinea, similar to the mandrill, but rather smaller and less ferocious.

Drill is a general name for the exercises by which soldiers and sailors are made efficient. In the army, there are three classes of drill. First, 'setting-up' and 'gymnastic' drill, to improve the physical development of the recruit; secondly, sword, lance, and bayonet exercises, gun-drill, riding, driving, stretch, shelter-trench, and repository drill (the technical name for shifting heavy ordnance), &c., to teach him to handle his arms, horse, or tools to the best advantage; thirdly, marching, squad, company, squadron, battery, battalion and brigade drill, &c., to enable the men composing these various bodies to act together. After some weeks of such drill, there are added tactical exercises, such as signalling, outposts, skirmishing, which complete the instruction of the recruit. An ordinary recruit requires about four months' drill to become efficient in the infantry, two years' in the cavalry, and three in the artillery. In the navy, the drills vary in the same way with the nature of the duties required.

Drills. See BORING

Drims. See WINTER'S BARK.

Drinking Usages. See TOASTS.

Drinkwater, JOHN, born in 1882, worked in insurance offices, and from 1903 published reflective poems (*Swords and Ploughshares*, *Olton Pools*, *Tides*, *Loyalties*, *Seeds of Time*, *Preludes*), studies of William Morris and Swinburne, and plays in verse and prose, *Abraham Lincoln* (1918), a sort of chronicle play, proving a great success on the stage. *Mary Stuart*, *Oliver Cromwell*, *Robert E. Lee*, were later achievements in this refractory kind. He was one of the promoters of the Birmingham Repertory Theatre.

Dripstone, a projecting moulding or tablet placed over the head of a Gothic doorway or window, originally to throw off the water (whence it is also known as a water-table or weather-moulding), latterly as an ornamental appendage, serving to enrich and define the outline of the arch, and applied internally as well as externally. Ruskin points out that the dripstone is one of the chief features which distinguish the style of the rainy north from that of the more sunny south.

Driving (see COACHING, and RIDING AND DRIVING). Driving vehicles or riding furiously and recklessly in a public place, to the danger of the lieges, is an offence at common law in England, and may be prosecuted as culpable neglect of duty according to the law of Scotland. It has, however, been made a statutory offence, and many acts have been passed under which prosecutions are now as a rule brought. In the United States, furious driving in cities generally is a misdemeanour punishable by fine and imprisonment. In the absence of State laws, municipalities regulate the rate of driving.

Drogheda, a seaport, and, till 1898, county of itself, in the south-east of County Louth, built mostly on the north bank of the river Boyne, 4 miles from its mouth, 32 N. of Dublin by rail, and 81 S. of Belfast. The Boyne is crossed here by a railway viaduct 95 feet high. There are linen and cotton manufactures, ironworks, tanneries, breweries, and salt-works. It has a considerable export trade, chiefly with Liverpool (140 miles distant), in corn, meal, flour, cattle, linen, hides, butter, and eggs. Vessels of 500 tons reach the quay, and barges of 50 tons ply 19 miles up the Boyne to Navan. Pop. (1851) 16,845; (1891) 11,873;

(1911—as extended in 1896) 12,425. Up to 1885 Drogheda sent one member to parliament. From the 14th to the 17th century, Drogheda (often called *Tredah*) was the chief military station in Leinster. Poyning's laws were enacted here in 1494, and about the same time a mint was set up. In 1649 Cromwell stormed the town after a desperate struggle, and for a stern lesson to the Irish put its stubborn garrison to the sword. Drogheda surrendered to William III. the day after the battle of the Boyne (q.v.).

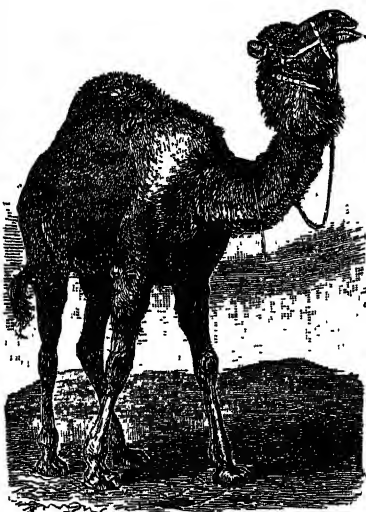

Drohobycz, a town of Poland, in Eastern Galicia, 50 miles SW. of Lemberg by rail. It has extensive salt-works, petroleum-works, and dye-works. Pop. 27,000, half of whom are Jews.

Droits, ADMIRALTY. See ADMIRALTY DROITS.

Droitwich, a municipal borough in Worcestershire, on the Salwarpe, 6 miles NNE. of Worcester. It is a railway junction, and is connected by canal with the Severn. Originally a British town, and probably the Roman *Salinæ*, it was first known as Wych, from the salt-springs, to which Droit was afterwards prefixed, expressing a legal right to them. Its salt trade has been famous from remote times. Pop. 4600. Droitwich sent one member to parliament until 1885. The admirably equipped saline baths are visited by thousands.

Drôme, a department of France, on the east bank of the Rhone, to the south of the department of Isère. Area, 2508 sq. m. Pop. (1866) 324,231; (1921) 263,509. The surface is generally hilly, and even mountainous in the east, where spurs of the Alps rise to a height of 5900 feet; and, except in the Rhone valley, the soil is not very productive. Drôme is traversed by a number of affluents of the Rhone, the most notable being the Isère and the Drôme (75 miles), from which the department takes its name. Along the Rhone, however, where a Mediterranean climate prevails, the almond and olive flourish, though an occasional crop is lost from frost, and oil-nuts and the mulberry are extensively grown. Also, the cultivation of the vine was an important industry before the ravages of the Phylloxera affected it; Hermitage and the white wine Clairette de Die were especially famous. Wheat, potatoes, and melons are produced in large quantities, and the cultivation of truffles has become noteworthy.

Coal, cement, and potter's clay are found; and there are manufactures of silk, woollen, straw, and iron goods, pottery, paper, leather, and glass, besides an active trade in the raw products of the district. The department is divided into the four arrondissements of Valence, Montélimar, Die, and Nyons, with the town of Valence for capital.

Dromedary.

Bromedary, a swift variety of the one-humped camel (*Camelus dromedarius*), bearing the same relation to it as race-horse to cart-horse. Its usual

pace is a trot, which, with terrible joltings to the rider, can be maintained often at the rate of nine miles an hour for many hours on a stretch. A journey of 600 miles can be performed at a slower rate in five days. After running for twenty-four hours, when in good condition, the dromedary is refreshed with a frugal meal of barley and powdered dates, along with a little water or camel's milk, and is then ready for another day of it. A gallop is a pace for which the dromedary is not adapted. Many varieties—e.g. for racing—are reared, and white forms are much prized in some parts of the East. Though now distinctive of North Africa, the dromedary seems to have been unknown to the ancient Egyptians. For general information, see CAMEL.

Dromore, a town, with linen manufactures, in the north-west of County Down, on the Lagan, 17 miles SW. of Belfast by rail. Pop. 2400. It is still the seat of a Roman Catholic diocese, as it was also of an Episcopal till 1842, when it was united with Down. Jeremy Taylor and Thomas Percy were bishops of Dromore.

Drone. See BEE.

Drontheim. See TRONDHEIM.

Dropsy (Gr. *hydrōps*, from *hydōr*, 'water'), a class of diseases always of serious import, though not often, perhaps, directly fatal. Dropsy is rather a symptom than a disease; it consists of the effusion of watery fluid from the blood into the skin and subjacent textures, or into the cavities of the body. When the effusion is chiefly in the superficial parts, the dropsy is called Anasarca (*ana*, 'upon,' *sarx*, 'the flesh'); when it is in the abdomen, it is termed Ascites; when in the space around the lungs, Hydrothorax. Dropsy most commonly depends on disease of the Heart (q.v.) or Kidneys (q.v.); in cases of ascites, the liver and spleen are often at fault. The treatment of dropsy is chiefly by Diuretics (q.v.) and other evacuant remedies, which remove the fluid from the textures by unloading the blood of its excess of serum. In other cases, where the power of the heart is at fault, cardiac stimulants are given. In all cases, the internal organs should be, if possible, submitted to a strict medical examination, and the treatment regulated accordingly. Mechanical means are also frequently used to relieve the patient of the fluid—in the case of the cavities of the body, Tapping (q.v.); in the cellular tissue either free incisions, or small tubes inserted through the skin, by which the fluid is allowed gradually to drain away.

Dropwort. See SPIRÆA, and WATER DROPWORT.

Droseraceæ, a small order of archichlamydeous dicotyledons allied to Saxifragæ, and including about 100 species. They are small herbaceous plants, generally inhabiting marshy places, with leaves frequently circinate in bud, and usually covered with glandular processes or hairs. These are very frequently adapted to the capture and digestion of insects. See INSECTIVOROUS PLANTS.

Drosky. See CARRIAGE.

Drosophila. See FRUIT-FLY.

Drouet, JEAN BAPTISTE, COMTE D'ERLON, French marshal, was born 29th July 1765, at Rheims, entered a regiment of volunteers in 1792, and took part during the years 1793-96 in the campaigns of the Moselle, Meuse, and Sambre. His conduct in the Peninsular war was highly distinguished. After the fall of Napoleon, the Bourbons gave him the command of the 16th division, but he was shortly after arrested on the charge of conspiring against the royal family. On the return of Napoleon from Elba, he contrived to seize the citadel of Lille, in which he had been imprisoned,

and held it for the emperor, who made him a peer of France. At the battle of Waterloo he commanded the first *corps d'armée*. After the capitulation of Paris, he fled to Bavaria, where he resided until the July revolution, when he returned to France, and received in 1832 the command of the army of Vendée. During 1834-35, he held the important office of governor-general of Algeria, and in 1843 was elevated to the rank of marshal. Drouet died 25th January 1844.—JEAN BAPTISTE DROUET (1763-1824) was a zealous revolutionist of the extreme Jacobin section; and LOUIS DROUET (1792-1873) was a very famous flute-player.

Drouyn de Lhuys, ÉDOUARD, a French statesman, born in 1805, was attached to the embassies at Madrid and at the Hague. In 1840 he was placed at the head of the commercial department under the Minister of Foreign Affairs, and shortly after was elected deputy for Melun; but he afterwards was deprived of his office because of his opposition to the government. Under Louis Napoleon's presidency he became Minister of Foreign Affairs, and in 1849 went to London for a short time as ambassador; after the *coup d'état* he became one of the vice-presidents of the Imperial Senate, and again Minister of Foreign Affairs. Being disappointed at the issue of the Vienna Conferences in 1855, he resigned his office. In 1863 he was recalled to his old post, resigning again in 1866. He died March 1, 1881.

Drowning. See ASPHYXIA, RESPIRATION (ARTIFICIAL), and HUMANE SOCIETY.

Drowning was long a customary mode of capital punishment. Tacitus, writing about the end of the 1st century, tells us that the Germans hanged their greater criminals, but that meaner and more infamous offenders were plunged under hurdles into bogs and fens. Drowning was also a Roman punishment. The Lex Cornelia decreed that parricides should be sewn up in a sack with a dog, cock, viper, and ape, and thrown into the sea. The Anglo-Saxon codes ordered women convicted of theft to be drowned. The punishment was in such common use throughout the middle ages that grants of capital jurisdiction ran *cum fossa et furca* (i.e. 'with pit and gallows'). The pit, ditch, or well was for drowning women; but the punishment was occasionally inflicted on men. In Scotland, in 1556, a man convicted of theft and sacrilege was sentenced to be drowned, 'by the queen's special grace.' So lately as 1611 a man was drowned at Edinburgh for stealing a lamb; in 1623 eleven Gypsy women were sentenced to be drowned in the Nor' Loch there. By that time the punishment of drowning had become obsolete in England. It survived in Scotland until 1685 (the year of the drowning of the Wigtown martyrs), and in France was employed so late as 1793 at Nantes in the infamous *noyades* of Carrier (q.v.). The offending wives of the Turkish sultans were wont to be sewn up in a sack and cast into the Bosphorus.

Droylsden, Lancashire, a suburb of Manchester, 3½ miles E. of it, with railway station. Pop. 14,000.

Droz, ANTOINE GUSTAVE, novelist, was born at Paris, 6th June 1832, grandson of Jean Pierre Droz (1746-1823), an engraver of medals, well known in his day. At first Droz studied art, but soon to his profit exchanged the pencil for the pen, making a brilliant reputation that is not quite easy to understand in the pages of *La Vie Parisienne*, with his *Monsieur, Madame, et Bébé*, which, published in book-form in 1866, reached in twenty years its 120th edition. Later books are *Entre Nous* (1867), *Le Cahier bleu de Mademoiselle Cibot* (1868), *Autour d'une Source* (1869), *Un Paquet de Lettres* (1870),

Les Étangs (1876), *Tristesses et Sourires* (1883), and *L'Enfant* (1885). He died 22d October 1895.

Drugget (Fr. *droguet*), a woven and felted coarse woollen fabric, usually with a printed pattern, chiefly used for covering carpets, and hence called in some parts of Great Britain crumb-cloth. It is generally too thin to take the place of a proper carpet, but it is sometimes so employed. The name is also given to a stout dress fabric made with a linen warp and a worsted weft. It is made into petticoats, workmen's aprons, &c.; sometimes only the weft, but often both warp and weft, being dyed.

Drugs. See ADULTERATION, CHEMISTS AND DRUGGISTS, PHARMACOPOEIA, PHARMACY, and PRESCRIPTION; also such articles as ARSENIC, MORPHINE, OPIUM.

Druidism is commonly spoken of as the religious system of the Gauls and Britons, or of the Celtic peoples. Sir John Rhys, however, held that the real religion of the Celts was an Aryan Polytheism like that of Italians and Greeks; and that Druidism, in so far as found amongst the Celts of Gaul or Britain, was by them derived probably from pre-Celtic and non-Aryan aborigines (Ivernians, Iberians, Euskarians or Basques, Neolithic men?), and was thus non-Aryan in origin. There is no reason, he says, for holding that Druidism was found amongst the Brythonic races proper, though it was in force amongst the Goidelic (Gaelic) peoples of the British Isles. Cæsar thus describes the character and functions of the Druids: 'They attend to divine worship, perform public and private sacrifices, and expound matters of religion. A great number of youths are gathered round them for the sake of education, and they enjoy the highest honour in that nation; for nearly all public and private quarrels come under their jurisdiction; and when any crime has been committed, when a murder has been perpetrated, when a controversy arises about a legacy or about landmarks, they are the judges too. They fix rewards and punishments; and should any one, whether a private individual or a public man, disobey their decrees, then they exclude him from the sacrifices. This is with them the severest punishment. The persons who are thus laid under interdiction are regarded as impious and wicked people; everybody recoils from them, and shuns their society and conversation, lest he should be injured by associating with them. They cannot obtain legal redress when they ask for it, nor are they admitted to any honourable office. All these Druids have one chief, who enjoys the highest authority amongst them. When he dies, he is succeeded by the member of the order who is most prominent amongst the others, if there be any such single individual; if, however, there are several men equally distinguished, the successor is elected by the Druids. Sometimes they even go to war about this supremacy. At a certain time of the year, the Druids assemble on the territory of the Carnutes, which is believed to be the centre of all Gaul, in a sacred place. To that spot are gathered from everywhere all persons that have quarrels, and they abide by their judgments and decrees. It is believed that this institution was founded in Britannia, and thence transplanted into Gaul. Even nowadays, those who wish to become more intimately acquainted with the institution generally go to Britannia for instruction's sake.

The Druids take no part in warfare; nor do they pay taxes like the rest of the people; they are exempt from military service, and from all public burdens. Attracted by such rewards, many come to be instructed by their own choice, while others are sent by their parents. They are reported to learn in the school a great number of verses, so that

some remain there twenty years. They think it an unhallowed thing to commit their lore to writing, though in the other public and private affairs of life they frequently make use of the Greek alphabet. . . . Beyond all things, they are desirous to inspire a belief that men's souls do not perish, but transmigrate after death from one individual to another; and they hold that people are thereby most strongly urged to bravery, as the fear of death is thus destroyed. Besides, they hold a great many discourses about the stars and their motion, about the size of the world and of various countries, about the nature of things, about the power and might of the immortal gods; and they instruct the youths in these subjects.'

It is easy to comprehend that this powerful priesthood did all it could to uphold the national cause against the Roman conquerors, and urged the people to rebellion; so much so, that the Emperor Claudius found it necessary to interdict formally the practising of Druidical rites, which seem, however, to have continued down to the extinction of paganism. Besides being priests and teachers of religion, the Druids appear also to have been adepts in the magic arts, and were versed in the mysterious powers of animals and plants. The oak-tree was especially sacred among the Druids. In oak-groves they frequently performed their rites, and many have even derived their name from this custom. They also had a special reverence for the mistletoe, when growing on an oak. According to Pliny, a Druid, clothed in white, mounted the tree, and with a knife of gold, cut the mistletoe, which was received by another, standing on the ground, in his white robe. The same author gives a curious account of the 'serpent's egg,' worn as a distinguishing badge by the Druids. It was formed, he says, by the poisonous spittle of a great many serpents twined together. Gathered at moonlight, and afterwards worn in the bosom, it was a mighty talisman. All these particulars refer properly to the Druids of Gaul, but Cæsar's testimony leaves no doubt that the Druidism of Britain was essentially the same. According to Whitley Stokes, the Druids never were in Ireland a hierarchy or separate class, as they are said to have been in Britain; but merely a species of wizards, enchanters, or sorcerers.

In all the countries anciently inhabited by Celts, there are found rude structures of stone, one of the most common forms of which is the so-called *Dolmen* (q.v.). The older archaeologists—e.g. Stukeley—assumed that these were Druidical altars, but there is no proof that such was their destination or origin: similar structures are found in Scandinavia and other parts of the Continent. The same doubts prevail as to the larger monuments of this kind—the supposed Druidical temples of Carnac in Brittany, and of Stonehenge (q.v.; and see **STANDING STONES**). Speaking more generally, the historians and archaeologists of the present day do not profess to know nearly so much about the Druids as did those who wrote concerning them in a previous generation. See Rhys, *Celtic Heathendom* (1888); D'Arbois de Jubainville, *Les Druides* (1906).

Drum (Ger. *trommel*; Fr. *tambour*, a modification of *tabour*; *timbral* and *tambourine* are other forms of the word *tabour* or *tambour*), an instrument of percussion, in which a skin of parchment, stretched on a frame of wood or metal, is beaten with an instrument called a drumstick. There are three varieties of the drum: the kettle-drum, the side-drum, and the bass-drum. The first is the only one which can really claim to be a musical instrument, playing a definite note in harmony with the music it accompanies. The kettle-drum (Fr. *timbale*, Ger. *pauke*, Ital. *timpano*) consists of a kettle, or shell, of brass or copper, generally

hemispherical, over the mouth of which the skin is stretched by means of an iron ring, which is also provided with screws and keys for tightening the skin to tune it to any note within its compass. Two (often three or more) are required in a full orchestra; the larger should have a compass from F to C, the smaller from B \flat to F on the bass staff; and they require to be tuned to the proper notes, as indicated in the music. They are played upon with whalebone sticks, having at one end a wooden button covered with sponge or other soft material. The *roll*, a most effective part of its music, is performed with single alternate and very rapid strokes of the sticks, about one-fourth of the diameter from one side. The only military use made of the kettle-drum is in cavalry bands, which carry two, possibly because two are more easily balanced on a horse's shoulders than one, rather than from any musical reason.

The side-drum, or snare-drum, is more essentially a military instrument, though sometimes also used in orchestras. It consists of a brass or wood cylinder, with a skin head at each end. These are tightened by means of hoops over the heads, laced with an endless cord passing zigzag-wise from head to head, and braced with leather braces, or more usually with rods and screws. Across the lower end several catgut cords, or snares, are tightly stretched in contact with the skin, causing a rattle when the other end is beaten. When anything is put between these snares and the skin to prevent the rattle, the drum is said to be *muffled*, and is so used at funerals. It is played upon on the centre of the upper end by means of two hard wood sticks with a knob at one end. The *roll* for the side-drum consists in striking two blows alternately with each stick. It is called *daddy-mammy*, from the sound. The side-drum was formerly used as a signal instrument, and the *drummer* is still an army institution (see *BAND*); but the Bugle (q.v.) does the signalling, the drum only being used with the music in marching.

The bass-drum (Ital. *gran tamburo* or *gran cassa*, Fr. *grosse caisse*) is of similar construction, having (commonly) two heads. The stick has a soft round knob. The centre of the head is struck. The side and bass drums being only used to mark the rhythm of the music, are not tuned to any particular note. The orchestral bass-drum is very often made much larger in diameter than the military instrument, and with a shorter cylinder.

A *Drum-head Court-martial*, so called because originally held round the big drum, is a hasty council or court-martial held in the field when it is necessary to punish an offender on the spot and without delay. By the Army Act of 1881 a *Summary Court-martial* was instituted to take its place in the British army.

The Tambourine (q.v.) is another species of drum. The ancient Romans used small hand-drums—some resembling tambourines and others kettle-drums—in their religious dances; and the Parthians are said to have used them in war to give signals. They are believed to have been first introduced to western Europe by the Crusaders.

Drum, a Celtic word meaning the back, and applied to a small hill or ridge of hills, enters into the composition of many place-names, especially in Ireland and Scotland, as *Drumcondra*, *Drumglass*, *Drumsheugh*.

Drumclog, a moorland tract in Lanarkshire, on the borders of Ayrshire, 6 miles SW. of Strathaven. Here, 2½ miles E. of Loudon Hill, Claverhouse was defeated on 1st June 1679 in a skirmish with a party of 200 Covenanters, vividly described in Scott's *Old Mortality*. A monument marks the scene of the encounter.

Drum-major, the old title (till 1878) of the sergeant-drummer who commands the drummers, marches at the head of the battalion, and sets the pace. See *BAND*.

Drummond, HENRY, biologist and theologian, was born at Stirling in 1851, and studied at the University of Edinburgh and the Theological College of the Free Church; and in 1877 was appointed lecturer on Natural Science, and in 1884, professor of Natural Science at the Free Church College in Glasgow. He had travelled in the Rocky Mountains, in Central Africa, Japan, the New Hebrides, and Australia. In his book on *Natural Law in the Spiritual World* he sought by analogical arguments to reconcile evangelical Christianity with the doctrine of evolution. The book, published in 1883, reached in ten years a 29th edition; and was followed in 1894 by *The Ascent of Man*, an attempt to christianise evolution by laying stress on altruistic elements in natural selection, which he called 'the struggle for the life of others.' Other publications were a charming work on *Tropical Africa* (1888; 20th thousand 1890), followed by a series of small books, *The Greatest Thing in the World*, *Pax Vobiscum*, &c.; and he wrote *CREATION* for a former edition of this Encyclopædia. He died 11th March 1897. See *Life* by G. A. Smith (1899).

Drummond, THOMAS, R. E., born at Edinburgh in 1797, in 1820 joined the ordnance survey, whose work was facilitated by his improved heliostat and his adaptation of the lime-light (the so-called 'Drummond Light'). He became head of the boundary commission under the Reform Bill; private secretary to Lord Althorp, Chancellor of the Exchequer, in 1833; and Under-secretary for Ireland in 1835—a post in which he at once gained the confidence and affection of the people. His memorable saying, 'Property has its duties as well as its rights,' dates from 1838. He died 15th April 1840, in Dublin, where, alone of English secretaries, he lies in a grave of his own choosing among the people he was sent to govern. See the *Life* by Barry O'Brien (1889).

Drummond, WILLIAM, OF HAWTHORNDEN, a poet of considerable celebrity, was descended from an ancient Scottish family, and was born at his father's seat at Hawthornden, near Edinburgh, 13th December 1585. He was educated at the High School of Edinburgh, and afterwards at the university of that city, where he graduated Master of Arts in 1605. He next studied law and general literature at Bourges and Paris, and on his father's death in 1610 retired to Hawthornden, which, according to the learned Ruddiman, 'was a sweet and solitary seat, and very fit and proper for the muses.' He devoted his life to poetry and mechanical experiments. He was on the point of marrying Mary Cunningham of Barns, when she died in 1614 or 1615. He married Elizabeth Logan in 1632. He had to subscribe to the Covenant, but witnessed its triumph with a sinking of heart that the most sarcastic verses in manuscript could not relieve. He died 4th December 1649; his death, it is said, being hastened by his excessive grief for the fate of Charles I. Drummond enjoyed the friendship of many of his contemporaries, including Drayton, Montrose, and the great Ben Jonson, the last of whom paid him a memorable visit at Hawthornden in 1618-19. The two men were unlike in everything save that both were genuine poets, and Drummond's *Notes of the greater man's talk* (in Herford and Simpson's ed. of Jonson, i. 1925) is one of the most interesting chapters of literary history. His principal works are *Tears on the Death of Mæliades*—Prince Henry—(1613); *Poems: Amorous, Funerall, Divine, Pastorall, in Sonnets, Songs, Sottaines*,

Madrigals (1616); *Forth Feasting* (1617); and *Flowers of Sion* (1623). His prose writings include a History of Scotland, known as the *History of the Five Jameses*, as well as some political tracts.

Drummond's verse abounds in the conceits, antitheses, and hyperboles of the period, and gives indication of a mind given to the luxury of melancholy. His sonnets are the best specimens of his muse. His mastery of different rhythms reveals his learning and the labour he gave to his verse. *The Cypress Grove*, published with *Flowers of Sion* (reprinted 1907), is a masterpiece of 17th century prose.

His poems were edited in 1832 (Martland Club), in 1833 (by Peter Cunningham), in 1857 (by W. D. Turnbull), in 1894 (by Wm. C. Ward), and in 1913 (by Professor Kastner). The rude macaronic, *Polemo-Middunia*, is often attributed to Drummond. See the learned and exhaustive Life by Professor Masson (1873).

Drummond Island, most westerly of the Manitoulin chain in Lake Huron, belonging to Michigan, measures 20 miles by 10.

Drunkennes. See INTOXICATION, ALCOHOLISM, DIPSOMANIA, INEBRIATES, and TEMPERANCE.

Drupe, in Botany, a succulent fruit containing a single seed or kernel, usually inclosed in a hard 'stone,' the *endocarp*. The succulent part is the *mesocarp*, the skin the *epicarp*. Examples are familiar in the fruits generally known as stone-fruits, the peach, plum, cherry, &c. The fruits of the genus *Rubus* (Raspberry, Bramble) are composed of many small aggregated drupes upon a common receptacle. See FRUIT.

Drury, DRU, a silversmith of London, was born 4th February 1725. He was devoted to the study of entomology and to collecting exotic insects, and published *Illustrations of Natural History* (3 vols. 1770-82, with upwards of 240 figures of exotic insects). His *Illustrations of Exotic Entomology* was edited in 1837 by J. O. Westwood, and appeared with nearly 700 figures by Moses Harris. Drury died 15th December 1803.

Drury-lane Theatre was first opened in 1663, by Killigrew, though earlier theatres had stood in Drury Lane. Killigrew's house was burned in 1672, and a new building, by Wren, was opened in 1674. In 1791 it was pulled down. The third theatre, completed in 1794, was burned down in 1806. The fourth was inaugurated in 1812 with a prologue by Lord Byron, the advertisement for which gave rise to the famous *Rejected Addresses*. Among proprietors and managers have been Cibber, Garrick, who opened the theatre in 1747 with Dr Johnson's prologue, Sheridan, and Macready; and most of the great English actors have trod the boards which, during and after the management (1879-96) of Sir Augustus Harris, were largely given over to pantomimes and spectacular pieces.

Druses, a remarkable people of Syria, forming three groups—the largest in Jebel Druz or Haurân (q.v.), a mountain district S. of Damascus; the second in southern Lebanon (q.v.); and the third on the western slopes of Anti-Lebanon and about Hermon. Many of the second and third groups migrated to the Haurân, as being too much dominated by Christian authority in Lebanon and Anti-Lebanon. A good many have emigrated to America. Conflicting statements as to their origin indicate probably a mixture of races. According to their own tradition, they were Arab tribes from Yemen who migrated to Mesopotamia, thence to the neighbourhood of Aleppo, where Darazi found them, and whence they came south. Another tradition traces their origin to the Cuthites (Karduchi or Kurds), with whom, after the second captivity of Israel, Esarhaddon re-peopled the wasted strongholds of Samaria. More than a thousand years later, the

Mardi, a warlike tribe of Persian extraction, were transplanted thither by Constantine IV., in 686 A.D., to the number of 12,000, to act as a bulwark against Mohammedan invasion. The Arabs also, in sweeping through the mountain-fastnesses, left a permanent impression there. Thus, according to this view, Cuthites, Mardi, and Arabs, or rather Mohammedans of various races, combined to form that strange being—the modern Druse.

The nationality of these mountaineers having been consolidated, their peculiar and mysterious religion began gradually to be developed. Hakim Biamr Allah, or Biamrillah, one of the Fatimite khalifs of Egypt, and a Nero in cruelty, was the author of this system. He affirmed that he was the representative of God, and, having enlisted his confessor, Darazi, in his cause, he prepared to propound his doctrine. In the 407th year of the Hegira (1029 A.D.), the divine nature of Hakim, or rather the incarnation of the Spirit of God in him, was publicly announced at Cairo. This revelation, however, was unfavourably received by the mob. Hakim's confessor, Darazi, narrowly escaped the fate of a martyr to the impostures of his master. Retiring, however, he established himself on the western slopes of Hermon near Hasbeya, and there began to inculcate the principles of the new faith; and although he never acquired any mastery over the sympathies of the mountaineers, he at least in all probability left his name to them. Hamzé, a Persian mystic, and successively the disciple and vizier of Hakim, introduced into the newly promulgated religion all the elements of attraction and strength which it possesses; and him the Druses venerate as the actual founder of their faith.

The Druses form one of the very few sects among whom proselytism is discouraged. They are remarkable conservatists. For 800 years they have maintained a distinct religious and political independence and nationality. Into their faith the doctrines of the Pentateuch, the Christian gospel, the Koran, and the Sufi allegories are wonderfully interwoven. The following are their seven great principles: (1) Veracity (to each other only); (2) mutual protection and resistance; (3) renunciation of all other religions; (4) separation from all who are in error; (5) recognition of the unity of God; (6) resignation to his will; (7) obedience to the commands of God. They believe in one God in whom there are no parts, to whom they ascribe no attributes, before whom the tongue ceases to utter, the eyes to behold, but who has revealed himself ten times upon the earth under the form and name of mortal men. In Hakim, so Hamzé taught, had God revealed himself for the tenth and last time; there have been sixty-nine minor manifestations. They also believe that the number of existing souls never varies, and that all the souls in life now have lived, vested in some human form, from the beginning of the world, and will so continue to exist till the end of it; that when a man dies, his soul puts on a fresh humanity, which occupies a rank in moral dignity corresponding to the purity or impurity of the past life. When the soul has been purified from every stain, there will come a period of rest. Prayer is looked upon as an interference with the work of the Creator. The resurrection will be ushered in by war between the Mohammedans and Christians, and the Druses only wait for an Armageddon in which they believe they are destined to take a prominent part. As a religious body, the Druses are divided into two classes; the *Äkals*, or those initiated into the Druse mysteries; and the *Djahils*, the uninitiated. The former do not adorn themselves with gold, or wear silk, or embroidered garments; they forbear using wine,

spirits, tobacco, and other luxuries. Yet the Akal is taught that when necessary, equivocation, or even falsehood, may be practised.

The most remarkable man produced by the Druses in the beginning of the 17th century has been the Emir Fakr-ed-din, who annexed Beyrout and Sidon, and threatened Damascus, and who was executed by the Turks. When Emir Beshir was chosen sheikh of the Druses in 1789, the authority of the Porte was only nominal in the Lebanon; by the help of Egypt he subdued his rivals. The Turks instigated the Druses to revolt against Egypt, and the final struggle between the Turks and Egyptians culminated in the defeat of the latter, owing to the assistance rendered to the Sultan by England, and Emir Beshir was exiled. After this, the Maronite Christians and the Druses took to murdering each other, and the strife reached its climax in 1860. From May to October of that year, accounts of the fearful barbarities practised by the Druses upon the Maronites followed each other with appalling frequency, until the indignation of Europe was roused against them. A conference of the five Powers which had guaranteed the independence of Turkey met at Paris, and a force (one-half French) and a European Commission were sent to Syria. They could not, however, get at the Druses, who retired into the Desert of the Haurân. It was ascertained beyond all doubt that the Turks and the low fanatical mob of Damascus were mainly chargeable with the crimes that had been committed; and that the retaliations of the Maronites were equally vindictive and horrible. Punishment was inflicted on those who were most to blame. In 1864 the commissioners drew up a constitution for the Lebanon, which was to be ruled by a Christian governor, appointed by the Porte; and to be divided into seven districts, under chiefs of the prevalent religion in each. Daoud Pasha was appointed governor, under whom and his successors disturbing elements were usually kept in check. The Druses of the Haurân were in active rebellion in 1896, but after some severe fighting agreed to pay taxes and serve as frontier guards in their own district. After further fighting in 1910, they accepted liability to military service. When Syria passed under a French mandate, Great Lebanon and Jebel Druz (Haurân) became states, and the Druses resisted French rule as they had Turkish. The Druses of the Haurân are reckoned at upwards of 50,000, those of Lebanon at 50,000, those of Anti-Libanus at somewhat less. The Haurân is now opened up by railway, and commercial interests have been developed, whereby the habits and customs of the Druses are being modified. They are a brave, handsome, and industrious people, and can almost all read and write. They abstain from excesses, never taste wine or tobacco, polygamy is unknown, the women are virtuous, and divorces are uncommon though simple enough, consisting in the husband telling his wife three times that she had better go back to her mother. They had no superior educational establishment until Daoud Pasha founded and endowed one at Abey. They have, with incredible toil, carried the soil of the valleys up and along the hillsides, which are laid out in terraces, planted with mulberry, olive, and vine. Their chief trade is the manufacture of silk, chiefly at Shimlan, 3000 feet above sea-level. Corn is also raised, though in very small quantity. Deir-el-kamar (q.v.) is the principal town, but of late Bakhlin, 6 miles distant, has been the Druse headquarters. Kunawat is the chief town of the Druses of the Haurân.

See ANSAËS; the Earl of Carnarvon's *Druses of the Lebanon* (1860); De Saey's *Exposé de la Religion des Druses* (1828); Churchill's *Ten Years' Residence in Mount Lebanon* (1853), and *Druses and Maronites* (1862);

Laurence Oliphant's *Land of Gilead* (1880), and *Haifa* (1887); Miss G. L. Bell's *The Desert and the Sown* (1919).

Drusus, the name of a distinguished family of the gens Livia, and of some members of the Claudian gens. The most conspicuous of the Drusi were (1) M. Livius Drusus, tribune of the people in 122 B.C., the opponent of the democratic policy of his colleague, C. Gracchus. (2) His son of the same name, who, though identified by birth and sympathy with the patricians, renewed some of the most liberal measures of the Gracchi, and advocated the claims of the Italians to Roman citizenship. He was assassinated in 91 B.C., just before the outbreak of the Social War. (3) The most illustrious of the Drusi was Nero Claudius Drusus, commonly called Drusus Senior, the stepson of the Emperor Augustus, and younger brother of the Emperor Tiberius. His campaign against the Rhaeti and other Alpine tribes (15 B.C.) is celebrated by Horace (*Odes*, iv. 4). Until his death in 9 B.C. he was engaged chiefly in establishing the Roman supremacy in Germany. The 'Fossa Drusiana,' a canal joining the Rhine with the Yssel, and other engineering works were constructed by his direction. For his exploits in Germany, Drusus was rewarded with the title of Germanicus, but the celebrated Germanicus (q.v.) was his son.

Dryads, wood-nymphs in Greek mythology. See NYMPHS. See also HAMADRYADS.

Dry-bulb. See HYGROMETER, THERMOMETER.

Dryburgh, a beautiful ruined Premonstratensian abbey, in Berwickshire, 5 miles ESE. of Melrose, on the Tweed, here crossed by a suspension bridge. It contains the dust of Sir Walter Scott and his son-in-law Lockhart; whilst Ebenezer Erskine (q.v.) is said to have been born close by. The abbey was founded in 1150 by David I., and not, as is commonly stated, by Hugh de Morville. It is said to have been more or less destroyed in 1322 and 1385; by Bowes and Latoun in 1544, and by the Earl of Hertford in 1545. See Spottiswoode's *Liber de Dryburgh* (Bannatyne Club, 1847).

Dryden, JOHN, was born at Aldwinkle, in Northamptonshire, on the 9th of August 1631. His father, Erasmus Dryden (the name until the poet's manhood was more usually spelt Driden), was a cadet of a family of Border origin, which some generations before had settled at Canons Ashby, in the same county, but at some distance from Aldwinkle. The poet's mother was Mary Pickering, and it was at her father's house (the rectory of the parish of Aldwinkle All Saints) that Dryden was born. Very little is known of his early youth, but he seems to have passed it chiefly at Tichmarsh, near Aldwinkle, where his maternal grandfather also had property. He was entered at Westminster School when he was twelve years old, and proceeded to Trinity College, Cambridge, when he was nineteen, being matriculated on July 16, and elected to a Westminster scholarship on October 2. On July 19, 1652, he was punished slightly for some offence against discipline, and this is all that is positively known about his Cambridge career, except that he took his bachelor's degree in 1654. He never proceeded to the M.A., preferring to take that degree from Lambeth, and he seems on the whole to have had little affection for Cambridge. His father died in the same year (1654), and Dryden succeeded to two-thirds, and after his mother's death to the whole, of a small estate at Blakesley near Canons Ashby, then worth £60 a year, where he seems never to have resided. He, after the fashion of the time, continued to live at Cambridge till 1667, and then he went to London. Both the Drydens and the Pickeringes were strong parliamentarians, and

Dryden seems to have had some, but vain, hopes of patronage from his cousin Sir Gilbert Pickering, a favourite of Cromwell. It is thought that he began early to do work for the booksellers, especially Herringman, a then frequent employer of young authors; but again we have little or no positive information respecting him till December 1, 1663, when he married Lady Elizabeth Howard, eldest daughter of the Earl of Berkshire, and sister of two not unknown men of letters who were Dryden's friends. Much scandal has been talked about this marriage on absolutely no solid ground, but it seems probable that it was not wholly happy, and that Lady Elizabeth, whose intellect was certainly not strong, may have had a bad temper. Three sons, Charles, John, and Erasmus Henry, were the offspring, and from this time Dryden occasionally resided at his father-in-law's Wiltshire seat of Charlton. He had several London residences, the best known of which was in Gerrard Street, Soho, a house now marked with a tablet. Very shortly after the wedding, Pepys on the 3d of February 1664 met Dryden, 'the poet I knew at Cambridge,' at Will's Coffee-house, and this is the first of the personal notices (very few in number) that we have of the poet.

The dramatic work of which further notice will be taken shortly now occupied Dryden almost entirely for many years—for no less than fourteen he wrote next to nothing but drama. He was made poet-laureate and historiographer-royal in 1670, the emoluments of which places (£200 a year) were increased by a pension of £100 in 1679. Some literary disputes and a quarrel with the malevolent Rochester, which brought Dryden on the 8th December 1679 a cudgelling by masked bravoës, are almost the only events of importance in this long period. The disturbances in public opinion which followed the Popish Plot provoked the splendid series of satires beginning with *Absalom and Achitophel*, and brought an increasing storm of libels in prose and verse on Dryden's head from the other side. In 1683, as part compensation for great arrears in his salary, and perhaps also as reward for his political services, a collectorship of customs in the port of London was granted him, but the value of this place is not known. In the epidemic of conversion which followed the accession of James II., Dryden was one of the chief seceders from the Church of England, and his sincerity in this act has been violently impugned. Controversy on such a point being here impossible, it must be sufficient to say that his previous state of mind on the subject appears to have been exactly that half-scepticism, with a kind of yearning for authoritative certainty, which has constantly disposed men to Roman Catholicism; that he gained (as can be proved) not one penny by the change of faith; and that he adhered to it when others 'reverted,' and when his own constancy inflicted the heaviest loss upon him. At the Revolution he did not take the oaths, and thus lost all his places and pensions. To supply this loss, he then returned to play-writing, and to the less uncongenial, if not quite so profitable work of translation. During the last ten years of his life (which saw the production of his famous translation of *Virgil*, and of the collection of his most accomplished verse called the *Fables*) we have, thanks to the accidental preservation of letters, a few more personal details about Dryden than at other times. Almost immediately after the publication of the last-named volume (at the end of 1699), an attack of gout, from which disease he had always suffered much, set in, and resulting in mortification of the toe, carried him off on May-day 1700. He was splendidly buried in Westminster Abbey. All his sons died before their mother, who

lived till 1714, and was insane at the time of her death. The youngest, however, Erasmus Henry, had succeeded to the family honours and baronetcy, and to the estate of Canons Ashby, which, by a female descent, are still in the name.

Dryden's great literary work began early, though not plentifully or very promisingly, with some poems in the 'metaphysical' manner of Donne and Cleveland; but his stanzas on the death of Cromwell, though lacking ease and flow, have great merit, and the group of panegyric poems, written after the Restoration, beginning with *Astræa Redux* and ending with *Annus Mirabilis*, exhibit wonderful command of a style of verse not hitherto attempted. Then, as has been said, Dryden turned all his energies for many years into dramatic work, which he confesses to have been distasteful to him, and which was done for profit simply. Between *The Wild Gallant* (1663) and *Love Triumphant* (1694) he produced a great number of plays, the best of which are the *Conquest of Granada* (1670), *Marriage à la Mode* (1672), *Aurungzebe* (1675), *All for Love* (1677), *The Spanish Friar* (1681), and *Don Sebastian* (1689). The comedies are disfigured by a double portion of the license in language and situation which was common at the time, and the earlier tragedies by their unnatural rhymed dialogue, and by the frantic rant of style which was fashionable; but they occasionally contain, especially in interspersed lyrics, and in a few set speeches, extremely fine poetry. It was Dryden's practice, too, to prefix or append to the published versions of these plays, essays which developed his astonishing talent for prose, which may be said to have produced English literary criticism, and which contain passages unsurpassed of their kind. It can hardly, however, be said that his full powers were shown till the appearance, in his fiftieth year, of *Absalom and Achitophel*. This, with his contribution to its second part, *The Medal*, *Macfiecknoe* (a satire on the whig Shadwell), and with the didactic poems of *Religio Laici* (exhibiting the sentiments of a half-sceptical Anglican), and *The Hind and the Panther*, written after, and to justify his conversion, contain by far the most powerful work of the satiric and didactic kind in English. The rhymed heroic couplet is here adjusted to the purposes of invective, insinuation, and argument with unmatched dexterity, and is charged with an overwhelming force.

Besides these, Dryden exercised himself in various minor kinds, such, for instance, as the preparation of prologues and epilogues for other men's plays as well as his own, and in the composition of Pindaric odes, one of which, that on Mrs Anne Killigrew, shares with his own later 'Alexander's Feast' the position of the best work of this particular kind. He also began the practice of translating the classics, which led finally to the great translation of *Virgil* already referred to, and to his scarcely less popular *Juvenal*; and this in its turn led him to what he also called 'translation' of authors other than the classics, such as Chaucer and Boccaccio. These later paraphrases formed the nucleus of the *Fables*, in which the magnificence, the variety, and the flexibility of his poetical style appear as clearly as its vigour and weight appear in the satires and didactic pieces. The dedication of the *Fables* in particular, addressed to the Duchess of Ormond, when the author was nearly seventy, has a stately beauty nowhere exceeded. His general poetical characteristics, as far as they can be summed up in a very brief space, may be said to be the faculty of clothing in splendid verse of a pattern quite unknown before him, and never in its own way equalled since, almost any subject that presented itself for treatment. Of inventive, or rather creative origin-

ality he had, save as to matters of form, little; and the finest and most ethereal graces of poetry were not his. But he is hardly to be excelled in massive yet not ungraceful splendour of style, and not to be excelled at all in variety of accomplishment. His prose, less splendid than his poetry, is of equal merit as a vehicle of literature, and like his verse, is almost entirely of his own finding out. For a combination of familiarity and finish it has not yet been surpassed.

All earlier editions of Dryden's works were superseded by Sir Walter Scott's in 1808, reprinted in 1821, and in 1883-93 re-edited (in 18 vols.) by Professor Saintsbury. Those of Bell, Mitford, Christie, Hooper, and Sargeant (1910) are also useful. Churton Collins edited the *Satires* in 1893, and W. P. Ker the *Essays* in 1900. See *Lives* by Scott and Saintsbury (1881), Garnett's *Age of Dryden* (1896), Ward in the 'Cambridge English Literature' (vol. viii. 1912), Verrall's *Lectures on Dryden* (1914), Allardyce Nicoll's *Dryden and his Poetry* (1923), Pendlebury's *Dryden's Heroic Plays* (1923).

Dry-farming, a very important system of agriculture, first studied in the United States, and now largely practised there, is being introduced into South Africa and elsewhere in regions which have a light rainfall, and promises to enhance the value of large areas in many parts of the world. The principle is the conservation of the rain in the soil; and even in lands with a very small rainfall, satisfactory harvests can be secured by reducing the loss through evaporation to a minimum, and utilising the rain as completely as possible. Where one year's rainfall is insufficient for a harvest, methods can be employed for retaining one year's rainfall in the soil, so that in the second year nearly two years' rain is available for the crop. The method is to keep the surface-soil constantly in a loose state by careful tillage, so as to check as much as possible the capillary process which brings the moisture from below by small channels between the soil particles, and so carries on progressive evaporation to a very considerable depth. If one-half of the land carries the crop, the other may lie fallow; and its surface being kept constantly loose by the harrow or other apparatus, the first year's rainfall is retained in the ground to serve the second year's crop. Harrowing must immediately follow ploughing; and as a shower consolidates the surface-soil, and so promotes capillary evaporation from below, harrowing must always follow the falling of rain.

Drygalski, ERICH DAGOBERT VON, German polar explorer, was born 9th February 1865 at Königsberg, and studied there, and at Bonn, Leipzig, and Berlin. In 1891-93 he headed expeditions to western Greenland to study land ice. He became extraordinary professor at Berlin in 1899. In 1902-3 he led the 'Gauss' Antarctic expedition, which visited Kaiser Wilhelm II. Land, and obtained valuable scientific results.

Drying-machines are of many kinds. For the drying of long webs of calico and other fabrics, a machine, consisting of a series of metal cylinders revolving in an iron frame, and heated internally with steam, is employed. Centrifugal drying-machines or hydro-extractors consist of a circular wire-basket mounted on a shaft and set in a close metal jacket. The fabrics or stuffs to be dried are placed in the basket, which revolves at a speed varying from 700 to 2000 revolutions per minute. The water flies off by the centrifugal action, and escapes from the enclosing cylinder by a discharge-pipe. In the Blackman air-propeller, the wool or other textile is spread over a perforated surface which is in connection with a revolving propeller, with peculiarly shaped blades, placed at the top of a vertical trunk or shaft. This apparatus dries the wool by drawing heated air through it. There

are special machines or methods for yarn, for use in paper-making, &c., elsewhere described.

Dryobalanops, a small genus of Dipterocarpaceae, found in Borneo and Sumatra. The young leaves are red and drooping, and raise themselves as they mature. The sepals form long wings, which aid wind-dispersal of the fruit. Borneo or Sumatra camphor, valued in China, occurs in cracks in the wood.

Dryophis, a genus of non-venomous snakes in the sub-order Colubrimorphes, allied to Dendrophis; and, like that genus, of very elongated form, and mostly arboreal in habit. They are distinguished by a curious prolongation of the snout, which in some is slender, in some leaf-like. They are natives of tropical America and West Africa. The elongated snout is very marked in the associated genus *Langaha*.

Dryopithecus, a European Miocene fossil ape, thought by some to be near the direct line of man's descent.

Dry-point. See ENGRAVING.

Dry Rot, a kind of decay, often very rapid, to which timber is subject. Its name is misleading, since this decay is associated with the presence of water, such as is found in unseasoned wood. It has proved ruinous to many valuable edifices, and has been the cause of many serious accidents. The ends of joists are often affected by it, so that upon being burdened with even a slight additional load, they are ready to break off by the wall; and the process of destruction has often gone far without a suspicion being entertained of anything wrong. Dry rot is occasioned by Fungi, the *mycelium* of which penetrates the substance of the timber, destroying its texture, and reducing it to a fragile or even friable mass. *Merulius lacrymans* and *Polyporus destructor* are species very commonly productive of this mischief; the first being by far the most common and formidable. Its German name is *Hauschwamm*. *Merulius lacrymans* first appears in small white points; a filamentous substance radiating from these gradually forms broad patches, sometimes many feet in diameter; from these long creeping shoots often proceed, and a network of filaments penetrates into every crevice, filling the whole mass of the timber with delicate filaments, which destroy the cohesion of its fibres. It often appears in the form of leathery laminae.

Of the causes of dry rot, stagnation of air, as behind a wainscot or under a floor, is certainly one of the chief, and a knowledge of this fact suggests means of prevention which may often be easily and most advantageously employed. Another principal cause is insufficient drying of the timber itself; and much of the prevalence of dry rot is not improbably due to the practice of felling trees in spring when the wood is full of sap. Any circumstance which may tend to render the sap acidulous greatly increases the liability to dry rot. The production of fungi takes place with unusual rapidity when by fermentation or otherwise an acidulous condition of organic substances is produced. A fermentation and chemical change in the albuminous constituents of the wood is not improbably the immediate cause of dry rot, providing a soil suitable for the vegetation of fungi.

For the prevention of dry rot various processes have been employed, the object of which is to fill the pores of the wood with some chemical substance. Active inquiry as to methods of preservation of timber began about the middle of the 18th century, and the matter was rendered urgent by the premature decay of the ships of the royal navy at a time of long-maintained conflict. No satisfactory method was discovered, however, until the development of the railway and telegraph system led to

further inquiry with the view of preventing the destruction of sleepers and telegraph poles. The various processes of kyanising (corrosive sublimate of bichloride of mercury), margarysing (sulphate of copper), burnettising (chloride of zinc), have been replaced by the effective method of creosoting, invented by John Bethell in 1838. But without the use of any such means we have abundant evidence that well-seasoned timber, in favourable circumstances, may remain unassailed by fungi for many centuries.

Dual, in Grammar, is the form given in some languages to a noun or a verb when only two things are spoken of. Thus, in Greek, *patēr* is 'father'; *patere*, 'two fathers'; *puteres*, 'fathers.' Sanskrit, ancient Greek, Arabic, and Hebrew have the dual number, the last only in nouns. Modern Greek has lost the dual. The only trace of it in Latin is in the two words *duo*, 'two,' and *ambo*, 'both.' It is for the most part wanting in the Teutonic languages, but ancient Gothic had a dual form of the verb, and in Old English there were separate forms of pronoun for 'we two' (*wit*) and 'ye two' (*git*).

Dual Control. See EGYPT.

Dualism is the name given to a philosophical theory, according to which some two principles, of different nature, original, and incapable of being derived the one from the other, lie at the bottom of everything; as, for example, the ideal and the real, or the material and the thinking substance. In a narrower and theological sense, dualism means the assumption of two original beings, a good and an evil, as in the doctrine of Zoroaster (q.v.), or of two distinct principles in man, a bodily and a spiritual. The opposite of dualism is Monism.

Du Barry, MARIE JEANNE GOMARD DE VAUBERNIER, COMTESSE, favourite of Louis XV., was born August 19, 1746, at Vaucouleurs, the daughter of a dressmaker. Coming very young to Paris as Mademoiselle Lange, she became a milliner of more than dubious character, next the mistress of the disreputable Jean, Comte du Barry, by whose means she was presented to Louis XV., already, at sixty years of age, in his dotage of shame. Her handsome face, but still more her piquant if vulgar wit, amused the worn-out dotard, who procured her presentation at court as Comtesse du Barry, in 1769, by marrying her to Guillaume, Comte du Barry, the reprobate brother of her earlier reprobate protector. The Duc de Choiseul attempted to resist her influence, but was soon displaced, while she, with her confidant the Duc d'Aiguillon, governed France. On the death of Louis (1774) she was dismissed from court. In 1793 she was guillotined for wasting the treasures of the state and wearing mourning for the king.

See *Lives* by Vatel (3 vols. 1882-84), R. B. Douglas (1896), Noel Williams (1904), and Saint-André (1915).

Du Bartas. See BARTAS.

Du Bellay. See BELLAY.

Dubitzá, a fortified town of Yugoslavia (Bosnia), on the Unna, in the 16th and 17th centuries a bone of contention between Austria and the Porte; pop. 4000.

Dublin, a maritime county in the province of Leinster, Ireland, containing the metropolis of that country; bounded N. by Meath, E. by the Irish Sea, S. by Wicklow, and W. by Kildare and Meath. It is the smallest but two of the Irish counties, having an area of 354 sq. m., of which $\frac{3}{4}$ ths are arable and $\frac{1}{4}$ th in wood. The coast, from its indentations with creeks and bays, is 70 miles long, and off it lie several islands. Dublin Bay, one of the finest in the kingdom, is 6 miles broad, with a sweep of 16 miles, and is generally deep. There are precipitous headlands, over 500 feet high, both at the north and south ends; and the bay is remarkably picturesque. The coast

of Dublin is undefended by fortifications. Being within the Pale, the county was well fortified in medieval times, and the remains of many strongholds still exist. The surface of the country inland is mostly a level, rich plain, with slight undulations, but rising in the south in a hill-range; the highest point of which is Kippure, 2473 feet. North of this range the only prominent eminence is the Hill of Howth, 560 feet. The only river of note is the Liffey, which runs through Dublin city into Dublin Bay. The chief rocks are carboniferous limestone (calp prevailing round the city), granite, and some metamorphic rocks and greenstones. There are lead-mines near the Scalp. Granite and black limestone are much used in building. There is an important mineral spring (sulphur)—resembling that of Harrogate—at Lucan. The climate is mild. The soil is generally a calcareous gravelly clay. In the north and west are grazing and meadow farms, and around Dublin city villas, dairy-farms, and nursery-gardens. Dublin is one of the best-cultivated counties in Ireland, though much under one-third is usually in crop. Along the coast there are important fisheries of herrings, turbot, brill, sole, plaice, cod, haddock, and whiting. The manufactures are few and unimportant, save at Balbriggan, which is noted for its hosiery. The towns with a population of more than 10,000 are Dublin (q.v.), and its suburbs of Rathmines (38,190), Pembroke (29,260), Blackrock (8719), and Kingstown (q.v.). Pop. (1841) 372,775; (1881) 418,910; (1891) 419,411; (1901) 448,206; (1911) 477,196, of whom 78 per cent. are Roman Catholics. The county at large sends six members to the Free State parliament, not including city and university members. See county history by F. Elrington Ball (1902 *et seq.*).

Dublin, the capital of Ireland, stands on the river Liffey, where it falls into Dublin Bay, in 53° 20' 38" N. lat., and 6° 17' 30" W. long. By the Municipal Act of 1900 several urban districts were added, so that the area of the city is now 7911 acres. The population (1911) was 304,802. It is represented by twelve members in the Free State parliament, four for each of its three divisions, Dublin University by four, and the National University (which has colleges also in Galway and Cork) by four. Dublin is governed by a corporation consisting of Lord Mayor, twenty aldermen, and sixty town councillors.

Dublin stands on the low-lying shores of Dublin Bay and banks of the river Liffey, which flows through it from west to east, cutting the city into two well-defined divisions, north and south sides. The river is spanned by ten bridges for passenger and general traffic. The city is remarkable for the fine proportions of its main thoroughfares, the beauty of its surroundings, particularly on the south, where the mountains come into the view of the streets, and the magnificence of its public buildings. Two canals connect the Liffey harbour with the Shannon, one the Royal, bounding the city on the north, and the other the Grand, on the south, along which 'circular' roads may be said to run, covering a length of some 9 miles. The river is banked throughout by fine lines of walls and quays, the South Wall, a really great work, being $3\frac{1}{2}$ miles long, and running far into Dublin Bay to the Pigeon House Light. Further protection is given to the harbour by the Bull Wall and the rebuilding and extension of the North Wall against the encroachment of the sands of the north shore. The latter is a fine work, and now extends eastward from Butt Bridge for a distance of 2500 yards.

Down to the Act of Union the north side was the chief residential portion of the city; but from early in the last century fashion changed, town houses of the country gentry were given up, and patronage was extended to the south side, so that now the suburbs extend along the whole coast to

Kingstown, and for miles westward. Many of the old houses still retain fine examples of 18th-century decoration, especially of the Italian stucco-work on ceilings and walls, for which the city was so noted. The finest thoroughfare, Sackville Street, is on the north side, being 600 yards in length and 40 in width; but the view is much interfered with by tram-poles and monuments, especially the latter in Nelson's Pillar, a fine structure 134 feet high and crowned by a statue, in the centre of the street, and O'Connell's monument, a magnificent work by Foley, at the south end. The reconstructed bridge here, the main crossing for traffic, is of noble proportions, and called after the name of the great 'Liberator.'

The public buildings nearly all date from the 18th century, when architectural schemes on a vast scale set in and were carried out at government expense. These are all of classical design, and give a stately grace and dignity to the city. Among the chief are the Bank of Ireland, facing Trinity College, at the foot of Dame Street, nearly to which the tidal waters of the river at one time found their way. The buildings cover an area of about $1\frac{1}{2}$ acres, and were erected at varying intervals at a cost of £95,000. The main front is Ionic, and forms three sides of a receding square, with an open colonnade extending to the wings, which are connected with the east and west faces by curtain walls. The east front was built as an entrance to the House of Lords, and this chamber is preserved in its original condition. The House of Commons, which opened on the main entrance, was removed in the alterations made in 1802, after the purchase of the buildings from the government for a sum of £40,000. The principal hall, now the cash-office, is of fine proportions, and stands on the site of the original Court of Requests. Trinity College occupies a fine site in the centre of the city, its walls embracing an area of 28 acres. It consists of several courts running from its west entrance eastwards, and on the south side of these lie through the entire length the fine College Park and Fellows' Gardens. The academic buildings, due chiefly to the public spirit of the Irish houses of parliament in the 18th century, are worthy of such a splendid site, being classic in style, and constructed of massive granite and limestone. The Library (1712-32) is the earliest of these, and measures 270 feet in length. The upper room, extending the entire length of the building, is one of the finest of its kind in Europe, being lit by about 100 windows and fitted in carved oak, with a lofty vaulted pine roof. It contains 368,000 printed volumes and 2000 MSS., among which are many of the rarest kind; the finest is the *Book of Kells*, 'the most beautiful book in the world,' the beauty, intricacy, and colouring of the profuse illuminations being unrivalled. The Schools is one of the finest modern buildings in the British Isles, and is Byzantine Renaissance of the Venetian type in style. The University was founded in 1591, on the lands of the old Augustinian Monastery of All Hallows, which were granted by the Mayor and Corporation of the city for the new institution. The National University was founded in 1908, and occupies the buildings of the superseded Royal University at Earlsfort Terrace, and has constituent colleges in Dublin, Cork, and Galway. The Castle, at the head of Dame Street, consists of two courts, and the buildings have little architectural interest, except perhaps the chapel. The Record Tower is one of the four original towers which with the walls enclosed the Castle area. The Birmingham Tower was rebuilt in 1775. The Castle was till 1922 the official residence of the Viceroy, and the official centre of the government of Ireland. The Law Courts were transferred thither on the destruction

of the Four Courts (1922). The National Museum, Library, Natural History Museum, National Gallery, Leinster House, and the College of Science form a splendid group of buildings and occupy a vast space of ground lying between Kildare Street and Upper and Lower Merrion Streets. The Museum contains the fine Royal Irish Academy collection of Irish antiquities of the Neolithic, Bronze, and Early Christian periods, the whole of which, numbering many thousands of specimens, is perhaps the finest yet brought together in Europe. The Library contains about 200,000 volumes, and is exceptional among the great libraries in being open to readers from 10 A.M. to 10 P.M. The National Gallery is one of the best of the minor European galleries, and has fine examples of the Italian and Dutch schools. The Natural History Museum has one of the most complete national collections of fauna yet made, and several fine specimens of the skeletons of the Irish elk (*Cervus giganteus*). The ceilings, and walls of Leinster House, the old residence of the Dukes of Leinster, now housing the Free State parliament and the Royal Dublin Society, are finely decorated in Italian stucco-work. The society was formed in 1731, and devotes itself to the development of the agricultural industry of Ireland, to scientific and other pursuits. Its great annual Horse Show in August, of world-wide repute, is held in its fine premises at Ball's Bridge, a near suburb of the city. On the north side of the city stood till 1921 the Custom House, the finest building in Dublin, facing the river-month for a distance of 125 yards. The Four Courts, an extensive pile, was also on the north quay, at the west side of the city; the building was fourteen years in hand. Rebuilding was begun soon after its destruction. Kilmainham Hospital, standing farther west, was designed by Sir Christopher Wren, and erected for incapacitated soldiers on the lines of Greenwich Hospital. It is the only one of the great buildings not erected during the somewhat fevered building period of the 18th century. Here the Commander of the Forces in Ireland had his residence.

Dublin is remarkable in possessing two cathedrals belonging to one denomination (Church of Ireland). Christchurch, originally of Danish foundation (in 1038 by Sigtryg, king of the Dublin Danes), is the older of the two, and stood within the city walls. It suffered many vicissitudes, and was in a poor condition in 1870 when its restoration was undertaken at the expense of the late Mr Henry Roe, a Dublin distiller. It is now a very beautiful building within and without, a sum of £200,000 having been spent on the restoration, which took eight years to complete. St Patrick's Cathedral, long the rival of Christchurch and a more stately building, stood without the walls close by, and was erected originally as a collegiate church soon after the Anglo-Norman occupation. Early in the 13th century it was raised to the dignity of a cathedral, with the intention of superseding the earlier foundation. Christchurch, however, maintained its status throughout the subsequent centuries, and after the disestablishment of the Irish Church (1870), it was confirmed as the cathedral of the united dioceses of Dublin and Glendalough, while St Patrick's Cathedral was constituted a national cathedral, representative canons from each diocese in Ireland taking the place of the prebendaries of the old foundation. The latter cathedral was completely restored by Sir Benjamin Lee Guinness at a cost of £150,000. It is particularly associated with the name of its greatest dean, Jonathan Swift, and here he and 'Stella' lie buried side by side. Both cathedrals are now in the heart of the city, surrounded by many poor and mean streets.

Dublin is particularly well supplied with open spaces, the last erected being due to the munificence of Lord Iveagh, who has cleared away a foul nest of courts at the north side of St Patrick's, and converted the site into a well-laid-out public garden. The largest open space within the city is St Stephen's Green, 22 acres in extent; it is beautifully laid out, originally at the expense of Lord Ardilaun, and was presented to the city by him. Without the city on the north side is Phoenix Park, one of the finest in Europe. It embraces an area of 1752 acres, and within it are the Governor-general's official residence (till 1922 the Viceregal Lodge), the Zoological and People's Gardens, and several monuments, the most conspicuous being Wellington's, an obelisk 205 feet high near the east entrance. The park is largely used for sports, and is noted for its reviews held in the so-called 15 acres, which in reality is about 200 acres. Dublin is especially well supplied with hospitals and other similar foundations of all kinds, and few, if any, cities in these islands contain more charitable institutions ministering to the wants of the community.

Dublin is largely an official and residential city, and it contains few industries of any special note. It has, however, the largest brewery in the world. Dublin whisky, too, is famous, especially the pot-still; and its poplin is equally celebrated. The manufacture of this beautiful fabric, a combination of silk and wool, was first established in Dublin at the end of the 17th century by the Huguenot refugees, who fled here after the revocation of the Edict of Nantes. The export trade of Dublin is largely in agricultural produce, and vast quantities of live-stock, fowls, eggs, butter, bacon, and vegetables are shipped for the English markets. There is a very large export trade also in porter, whisky, and mineral waters. Dublin has a fine water-supply, drawn by a double line of pipes from the headwaters of the Vartny River near Roundwood, 24 miles distant from the city. The storage reservoir covers 400 acres, and has a depth of 60 feet; it holds 2,482,800,000 gallons, giving a supply of 12,000,000 gallons daily for 200 days. The embankment is 200 feet in length, 500 feet wide at the base, and 30 feet wide at the top. Another reservoir has been constructed near the older, which is 510 acres in extent, with a supply of 1,259,000,000 gallons. The immediate water-supply of the city is at Stillorgan reservoir, about 5 miles distant, which covers 26 acres, and has a capacity of 100,000,000 gallons, being a nine days' supply. The Rathmines township has its own water-supply at Glensmole, taken from the Dodder River, 7 miles distant. It is held by two reservoirs with a united capacity of 516,000,000 gallons. Down to 1907 the Liffey was the medium of discharge of the whole sewage of the city, the volume of which, owing to the admirable water-supply and improved sanitation, long rendered the bed of the river particularly obnoxious to the inhabitants. In the year named the new main drainage scheme was put into operation. It consists of two great intercepting sewers running under the north and south quays, the north being carried under the bed of the river at Eden quay to join the south drain, and the united stream of sewage is finally discharged into purification-tanks at the Pigeon House. Here it is mixed with milk of lime, and after a period of rest the liquid portion is discharged into the estuary and the sludge into a steamer, by which it is carried out to sea. The total cost of this great work has exceeded half-a-million sterling.

In education Dublin takes a leading place among the cities and towns of the British Islands. While, with the exception of Trinity College, none of its institutions are well endowed, and the great majority are without any endowment, the standard

of education maintained is a high one. Fellowships at Trinity College are awarded after an examination of an exceptionally severe kind, following upon years of long and patient study; but the principle of election without it has recently been introduced to be of partial application. Dublin and the National Universities have schools for the various professions, the former including divinity for students of the Church of Ireland; Maynooth is the seat of theology for the priesthood of the Roman Catholic Church. The College of Surgeons and the College of Physicians are licensed bodies for granting diplomas in medicine, and large numbers of students are trained by them in addition to those attending the university medical schools. The College of Science, already referred to, is a government institution, and affords a complete course of instruction in science as applied to industries and arts. The secondary schools are numerous, and most have been established by private enterprise; all the Roman Catholic schools and training colleges are in the hands of the various teaching orders. A great impetus was given to secondary education by the Intermediate Board (1878). The Primary Schools are under the control of the Irish Ministry of Education, which took over the functions of the National Board of Education, established in 1831. There are four Training Colleges; the Central, in Marlborough, open to all denominations; the Church of Ireland, in Kildare Street; and the Roman Catholic (men) in Drumcondra, and (women) in Blackrock. Tyrone House, in Marlborough Street, the seat of the National Board, was the old residence of the Beresford family.

At the mouth of the Liffey stood an early Celtic settlement known as *Baile-ath-Cliath* (the 'town of the hurdleford'), and Whitworth Bridge now stands on the site of the ancient passage. The real foundation of the city was due to the Danes, and the name *Dubh-linn* ('black pool') was given to the dark stretch of water below the ford where the Viking ships lay. Here the Norsemen established a kingdom, and their power was not destroyed, notwithstanding the great battle of Clontarf (1014), until after the Anglo-Norman settlement. Henry II. came to Dublin in 1172, and granted to 'his men of Bristol' the city and its liberties by royal charter. The Castle was commenced early in the 13th century, and was defended by a city wall with many towers and gates, all surrounded by a moat fed by the Poddle River, which still finds its way, now underground, to the Liffey. Dublin suffered much at the hands of the wild septs of Wicklow, the O'Byrnes and the O'Tooles, who swept down from their mountain heights on the rich settlement in the plain, against whom a ring of castles and peel-towers was built for protection, the remains of many of which still stand. The terrible massacre of Easter ('Black') Monday, 1209, is perpetuated in the name Bloody Fields in the township of Rathmines. Edward Bruce besieged the city in 1316, and in 1486 Lambert Simnel was crowned in Christchurch. During the Civil War the city and surrounding country suffered at the hands of the contending parties; James II. held a parliament in Dublin in 1689, and Mass was celebrated in Christchurch. Down to the Restoration Dublin remained practically a medieval city; but after it a great change came in the expansion and trade of the city, especially under the viceroyalty of the Duke of Ormonde. In the 18th century the city became in features what it largely still is, with its great thoroughfares, stately public buildings, and extensive streets and squares of private residences, the names of which are chiefly identified with successive viceroys—so much so that its growth may be traced thereby. Memorable recent events

have been the great strike of 1913-14, under James Larkin, the Easter Rising of 1916, in the quelling of which much of Sackville Street, including the General Post-office, was ruined, the first meeting of Dáil Eireann at the Mansion House in 1919, the burning of the Custom House by republican irregulars in 1921, the seizure of the Four Courts and of Kilmainham Gaol by irregulars, and the blowing up of the former on surrender, the handing over of Dublin Castle, the Viceregal Lodge, and other buildings to the Irish authorities, the disbanding of the Royal Irish Constabulary, and the withdrawal of British troops in 1922.

See *History of the County Dublin*, by F. Elrington Ball; *History of Dublin*, by S. A. O. FitzPatrick; *The Story of Dublin*, by D. A. Chart; *The Book of Trinity College*; *History of Trinity College*, by W. Macneile Dixon.

Dubois, GUILLAUME (1656-1723), Cardinal, son of an apothecary, became tutor to the Duc de Chartres; and when the latter (now Duke of Orleans) became regent in 1715, was the most powerful man in France. In 1717 he succeeded in forming the Triple Alliance between England, Holland, and France, which, with the accession of the emperor in 1718, became the Quadruple Alliance. He was appointed foreign minister and Archbishop of Cambrai; in 1721 he became a cardinal, in 1722 prime-minister of France.

Du Bois-Reymond, EMIL, physiologist, was born in Berlin in 1818, and in 1841 began the researches in animal electricity with which his name is chiefly identified. The results of his labours in this field are contained in several valuable publications, the most important of which is his great work, *Untersuchungen über tierische Elektrizität* (Berlin, 2 vols. 1848-84). In 1858 he succeeded Joh. Müller in the chair of Physiology at Berlin, and in 1867 he was elected permanent secretary of the Academy of Sciences. Five volumes of his collected memoirs, addresses, and lectures appeared in 1885-99. He died 26th December 1896.

Dubovka, a town in the Russian province of Saratov, on the Volga, with tanneries and a large trade in mustard and salt; pop. 15,000.

Dubrovnik, Croatian name of Ragusa (q.v.).

Dubuque, a city and port of Iowa, on the right bank of the Mississippi, built partly on bluffs rising 200 feet above the river, which is here crossed by an iron railway bridge, 165 miles WNW. of Chicago. It is the seat of an Episcopal and of a Roman Catholic bishop, and contains numerous churches, a city hall, a custom-house of marble, and several colleges. It has a number of manufactures, and a large river and railway trade, and is the chief centre of the great lead and zinc region of the North-west. The town is the oldest in the state. Julien Dubuque, a French trader, engaged in lead-mining here as early as 1788; but the first permanent settlement was made in 1833. Pop. (1910) 38,484; (1920) 39,141.

Du Camp, MAXIME (1822-94), was born at Paris, made repeated journeys in the East, and settled in Paris. Besides works on his Eastern travels, he wrote poems, romances, *Souvenirs Littéraires*, a history of the Commune (*Les Convulsions de Paris*, 1879), and *Paris, ses Organes, ses Fonctions, et sa Vie* (6 vols. 1875; 7th ed. 1884). See his *Souvenirs Littéraires* (1882-83; Eng. trans. 1893).

Du Cange. CHARLES DUFRESNE, SIEUR DU CANGE, generally styled Ducange, one of the greatest of French scholars, was born at Amiens, 18th December 1610, and became a parliamentary advocate in Paris, where he died, 23d October 1688. There was scarcely any branch of science with which he was unacquainted, but his favourite studies

were classical philology and history. He wrote and edited several works on Byzantine and French history; but his principal productions are the *Glossarium ad Scriptores Medios et Infimos Latinitatis* (3 vols. folio, Paris, 1678; much enlarged by the Benedictines of St Maur, 6 vols. folio, Paris, 1733-36, to which four supplementary volumes were afterwards added by Carpentier, a Benedictine) and the *Glossarium ad Scriptores Medios et Infimos Græcitas* (Paris, 1688; new ed. Breslau, 1889-91), which are indispensable to the student of the middle ages. A new edition of the Latin Glossary was published by G. A. Henschel (7 vols. Paris, 1840-50), and final supplements were added by Diefenbach (Frankf. 1857 and 1867); a completely new edition in 10 volumes appeared in 1883-88. Du Cange left a large quantity of valuable manuscripts, which have been preserved.

Ducat, a gold coin, formerly in extensive use on the Continent, deriving its name, probably, from being issued (in 1140) by the Duke of Apulia; according to some, from *Dukas*, the family name of the Byzantine emperors Constantine X. and Michael. The Apulian coin bore the legend—*Sit tibi, Christe, datus, quem tu regis, iste Ducatus* ('Be this ducky, which thou rulest, dedicated to thee, O Christ'). Such coins were extensively issued after the 12th century in Italy, especially at Venice, where they were called *zecchini* or sequins (from *zecca*, 'a mint'). Early in the 14th century the ducat was introduced into Hungary and Bohemia; it was adopted in 1539 by the imperial diet of Germany into the currency of the empire, and was afterwards coined in the several German states, and over the whole of the north of the European continent, Russia included. The ducat varied in weight and fineness; by far the most common, which was current in Austria, Russia, Hamburg, &c., was worth about 9s. 4d. The modern Italian ducat was of much less value. There were silver ducats in Italy, worth 3s. 4d. sterling; and in Holland a *daalder* (4s. 2d.) was also called a ducat.

Ducato, CAPE (ancient *Leukati*), an abrupt headland at the south-west extremity of Leuka or Santa Maura, one of the Ionian Islands, dreaded by sailors for the fierce currents around it. On the summit are remains of a temple of Apollo, and from here criminals were anciently cast into the sea. Here, too, tradition fixes the scene of Sappho's fatal leap, and that of Artemisia (q.v.) of Halicarnassus.

Du Chaillu, PAUL BELLONI, a distinguished traveller, was born in Louisiana in July 1837, and went to school in Paris for a while. Ere he was twenty years old he was already noted as an African traveller, a series of letters on the Gaboon country which he contributed to the *New York Tribune*—a foretaste of the final fruits of his first great journey—having long ere his return from it excited much interest. In 1855 he sailed from New York to West Africa, where he spent four years in exploring the region two degrees on each side of the equator, making many interesting discoveries, and travelling about 8000 miles, always on foot, and unaccompanied by white men. He returned to New York in 1859, where he afterwards resided, and lectured frequently. The results of his African travels he published in his work, *Explorations and Adventures in Equatorial Africa* (1861; revised ed. 1871), containing very important contributions to geographical, ethnological, and zoological science. Thus he gave valuable information about the then unknown Ogowe (q.v.) River, and about the cannibal tribe of the Fanga. His contributions to zoology related mainly to the gorilla and other remarkable apes. He shot more than 2000 birds, 60 of which were

previously unknown, and killed over 1000 quadrupeds. Many of his specimens were purchased by the British Museum. The volume was, however, received with much distrust; and some critics asserted their belief that Du Chaillu's stories about the gorilla were entirely fabulous, and that he had never seen the animal alive, but had purchased his specimens. Du Chaillu's credit was, however, maintained by some men of the highest eminence, and particularly by Sir Roderick Murchison and Sir Richard Owen. The substantial accuracy of his statements was soon confirmed by a French expedition which explored the Ogowe River in 1862. In 1863-65 Du Chaillu revisited some of the scenes of his former explorations, vindicated the truthfulness of his former discoveries, and gave an account of his second expedition in *A Journey to Ashango-Land* (1867). He also published a series of books for the young, founded on his varied adventures, amongst which are *Stories of the Gorilla Country* (1868), *Wild Life under the Equator* (1869), *Lost in the Jungle* (1869), *My Aping Kingdom* (1870), and *The Country of the Dwarfs* (1871). His *Land of the Midnight Sun* (1881) is a record of a stay during 1872-78 in Norway and Sweden. *The Viking Age* appeared in 1889. He died 29th April 1903.

Duchesne, ANDRÉ (in Latin, Chesnius, Duchesnius, or Quercetanus), French historian, was born in Touraine in 1584, and died in 1640. History and geography were his favourite studies from his youth, and under Richelieu's ministry he was appointed royal geographer and historiographer. His most important works are the histories of England, Scotland, and Ireland, of the popes down to Paul V., and of the House of Burgundy, and his collections of the early Norman and French histories. His industry was extraordinary; he is said to have left more than a hundred folios in manuscript.

Duchesne, LOUIS MARIE OLIVIER, born in 1843 at St Servan, became in 1895 director of the French archaeological school at Rome, and in 1910 an academicien. An authority on early church history, he edited the *Liber Pontificalis* (1885-92), and wrote *Les premiers temps de l'état pontifical* (1898), *Origine du culte Chrétien* (new ed. 1905), *Histoire ancienne de l'église* (1906).

Duchesne, PÈRE. See HÉBERT.

Dučić, JOVAN, Serbian poet, born 1874, influenced by the French Parnassians and Symbolists.

Duck, any member of the family Anatidae, order Anseres (see GOOSE). Notable are the short webbed feet, with small hind-toe; the netted scales in front of the lower leg; the bill rounded at the tip, with nostrils towards the broad root. There are over fifty species, which have a wide distribution, especially in the northern hemisphere. They are characteristically aquatic birds, swimming with much agility, diving comparatively little, preferring to grub in the shallows for water-plants, worms, and small animals. The waddling, awkward walk is well known in its exaggerated condition in the domesticated duck. Great flocks are often seen in migratory flight to and from their northern homes. The males (drakes) are in winter and spring markedly distinguished from the females, whose plumage is less handsome. In summer, however, the males generally resemble the females.

The most important genus is *Anas*, which includes the Common Wild Duck (*A. boschas*), with its domesticated form (*A. domestica*), and numerous other species. The Mallard or Wild Duck is very widely distributed from Britain to Japan, and also occurs in North America as far south as Florida and the West Indies. Mallards abound in Britain, though ousted from some parts by increased drainage of marshes. Their food is very varied, from seeds and

roots to worms and frogs. They are often seen, with submerged head and upturned tail, grubbing in the mud by the loch side. Along with other 'wild ducks,' they breed in Britain, sometimes near the lakes or rivers which they frequent, sometimes in more elevated moorland districts. The parents often bring their very young brood to the lower waters, by swimming down the streams when swollen by rain, and it is interesting to see the little creatures hurried on, without injury, by the current, and passing along narrow rapids and over waterfalls of considerable height, much as pieces of cork might do, and with as little apparent injury. The nest is composed of grass, intermixed and lined with down, and the eggs are usually nine to twelve in number. The female shows marked parental care and affection for her brood.

The male (drake) of the common duck has the four middle tail-feathers recurved. The deep emerald green of the head and upper part of the neck, the white collar which separates the green from the dark chestnut of the lower part of the neck, and the deep blue iridescent *speculum* of the wing are marked characteristics of this beautiful bird. The plumage exhibits greater brightness of colours in the wild than in the domestic variety. At the close of the breeding season, the male of the wild duck assumes for a time a plumage more sober, and resembling that of the female; but before winter recovers the splendid plumage proper to his sex.

The Domestic Duck.—According to Darwin and most naturalists, the various breeds of domestic duck are all descended from the wild species above described. In domestication the excellence of the plumage and the elegance of the carriage are lost in a few generations, and more momentous changes follow in consequence of altered nutrition and the like, and largely from the decreased use of the wings and increased use of the legs. The size also increases. It is well known that the nest-building instinct has been unlearned, and even the brooding impulses are usually degenerate. Darwin distinguishes four breeds: the Common Domestic Duck, the Hook-billed Duck, the Call-duck, and the Penguin Duck. Of the first, several sub-breeds are well known—e.g. the Aylesbury—large and white; the Rouen—large, and coloured like the wild duck; the tufted ducks—with top-knots of downy feathers; the black Labradors. 'The duck was unknown to the ancient Egyptians, to the Jews of the Old Testament, and to the Greeks of the Homeric period,' but was kept eighteen centuries ago in Roman poultry-yards. See Darwin's *Variation of Animals and Plants under Domestication* (1868). For ducks as egg-producers, see POULTRY.

There are many other European wild ducks—e.g. the small *A. crecca*, extending to North Africa; *A. acuta*, also found in North America; *A. strepera*, a distinctly north European form; *A. querquedula*, from middle and south Europe to Central Asia; *A. penelope*, in north Europe and Asia. Some closely related genera may be noted. The beautiful North American *Aix sponsa* is often brought to Europe; the Spoon-billed Ducks (*Spatula clypeata*, &c.), occurring in the temperate zones of both hemispheres, have markedly elongated bills; the Musk-duck (*Cairna moschata*), from Brazil and Paraguay, sometimes domesticated, is remarkable for the musk-like smell of the male preen-gland. Less nearly related to the true ducks are the Geese (see GOOSE), Swans (q.v.), Eiders (q.v.), and the stiff-tailed ducks, such as the wide-headed *Eristambura buccocephala*, rather like a diver in flight and habit.

Many wild ducks are shot for the market; the plumage is also used for decorative purposes. The uses of the domesticated variety are well known. See also TEAL, CANVAS-BACK, WILDEWING.

Duck (akin to Ger. *tuch*, 'cloth'), a coarse cloth or canvas, highly glazed, used for sails, sacking, smock-frocks, overalls, trousers, &c.

Duckbill, or **DUCKMOLE**. See ORNITHORHYNCHUS.

Ducking-stool, an apparatus at one time in use in England for the punishment of scolding wives. The *cucking-stool*, *ducking-stool*, and *tumbrel* have often been confounded, and indeed most writers appear to consider them but different names for the same thing, but, as Mr Llewellynn Jewitt points out, they are all three distinct varieties of punishment. The cucking-stool is mentioned in Domesday Book as having been in use in Chester, and the name (*cathedra stercoris*) casts a light upon the degrading nature of its origin. In it the culprit, who might be of either sex, was placed, usually before his own door, to be pelted and insulted by the mob. On the tumbrel again he was drawn round the town or village, seated in the chair, which was sometimes so constructed as to be suitable also for ducking; but the ducking-stool *par excellence* was specially made for purposes of immersion. There were various examples of the ducking-stool. Sometimes it consisted of a rough strong chair attached to one end of a beam, which worked on a pivot on a post bedded into the ground at the edge of the dam, or the river, as the case might be. The woman was fixed in the chair with her arms drawn downwards. The executors of the punishment then took hold of a chain at the opposite end, and gave her a ducking on the 'see-saw' principle. Many ducking-stools and chairs are still in existence; that at Leominster was used as recently as 1809. The practice of ducking commenced in the latter part of the 15th century, and prevailed generally throughout the kingdom until the first part of the 18th century, and in isolated cases, as we have seen, even into the 19th century. See Llewellynn Jewitt in the *Reliquary* (vol. i. 1860); W. Andrews, *Old Time Punishments* (1890).

Duckweed, or **DUCK-WEED** (*Lemna*), is the type of Lemnaceæ, a small order of very degenerate monocotyledons, probably allied to Araceæ. They are chiefly floating plants, mere flat green fronds, with roots hanging loosely in the water, and unisexual flowers—destitute of calyx and corolla—bursting through a membranous spathe in their margin. The Lemnaceæ are distributed throughout all parts of the world. Several species of duckweed are British, and cover the surface of stagnant ponds with green vegetation. Their flowers and fruits are rarely to be seen, but they spread rapidly by budding from their margins.

Duclaux, MME. See DARMESTETER.

Ducrow, ANDREW (1793-1842), the 'Colossus of Equestrians,' was born at Southwark, the son of a Belgian 'strong man.' He toured France successfully with his brothers and sisters; and having in 1825 become joint-proprietor of Astley's, left a large fortune, although the burning of his theatre (1841) unbinged his mind and caused his death.

Ductility is that property of solids in virtue of which they can be drawn out so as to increase their length at the expense of their cross dimensions. Thus silver is a very ductile metal, while platinum is not so ductile. But although platinum cannot be drawn out to any very great extent by the ordinary process of wire-drawing, it may be drawn out by Wollaston's process. Wollaston fitted a platinum wire into the interior of a hollow rod of silver, and then drew out the compound rod to an extent limited only by the ductility of silver. He then dissolved off the silver, and so obtained an excessively fine platinum wire, the diameter of which was, according to Leslie, $\frac{1}{1000}$ inch. Leslie also says that, by drawing out a thickly-gilt silver

rod, a film of gold only $\frac{1}{100000}$ inch in diameter could be obtained. See MALLEABILITY, WIRE.

Ductless Glands. See GLANDS, and separate articles, THYROID, &c.

Du Deffand. See DEFFAND.

Dudevant, MADAME. See SAND (GEORGE).

Dudley, a municipal, county, and parliamentary borough in a part of Worcestershire embedded in the south of Staffordshire, $8\frac{1}{2}$ miles WNW. of Birmingham. Situated in the heart of the 'Black Country,' it is a thriving town with coal-mining, busy brass and iron foundries, brickworks, besides tanning and brewing. The iron industries include the making of bedsteads, fenders, vices, and anvils. A chief ornament of the place is the Renaissance drinking-fountain, erected in 1867 by the Earl of Dudley, a statue of whom was erected in 1888. On a hill to the north-east are the beautiful ruins of an old castle, said to have been founded in the 8th century by Dodo, a Saxon prince, the keep of which dates from the 13th century. It was burned in 1750. Near it are remains of a Cluniac priory (1161). The vicinity yields abundant limestone (see below); it is wrought out of caverns, and brought to the kilns through a tunnel one mile and three-quarters long, which is carried through the basalt of the Castle Hill. Pop. of municipal borough (1891) 45,724; (1911) 51,979; (1921) 55,908. Dudley has returned one member since 1832; the municipal borough dates from 1865.

Dudley Limestone is a highly fossiliferous Silurian limestone belonging to the Wenlock Series (q.v.), which forms some of the most picturesque eminences around the town of Dudley. The masses of corals, shells, and trilobites which abound in this rock, form, when weathered, extremely beautiful cabinet specimens.—*Dudley Locust* is the popular name for a trilobite (*Calymene Blumenbachii*), which is very abundant in the Dudley limestone.

Dudley, EDMUND (1462?-1510), lawyer and privy-councillor, was Empson's partner in carrying out the detested policy of Henry VII., whose son and successor sent him to the block. He was father of the Duke of Northumberland. See PERCY, GREY (LADY JANE), and LEICESTER.

Duelling. The duello (from the Lat. *duellum*, an old form of *bellum*) belongs to every age and country, uncivilised as well as civilised. The old 'ordeal by battle,' a sort of judicial decision, implied that the Almighty would give victory to the just cause, and was in vogue in England down to the reign of Elizabeth (see BATTLE, WAIVER OF). Neither this nor the chance quarrel of two gentlemen carrying swords can be strictly considered a duel, which implies deliberation. The modern duel is prompted by the worst passions, hatred, revenge, jealousy, and often by the merest trifle. In France, where it has long flourished, it was punished severely by kings and parliaments, and Henry II., Henry IV., and Louis XIV. took stringent measures to put duelling down. Francis I., however, was in its favour, and even challenged Charles V. to single combat. It is said that during the earlier years of Henry IV.'s reign no less than 4000 gentlemen lost their lives in this way. In Louis XIV.'s day, duels of four and five a side were common, but his edict of 1679 completely suppressed it.

It is remarkable that at this moment there is but one group of countries—viz. the English-speaking lands—where duelling is not merely scouted and put down by law, but actually ridiculed. This cannot be explained by English respect for the law, or from a strict religious sense; both these feelings being as strong when duelling was in high fashion. In the reign of William III. a severe act against it was passed, and in 1712 it again engaged the attention of the parliament.

Duels with the pistol prevailed in England for nearly a century; to within living memory, ministers and politicians resorted freely to this mode of settling a quarrel. Wilkes met Lord Talbot, and also Mr Martin, in 1763, by whom he was severely wounded. Mr Pitt was challenged by Mr Tierney for charging him with 'obstructing the defences of the country.' The day fixed for the encounter was a Sunday of May 1796, and at three o'clock the parties were found on Putney Heath, close to the Kingston Road. The duellists fired twice at each other; but on the second occasion Pitt discharged his pistol in the air. Pitt's great rival, Charles Fox, had been particularly severe on the powder supplied by the War Office. Mr Adam took offence at this charge, and challenged him. The parties met, and Fox was wounded. The buoyant humour of the man, which made him so many friends, was shown in his first remark, 'Adam, you'd have killed me if you hadn't used government powder.'

Another political duel took place in September 1809, between Mr Canning and Lord Castlereagh (q.v.); a yet more remarkable duel was that of the Duke of Wellington with Lord Winchilsea in the exciting year 1829. Lord Winchilsea charged the duke with the 'insidious design of introducing Popery.' The duke at once sent Sir Henry Hardinge to demand an apology. The meeting was at Battersea Fields. Lord Winchilsea was attended by Lord Falmouth, a second so completely unnerved that he had to be assisted in loading his pistols. The duke was gay and unconcerned. When their men were placed, the duke's second advanced with a paper in his hand. 'As for myself,' said he, 'if I do not express my open disgust for the whole affair, it is because I wish to imitate the moderation of the Duke of Wellington.' Lord Winchilsea was quite overwhelmed by this irregular lecture, his second faltered out that 'nothing had ever given him so much pain,' &c. To whom Sir Henry: 'Indeed, my lord, I don't envy your feelings.' A crowd had collected to see the sport. The duke hesitated a little and fired; Lord Winchilsea then fired in the air. Lord Falmouth now came forward with a paper. The duke, who had drawn near to listen, said in a low voice, 'This won't do: it is no apology.' Sir Henry pulled out his paper, and reading it, said: 'This is what we require; the word apology must be used.' At last the required word was furnished. Then Sir Henry gave the guilty pair a last rebuke. 'And now, gentlemen,' he said, 'without making any invidious reflections, I cannot help remarking that, whether wisely or unwisely the world will judge, you have been the cause of bringing this man into the field, where, during the whole course of a long military career, he never was before.' Here Lord Falmouth turned on his unhappy principal to tell him that 'he always thought, and had told him so, that he was completely in the wrong.' Lord Falmouth then attempted to vindicate himself. 'My Lord Falmouth,' was the duke's haughty reply, 'I have nothing to do with these matters.' He then touched his hat with two fingers, saying: 'Good morning, my Lord Winchilsea; good morning, my Lord Falmouth,' and rode away. It is remarkable that most of these fire-eating politicians—viz. Wellington, Castlereagh, Canning, Tierney—were of Irish extraction.

There have been three notable duels, each attended with fatal issue, and each arising out of a political quarrel. One was that of Mr Scott, editor of the *Champion*, killed by Mr Christie in 1821; the second was that of Sir A. Boswell in 1822, killed by Mr James Stuart of Dunearn, the quarrel arising out of a foolish ballad written by the former; the third was the well-known fatal en-

counter of Mr O'Connell with D'Esterre, in which the latter fell. Another fatal duel was that of Lord Camelford and Mr Best in 1804. In Ireland, before and after the union, there was a mania for duelling; and personages of the highest position, lord chancellors, judges, provosts, and all fought, or as the phrase went, 'blazed.' Of modern duels the most notable was that of Lord Cardigan with Captain Harvey Tuckett, in which the latter was wounded (1840). Up to 1843 duelling was almost recognised as an obligation, but in that year it received its *quinetus*, owing to the fatal contest between Colonel Fawcett and Lieutenant Munro, his brother-in-law, in which the former was killed. Thereafter only one fatal duel was fought by Englishmen in England, between Lieutenants Hawkey and Seton, in May 1845, when the latter was killed. The last duel in Ireland (February 1851), between the mayor of Sligo and a lawyer, was a bloodless one.

In most countries, as we have said, duelling is still resorted to as reparation for personal insult or injury. In France, fencing is studied, as a necessary part of education and protection, by most public men and journalists. The encounters are generally harmless, and often *pour rire*. Two modern political duels excited the merriment of Europe, that of Gambetta and M. Fourtoun, who 'fought' in a foggy morning at thirty or forty paces distance (1878), and that of General Boulanger, who spitted himself on the rapier of a retired attorney, M. Floquet, then first minister (1888). Perhaps the most notable political duel was that of Armand Carrel with Émile de Girardin (1836), when the former fell mortally wounded. In France, two seconds on each side regulate the proceedings, and one stands beside the combatants, ready with a walking-stick to beat down the weapons in case of unfair fighting. This precaution is not unnecessary, as one of the parties has been known to seize his adversary's sword with one hand, and try to 'finish' him. In Belgium the duel occurs seldom, though still enforced by social law, but the country is often selected by Frenchmen and others as the *terrain* of their encounters.

In other countries duels are comparatively rare. In the United States, where they were at one time fought with a savage ferocity and originality combined (in some sections, with bowie-knives), they are now practically unknown, save in the very backward states. None has been more famous than one of the earliest, in 1804, when Aaron Burr, the vice-president, killed Alexander Hamilton, the leader of the opposition. Later duels were those between Henry Clay and John Randolph, Andrew Jackson and Charles Dickinson, Thomas H. Benton and Lucas. By the common law, the survivor and the seconds are guilty of murder when one of the parties to a duel is killed.

The question of insult, the form of reparation, withdrawals, &c., led naturally to some complication, and there have been attempts to draw up rules and regulations. Towards the end of the 18th century, a number of duelling gentlemen ('delegates') met at Clonmel, and drew up a 'code,' conceived in a highly logical spirit. One specimen will suffice: 'Where the *lie direct* is the first offence, the aggressor must exchange two shots previous to apology, or three shots followed by explanation, or *fire on* until one is hit. The only satisfaction for a blow is to offer a cane which is to be laid on the offender's shoulders. If a blow be an answer to giving the lie, the lie is merged in the blow, which becomes the sole offence,' &c. There are so-called duels, in which lots are cast, and the party to whom the lot falls is bound to put an end to his own life. There have been cases of duels with sword and pistol between women.

By the laws of the German empire, duelling was an offence punishable with fortress-imprisonment, the length of which was proportioned to the nature and consequences of the encounter. Students' duels, so-called, really a form of sport (*Mensur*), ranging in seriousness from mere fencing matches to dangerous or even fatal encounters, were formerly treated as mere 'disciplinary offences,' unless the consequences were very serious. But public feeling turned against them; and from 1883 the imperial courts imposed fortress-imprisonment. In contradiction to the spirit of the public laws, duelling continued to be recognised in the German army, whence an officer was expelled in 1887 for refusing to challenge one who had insulted him. The Emperor William I., pious as he was, felt constrained to draw up regulations on the subject, introducing courts of honour, which, however, in serious cases, might authorise the encounter. These were abolished by the republican constitution. In 1844 the English War Office, moved thereto by Prince Albert, put a summary stop to the practice—issuing a number of regulations which threatened all concerned in a duel with court-martial and cashiering. For the law of the land makes no distinction between any of the methods of taking another's life, though the old attitude of the law to affairs of honour was fairly expressed by an Irish judge, who, when charging in a fatal case, declared that it was his duty to tell the jury that it was murder according to the law, 'but that for his part a fairer duel he had never met in his life.' In a work revised by him in 1853, Lord Cockburn similarly expressed his opinion that 'murder may be committed in duel required by society, and provoked by intolerable insult.'

See Dr Millingen, *History of Duelling* (2 vols. 1841); A. Steinmetz, *The Romance of Duelling* (2 vols. 1868); Rodenbeck, *Der Zweikampf* (1883); Constand de Massi, *Duelling in all Countries* (trans. 1880); William Douglas, *Duelling Days in the Army* (1887); Alfred Hutton, *The Sword and the Centuries* (1901); Edou. *L'Escrime et le Duel* (1908); and Thimm's bibliography (1896).

Duet, a composition in music for two voices or instrumental performers.

Duff, ALEXANDER, a great Indian missionary, was born 26th April 1806, at a farm near Pitlochry, in Perthshire. When a student at St Andrews his character was powerfully influenced by Chalmers, and in 1829 he was ordained the first missionary from the Church of Scotland to India. On the passage out he was twice shipwrecked, and he did not reach Calcutta till May 1830. He began his work as a missionary on an entirely new plan, freely opening up Western science and learning to the natives of India as well as purely religious teaching—an innovation that marked the beginning of a real era in the social history of that country. In spite of much misapprehension and not a little violent opposition, his English school flourished, and in the course of time its indomitable promoter was cheered by the warm encouragement of some of the highest personages in the government. In 1834 Duff was obliged to return home, already invalided by his enthusiastic and restless energy; but he returned in 1840 to find his college maintaining its success, with an attendance of between six and seven hundred pupils. At the Disruption within the Church of Scotland in 1843, Duff, with the other missionaries in India, cast in his lot with the seceding body that formed the Free Church, and of course had in consequence to give his college into other hands, and begin his work again from the beginning. But for this the enormous energy of the man was adequate, and ere long his whole educational and missionary work was completely reorganised, and that on a much ampler scale than before. In 1844 Duff helped to start the *Calcutta Review*, and in 1849 was again

obliged by ill-health to return home, traversing India on the journey. He was moderator of the Free Church General Assembly in 1851. In 1856 Duff returned to India, and guided his mission safely through the troublous time of the Mutiny. He was one of the founders of the university of Calcutta, but in 1863 was obliged by persistent ill-health to leave India permanently. In Scotland he laboured much to infuse missionary zeal throughout the community; he raised £10,000 to endow a missionary chair in the New College, Edinburgh, of which he agreed to be the first occupier. In 1873, to avert a threatening crisis within the Free Church, he was called a second time to the moderator's chair. He died in Edinburgh, 12th February 1878.

See his *Life* by Dr George Smith (2 vols. 1879; new ed. 1899), and a short *Life* by Prof. Thomas Smith (1883).

Duff, SIR MOUNTSTUART ELPHINSTONE GRANT (1829-1906), born at Eden in Aberdeenshire, son of James Grant Duff (1789-1858; historian of the Marhattas), was educated at Edinburgh and Balliol, and called to the bar. In 1857-81 he was (Liberal) M.P. for the Elgin Burghs, and delivered notable surveys of foreign politics to his constituents in the famous 'Elgin Speeches.' Successively Under-secretary for the Colonies and for India, he was in 1881-86 governor of Madras, and was made G.C.S.I. He wrote *Lives of Sir Henry Main*, *Roman*, and *Lord de Tabley*, *Notes of an Indian Journey*, and *Miscellanies, Literary and Critical*; but is best remembered for the fourteen volumes of his *Notes from a Diary* (1897-1905), which illustrate his exceptional all-round culture—classics, botany, archaeology, religion, poetry, and the personal gossip of his time.

Dufferin and Ava, FREDERICK TEMPLE HAMILTON TEMPLE BLACKWOOD, MARQUESS OF, G.C.B., G.C.M.G., the son of the fourth Baron Dufferin, was born at Florence on June 21, 1826, and succeeded to the peerage in 1841. Educated at Eton and Christ Church, Oxford, he first distinguished himself by contributions to literature, and published the popular *Letters from High Latitudes* in 1859. In 1860 he was sent by Lord Palmerston to Syria, to investigate the questions arising from the religious massacres, and on his return was created K.C.B. Lord Dufferin was successively Under-secretary for India (1864-66), and for War (1866). He was Chancellor of the Duchy of Lancaster from 1868 to 1872; in 1871 was created an earl; and was Governor-general of Canada (1872-78). His brilliant administration was remarkable for the wonderful development of the province of Manitoba. From 1879 to 1881 Lord Dufferin was ambassador at St Petersburg, whence he was transferred to Constantinople. After the collapse of Arabi's rebellion, Lord Dufferin went to Cairo to restore order in Egypt. To him was due the abolition of the Dual Control. In 1884 he succeeded Lord Ripon as Viceroy of India. His tenure of office was made memorable by measures for strengthening the Indian frontier; by the various attempts to delimit the Afghan frontier, which, though interrupted by the Russian attack on Penjdeh, were brought to a successful issue by the Anglo-Russian commission; and, above all, by the annexation of Upper Burma in Dec. 1885. That province had been reduced to submission, and the Tibetans had been defeated by the Sikkim expulsions, when Lord Dufferin resigned in 1888. He became ambassador at Rome, marquis (1888), and ambassador to France (1891-96), and died 12th February 1902. See his *Life* by Sir Alfred Lyall (1905).—His mother, Helen Selina Sheridan (1807-87), was the author of 'The Irish Emigrant,' 'The Bay of Dublin,' and other songs; see *Memoir* by her son prefixed to her *Songs, Poems, and Verses* (1894).

Duff-Gordon. See GORDON.

Duffy, SIR CHARLES GAVAN (1816-1903), Irish patriot, was born in County Monaghan, and early devoted himself to journalism in Dublin and Belfast, returning to the former in 1842 to start along with Thomas Davis and John Dillon the famous *Nation* newspaper, as the organ of the Young Ireland party. Tried and convicted for sedition with O'Connell in 1844, but saved by the House of Lords quashing the conviction, he aided his great chief in the agitation for repeal, next helped him to found the Irish Confederation, and gave his heartiest sympathy to the patriotic dreams of Smith O'Brien. Again tried in 1848 for 'treason-felony,' he was acquitted, next revived the *Nation*, and carried in 1852 the borough of New Ross in the teeth of the Under-secretary for Ireland. He had an active share in promoting the Tenant League and the Independent Irish party, and on the break up of the latter, emigrated to Australia in 1856. After some time of practice at the Melbourne bar, he drifted into politics, and after the establishment of the Victorian constitution, rose in 1857 to be Minister of Public Works, of Lands in 1858 and 1862, and prime-minister in 1871. He was defeated next year, was knighted in 1873, and in 1877 elected Speaker of the Legislative Assembly. His little work, *The Ballad Poetry of Ireland*, had been for thirty years a household book in his native country, when in 1880 he published his striking *Young Ireland, 1840-50*, followed in 1883 by *Four Years of Irish History, 1845-49*. See the autobiographical *My Life in Two Hemispheres* (1898).

Dufresne, CHARLES. See DU CANGE.

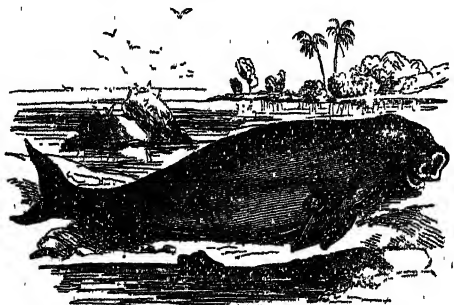

Dugdale, SIR WILLIAM, antiquary, was born at Shustoke, near Coleshill, Warwickshire, 12th September 1605. He spent more than four years at Coventry free school, and then studied law and history under his father, to please whom, aged and palsied, he married before he was eighteen, and soon after whose death he purchased the neighbouring manor of Blythe (1625). Inspired with the notion of writing a history of Warwickshire, he came in 1635 to London, where, making the acquaintance of Spelman and other antiquaries, in 1638 he was created a pursuivant-at-arms extraordinary, with the title of Blanch Lyon, and in 1640 Rouge Croix pursuivant. During the Great Rebellion he adhered to the royalist cause, and from 1642 to 1646 was at Oxford, the king's headquarters, being made an M.A. and Chester herald, while pursuing his antiquarian researches. 'All the while that the power of the usurpers continued he was compelled to live depressed in a very low estate; but, as the darkest night hath its morning, so,' on the Restoration Clarendon got him the office of Norroy. In 1677 he was promoted to be Garter Principal King of Arms, at the same time receiving the honour of knighthood, 'much against his will, by reason of his small estate.' Evelyn describes him in 1685 as 'having his sight and his memory perfect;' but on 10th February 1686 he died in his chair at Blythe Hall. The *Monasticon Anglicanum* (3 vols. 1655-61-73), a history of English religious foundations, with their charters, &c., though planned and in part compiled by another antiquary, Roger Dodsworth (1585-1654), was concluded, arranged, indexed, and revised by Dugdale; there is a noble English edition of it by Bandinel, Caley, and Sir Henry Ellis (6 vols. 1817-30). The *Antiquities of Warwickshire* (1656; 3d ed. 1763-65) has been the model of every subsequent county history; of Dugdale's nine other works the chief are the *History of St Paul's Cathedral* (1658), *History of Imbanking and Drayning* (1662), *Origines Juridicales* (1666), and *Baronage of England* (3 vols. 1675-76). In Anthony & Wood's words, 'What Dugdale hath done

is prodigious. His memory ought to be venerated and had in everlasting remembrance.' See his *Life, Diary, and Correspondence*, ed. Hauser (1827).

Dugi. See ISOLA GROSSA.

Dugong (*Halicore*), a genus of marine mammals in the order Sirenia. Along with the manatees, the dugongs exhibit the following general characteristics. The form of the body is fish-like, but somewhat depressed; the head is rounded, distinct, and not out of proportion to the body; there is hardly any neck; the tail is horizontally flattened; there are no hind-limbs, nor is there a dorsal fin. In relation to the aquatic habit, the fore-limbs are paddle-shaped flippers, the skin is almost hairless except about the mouth, there are no external ears, and the nostrils have valves. The very small eyes, with imperfect lids, have a nictitating membrane, which is absent in Cetaceans. The nostrils are at the end of the snout. The lips are thick and bristly. The bones of the skeleton are very massive and heavy, a condition which, as Sir William Flower notes, must help these animals to keep to the bottom while feeding on algae. The skull is in many ways peculiar, but is not like that of Cetaceans. The usual separate terminal ossifications or epiphyses on the vertebrae are absent; so too are the clavicles; there is no fused sacrum, and a most rudimentary hip-girdle, without trace of hind-limbs. There are no canine teeth. The brain is relatively small, with few convolutions. The tongue is small, fixed, and very rough. The stomach is chambered; the long muscular intestine is provided with a caecum. The two ventricles of the heart are partly separated by a deep cleft, and the arteries form complex networks (*retia mirabilia*), which may aid the animals when under water. The larynx is not modified as in Cetaceans. The lungs are very long and narrow, and the diaphragm is very oblique. The teats are two in number, behind the arm-pits. The placenta is diffuse. The animals are sluggish, herbivorous, inoffensive, and gregarious. *Halicore* and *Manatus* are the only living genera; *Rhytina* is recently extinct; *Halitherium* is an important fossil form referable to this now moribund but once flourishing order.

The dugong differs in many important respects from the manatee. A few of its numerous peculiarities must be noticed. The upper jaw is very massive and turned sharply downwards, overlapping the lower, which is also crooked. The males possess two tusk-like projecting incisors, but the corresponding teeth abort in the females. The front-teeth of the lower jaw abort, and are absorbed. The jaws both bear rough horny plates. There are five to six molar teeth of a primitive sort, with

Dugong (*Halicore dugong*).

persisting pulps and no enamel. Only two or three are in use at a time. The dark, elephant-like, tough skin bears short sparse bristles. The tail is deeply notched. The fingers are nailless. The

œcum is thick and simple. Of the three species of Halicore, one (*H. tabernaculi*) is restricted to the East African coast and the Red Sea; another (*H. dugong*) inhabits the Indian and Pacific oceans, eastward from the home of the last to the Philippines; and the third (*H. australis*), the waters of Eastern and Northern Australia.

The dugongs keep to the water, rising to the surface to breathe. They never venture ashore, but graze at the bottom in shallow water. Their food consists chiefly of seaweeds, which they gather in with their thick lips. They are sociable but stupid, often to their own undoing. They are known to attain a length of about 10 feet, but larger sizes are alleged. The habit the dugong has of lifting its round head out of the water, and of carrying its baby under its arm, is suggested as a possible foundation for the mermaid myth, which the name of the order (Sirenia) recalls. Their peculiar, feeble cry may also have aided the imagination of early observers. The female bears one young one at a time, and exhibits an affection said to be proverbial. When the young one is speared, the mother is readily taken. The flesh of the dugong is eaten and esteemed, especially when young. The Australian species is killed for the sake of its oil, which is free from disagreeable smell, and said to have the medicinal qualities of the cod-liver equivalent. According to Ruppell, it was with the skin of the Red Sea dugong (not 'badger-skins,' as in A.V.) that the Jews were directed to veil the tabernacle.

Cuvier called the Sirenia herbivorous Cetaceans, De Blainville emphasised their connection with elephant types, and some modern zoologists maintain their affinity with Ungulates. No conclusion is yet possible, except that they have no direct connection with Cetaceans. Even the fossil forms, Flower observes, have not in this case helped much towards solving the riddle of Sirenian affinities. All that can be certainly said is that the order is at once peculiar and primitive.

See MANATEE, RHYTTINA; J. F. Brandt, *Symbolæ Sireniologice* (St Petersburg, 1846-68); Huxley's *Anatomy of the Vertebrates*; Flower's *Osteology of the Mammalia*, &c.

Duguay-Trouin, RENÉ, one of the most celebrated naval officers of France, was born 10th June 1673, at St Malo. From 1689 to 1697 he cruised about as a sort of privateer, inflicting immense damage on the enemies of France. Louis XIV., as a reward for his daring exploits, admitted him into the state navy, and gave him the command of a frigate. In 1707 he engaged a part of the English fleet at the entrance of the Channel, burned one ship, captured three others, and about sixty transports; but the most glorious of his triumphs was the attack and capture of Rio Janeiro in 1711, with a small fleet, after hostilities had lasted for eleven days. The city was ransomed for 610,000 crusados (£96,000). For this he was ennobled, and was successively named *chef d'escadre*, member of the council of state, lieutenant-general, and naval commandant at Brest. In 1731 he was sent into the Levant, to obtain reparation for the damages done to French commerce. He died 27th September 1736. See his *Mémoires* by Beauchamps (4 vols. Paris, 1740; Eng. trans. 1742), and Life by La Landelle (2d ed. 1876).

Du Guesclin. See GUESCLIN.

Duiker. See BUSH ANTELOPE.

Duisburg, a town of Rheinland, 16 miles N. of Düsseldorf by rail, in a fertile district between the Ruhr and the Rhine, with both of which it is connected by a canal. St Salvator's church dates from the 15th century. In and near the place are great ironworks and coal-mines. There is very extensive river shipping and shipbuilding, the

Duisburg-Ruhrort harbour being exceptionally large for an inland place. Manufactures include bridges, boilers, machinery, rolling-stock, enamel, copper goods, pulleys, cranes, bricks, beer and spirits, besides corn-mills and saw-mills. Pop. (1816) 4508; (1885) 47,561; (1910) 229,483; (1919) 244,302, nearly half Protestants. Duisburg is an ancient town. In the 13th century it was a member of the Hanseatic League, and afterwards a free town of the German empire, but at the close of the war in 1815 it became finally Prussian. French occupation (from 1921) was a heavy blow.

Dujardin, FÉLIX (1801-60), born at Tours, was professor of Zoology at Rennes, is notable for his study of Foraminifera and of Protozoa (q.v.).

Dukas, PAUL, French composer, born in Paris, 1st October 1865, studied at the Conservatoire, where he afterwards became a professor. Best known in Britain by his symphonic piece *L'Apprenti Sorcier*, he composed also the opera *Ariane et Barbe Bleue* and other works, and wrote music criticism.

Duke (Fr. *duc*, Lat. *dux*, from *ducere*, 'to lead'), a term applied originally to any military leader. The title came first into formal use when Constantine separated the civil and the military commands in the provinces. From that time forth, the military governors of provinces were either counts or dukes. But these titles originally stood to each other in an opposite relation to that which they afterwards assumed. 'All provincial generals,' according to Gibbon, 'were *dukes*, but no more than ten among them were dignified with the rank of counts, or companions, a title of honour, or rather of favour, which had been recently invented in the court of Constantine.' See COUNT. Both were strictly prohibited from interfering in any matter which related to the administration of justice or the revenue. When the Germanic barbarians invaded the provinces of the empire, the military chiefs of their tribes (called by names cognate with *heretog* or *herzog*) were sometimes identified with the *duces*; but amongst the Franks and Longobards, the functions of the so-called *dux* were rather those of the old German *Graf* (Lat. *Comes*; see COUNT). By-and-by the ordinary count became the lieutenant of the duke, and the government of the latter extended to several provinces; whereas that of the former was confined to one province, or even to a single locality. The power of the dukes grew so rapidly, in consequence of the dissensions of the Merovingians, that, towards the end of the 6th century, they arrogated to themselves the right to dispose of the crown. In the 10th century, the East Frankish empire fell into the five hereditary dukedoms of Franconia, Swabia, Bavaria, Saxony, and Lorraine. In the west, the dukes of the Isle of France, Aquitaine, Burgundy, Normandy, Gascony, and others assumed the crown and sceptre, promulgated laws for their subjects, struck money with their own image, and made war in their own name against the crown. The confederation of the feudal lords had assumed such dimensions, that about the period of the Norman invasion of England nothing remained directly under the crown except a few towns, of which Reims and Laon were the chief. The rest of the kingdom was divided amongst the dukes and the counts, under an obligation, which they almost always evaded, of service and fidelity to the crown. But by 1514 these regal duchies had been either extinguished or reunited to the crown.

The duchies which were granted to members of the royal family—that of Bourbon, erected in 1327; of Orleans, in 1344; of Auvergne, Berry, Touraine, Valois, and Alençon at later periods

—enjoyed none of the privileges of independent sovereignty which had belonged to the ancient duchies; and when the Montmorencies were created dukes in 1551, they enjoyed no other privileges than those of titled nobles. The duke-peers, as they were called, were simply the first class of nobles in France, just as dukes are in England. Several prelates enjoyed this rank—as, for example, the Archbishop-duke of Reims. There were also in France dukes for life, or patent dukes, who dated only from the reign of Louis XIV. Swept away by the Revolution, the title was restored by Napoleon, who conferred it, with rich endowments, on his marshals. Several ducal peers were created by Louis XVIII. and Charles X. In Germany, the dukedom passed through phases very similar to those which it exhibited in the earlier history of France. The title of grand-duke was first bestowed on Cosmo de' Medici, Grand-duke of Tuscany, by Pope Pius V. in 1569; it was assumed by the princes of the imperial family of Russia, and was used by certain German reigning princes. Arch-duke (q.v.) was Austrian only.

William the Conqueror, Duke of Normandy, may be held to have brought the title as a separate dignity into England; but it was merged in the crown until the reign of Edward III., who, in 1337, conferred the dukedom of Cornwall on the Black Prince, his eldest son, and in 1351 that of Lancaster on Henry Plantagenet, his cousin. These were dukedoms by tenure, Cornwall (q.v.) being in the one case erected into a duchy, and palatine jurisdiction being in the other conferred within the county of Lancaster. In later cases the dignity of duke was personal, and unaccompanied with grants of lands and annuities. In 1362 Edward III. conferred the dukedom of Clarence on Lionel, his third son, and the dukedom of Lancaster on John of Gaunt, his fourth son and husband of the then heiress of the former Duke of Lancaster. Two other sons of Edward III. were in 1335 made Dukes of York and Gloucester respectively by their nephew Richard II. This king first extended the title beyond the royal house. In 1386 he made his favourite, Robert de Vere, Duke of Ireland, and in 1397 he created five dukes and a duchess in one day—viz. the Dukes of Hereford, Surrey, Exeter, Albemarle, and the Duke and Duchess of Norfolk. The creation of dukes was at that time by patent, there being an inaugural ceremony of girding with the sword in parliament. In the reign of Henry VI., the recipients of dukedoms included Humphrey Stafford, Duke of Buckingham, Henry de Beauchamp, Duke of Warwick, and William de la Pole, Duke of Suffolk. Henry VIII. made his illegitimate son, Henry Fitzroy, Duke of Richmond, and his brother-in-law, Charles Brandon, Duke of Suffolk. Three dukes were created by Edward VI., Edward Seymour (the Protector and king's uncle) being made Duke of Somerset; Henry Grey, Duke of Suffolk; and John Dudley, Duke of Northumberland. Yet on Elizabeth's accession, in consequence of attainders and extinctions, the only remaining duke was Thomas Howard, Duke of Norfolk; and on his execution and attainder, the title of duke was non-existent in England. James I. in 1623 made the Scottish Duke of Lennox Duke of Richmond, and his favourite, George Villiers, Duke of Buckingham. Charles I. conferred the dukedom of Cumberland on Prince Rupert. Charles II. (q.v.), besides creating General Monk Duke of Albemarle, and the Marquis of Worcester Duke of Beaufort, bestowed the dukedoms of Monmouth, Grafton, Northumberland, and St Albans on four of his natural sons. Under William, Anne, and George I. a number of holders of lower dignities in the peerage were advanced to the rank of duke. From the accession of George II. comparatively few dukedoms have been created, except those conferred on

younger members of the royal house. Since the accession of Henry IV., the dukedom of Lancaster has been merged in the crown; there was no Duke of York from 1827 to 1892; and the dukedom of Cornwall is held by the heir-apparent.

The introduction of the title duke into Scotland seems to have arisen out of the claims of precedence made by Henry IV., when Duke of Lancaster, over the Scottish princes, who were merely earls, at international congresses. The first Scottish dukes were made in 1398—viz. David, eldest son of Robert III., who was made Duke of Rothesay; and the king's brother, Robert, Earl of Fife and Menteith, who was made Duke of Albany (q.v.). The dukedom of Albany (the old name for Scotland) was an empty honour unconnected with lands, and the only instance of a Scottish dukedom that did not possess more or less of a territorial character. David, Duke of Rothesay, died without issue in Falkland Castle, in 1402, and in virtue, it has been assumed, of the original constitution of that dukedom, the title in later times belonged to the heir-apparent of the Scottish crown. Prince Henry, eldest son of James VI., was, at his baptism in the Chapel Royal at Stirling, invested with the dignity of Duke of Rothesay, with appropriate solemnities, including the imposition of a ducal crown. The title of Duke of Ross was given by James III. to his second son, James, who became Archbishop of St Andrews; and the same king, on the eve of the rebellion in which he lost his life, bestowed on his devoted adherent, David, Earl of Crawford, the title of Duke of Montrose. The dukedoms of Ross, conferred on Henry, Lord Darnley; of Orkney, bestowed on the Earl of Bothwell on his marriage with Queen Mary; and of Lennox, given to Esmé Stewart, Earl of Lennox, cousin-german of Darnley, were the only other Scottish creations before the union of the crowns. Hitherto the jealousy of the feudal nobles had been so great an obstacle to the extension of this title beyond the near relations of the royal house, that James, Earl of Arran, though regent of Scotland and next heir to the throne in Queen Mary's minority, had to derive his title of duke (Châtellerauld) from France. Ten Scottish dukedoms appear on the Union Roll of 1707, of which Hamilton alone dated before the Civil War. Rothesay, which had been overlooked, was added in 1714. Of these eleven dukedoms, two are extinct, and Queensberry is conjoined with Buccleuch. A duke (except a royal duke) in the peerage of the United Kingdom is styled 'Your Grace,' and 'The Most Noble.' His wife is a duchess. For the designation of his sons and daughters, see COURTESY TITLES. His parliamentary robe is of scarlet, with four doublings of ermine. For the form of his coronet, see CORONET.

Duke of York's School, an alternative name for the Royal Military Asylum (q.v.) near Dover.

Dukeries. See WORKSOP, and *The Dukeries*, by R. M. Gilchrist (1913).

Dukhobortzi ('Warriors of the Spirit'), a sect of Russian mystics, traceable to the middle of the 18th century, who depend upon an inward light, like the Quakers, attach little importance to the sacraments, priesthood, and services of the church, refuse military service, and reject the doctrine of the Trinity and the divinity of Christ. The Emperor Alexander I. allowed them to settle in Taurida, in South Russia; Nicholas I., in 1841, transferred them to Transcaucasia. In 1899 a body of them emigrated to Canada, where, in spite of occasional eccentricities, they have proved industrious and successful colonists in Saskatchewan and British Columbia. See RASKOLNIK; RUSSIA; Maude, *Peculiar People* (1905); *Chambers's Journal* for 1912.

Dukinfeld, a Cheshire municipal borough, adjoining Stalybridge; pop 20,000.

Dulce, a lagoon of Guatemala (q.v.) communicating with the Atlantic.

Dulce Domum, the famous song still sung, with the aid of a band, at Winchester College on the eve of the break-up day for the summer holidays. The origin of both words and music is very uncertain—it is usual to ascribe the former to one Turner, probably him who became Bishop of Ely and was one of the Seven Bishops under James II.; the latter, to Johannes Reading, organist of the college from 1681 to 1689. A school tradition makes both the work of a home-sick Wykehamist, who was kept at school during the holidays for a misdemeanour, and who played it incessantly until he pined away and died. See vol. ii. (pp 576-79) of Chappell's *Popular Music of the Olden Time*, where, with the Latin text and the music, a good translation by Bishop Charles Wordsworth is given.

Dulcigno (Serb *Učinj*, Albanian *Utkun*), a port of Yugoslavia, 20 miles SW. of Scutari. Old Dulcigno fell into the hands of the Turks in 1571. In the 16th and 17th centuries it was the most famous den of pirates on the Adriatic. In 1880, with the approval of Turkey, the representatives of the Western powers arranged that Dulcigno and its territories should become Montenegrin; and, after endless procrastination, the Turks expelled the Albanian troops by force, and the Montenegrins were able to take possession. Pop. about 5000.

Dulcimer, a musical instrument resembling a flat box, with sounding-board and bridges, across which run wires tuned by pegs at the sides, and played on by striking the wires with a small piece of wood in each hand, or more usually with two cork-headed hammers. The dulcimer in its simplest shape (closely akin to the psaltery, which, instead of standing on a table or on legs of its own, was carried in the hand like a harp) is one of the most ancient of instruments, appearing in Assyrian sculptures; and may be regarded as the ancestor of the piano. The cimbalom of Hungarian bands is essentially a dulcimer.

Dulong and Petit's Law. See ATOMIC THEORY.

Dulse (*Rhodymenia palmata*), a seaweed, one of the Floridæ (see SEAWEEDES), growing on rocks in the sea, and used as food by the poor on the coasts of Scotland, Ireland, and other northern countries. It is eaten raw or roasted, and with vinegar. It is an important plant to the Icelanders, and after being washed and dried, is stored in casks, to be eaten with fish or boiled with milk. In Kamchatka, a fermented liquor is made from it. Sheep are fond of it.—One or two other edible Floridæ bear the same name on different parts of the coast, and the pungent *Laurencia pinnatifida* is known as pepper dulse.

Duluth, a prosperous city of Minnesota, capital of St Louis county, and as a lake port one of the chief shipping centres in the United States, is picturesquely situated at the west end of Lake Superior, 156 miles NNE. of St Paul, and is the terminus of a number of important railways. It has one of the finest harbours in the United States, protected by a natural breakwater known as Minnesota Point, which is 7 miles long and about 750 feet broad. The navigable St Louis River affords also abundant water-power. The United States government has expended liberal sums of money in the improvement of the harbour, by dredging and the construction of piers. The ship-canal (depth about 23 feet) through Minnesota Point forms the chief entrance way between

Lake Superior and the harbour. The grain elevators handle vast quantities of wheat. Duluth imports coal and other commodities, and exports iron, copper, lumber, wheat, wool, hides, &c. The industries comprise extensive steel works, large flour and lumber mills, stockyards, slaughtering and cold-storage establishments, &c. Advantageously situated at the head of navigation of the great chain of lakes, and with immense deposits of iron, copper, granite, and freestone in the vicinity, the town has rapidly increased in population and in wealth. Pop. (1880) 3483; (1890) 33,115; (1900) 52,969; (1910) 78,466; (1920) 98,917. The city of Superior, Wisconsin, adjoins Duluth.

Dulwich, a beautiful suburb of London, in Camberwell, $\frac{1}{2}$ miles SSE. of St Paul's Cathedral, and a little to the west of Sydenham. It is noted for its college and picture-gallery.

DULWICH COLLEGE, or 'College of God's Gift at Dulwich,' was founded in 1619 by Edward Alleyn (q.v.) the actor. The old college buildings occupy three sides of a quadrangle, and comprise the chapel, chaplain's house, alms-rooms, and the Lower School, or Alleyn's School, in which 160 boys receive a second-grade education at a nominal fee. The Upper School, giving a first-grade education, was, in 1870, transferred to new buildings in the Italian style of the 13th century. It provides accommodation for about 600 boys. The foundation also includes an almshouse for the maintenance of twelve poor brethren, twelve poor sisters, and twelve out-pensioners. The picture-gallery, specially rich in Dutch paintings, had been collected for Stanislaus, king of Poland, and was bequeathed to the college by the painter, Sir P. F. Bourgeois (1756-1811).

Duma (in full, Gossudarstvennaya Duma, 'state council'), the elected house of the parliament of the Russian empire, first assembled 1906. The fourth Duma (1912-17) ended with the monarchy.

Dumas Davy de la Pailleterie, ALEXANDRE (1803-70), was the grandson of a certain Count (or Marquis) Alexandre Davy de la Pailleterie and Marie-Cessette Dumas, a pure-bred Haytian negress, and the son of General Alexandre Davy-Dumas—a brilliant and daring cavalry officer, 'the Horatius Cocles of the Tyrol'—and Marie-Louise-Elizabeth Labouret, daughter of a tavern-keeper and small landowner at Villers-Cotterets, and was technically, therefore, a quadroon. He was born and reared at Villers-Cotterets. The general, who had been put on half-pay by Napoleon, died when his son was four years old; and as the Emperor continued to behave as meanly to his widow and children as the First Consul to himself, the first years of a most prodigal life were years of decent penury and thrift. Dumas, who was afterwards an omnivorous reader, was an idle and unscholarly lad, and the local teachers could make nothing of him; but he had the run of the great forest about his native hamlet, he became an expert woodman, he developed a magnificent constitution, a turn for letters, and a very pretty talent at billiards, and when, at twenty or so, he got at last to Paris, he was physically as fit for the struggle for existence as any of the strong and ardent generation to which he belonged.

He began, through the influence of General Foy, as a clerk in the bureau of the Duc d'Orléans (afterwards Louis-Philippe); but his mind still ran on literature, and he spent some years in reading and in trying to learn to write. He had only published a volume of short stories, and collaborated—with Ph. Rousseau and young Adolphe de Leuven—in a couple of farces, when at seven-and-twenty he forced the door of the Théâtre Français with his first five-act play, *Henri Trois et sa Cour*

(1829), and at one stroke operated that revolution in the theory and practice of historical drama which the Hugolater is fond of ascribing to the poet of *Hernani* (1830). In 1831 he did the same for domestic tragedy—the *pièce* of MM. Augier and Sardou—with *Antony*, perhaps the boldest, adroitest, and completest achievement in plan, construction, and effect in the literature of the modern theatre; failed in verse with *Charles VII. chez ses Grand Vassaux*—an excellent play; and scored a tremendous success (in collaboration with Goubaux and Dinant) with *Richard Darlington*; and in 1832 he carried the romantic 'history' to what seems to be its culmination in *La Tour de Nesle* (in collaboration with Gaillardet). He was, indeed, the very genius of the stage. He broke ground with the ease, the assurance, the insight into essentials, and the technical accomplishment of a master, and he retained these qualities until the days of *Mme. de Chantelay* (1868) and *Les Blancs et les Bleus* (1869). His dialogue is bright, appropriate, vivid, eminently constructive and explanatory; he never eludes or tampers with his situation, but faces his problem boldly, and wrings his interest from the clash of character and the presentation of emotion in action; his plots are made and conducted with admirable adroitness and lucidity; his expositions are models of clarity; his effects are brought off with surprising certainty and vigour. 'All I needed,' he said of himself, 'was'—not scenery, nor choruses of monks, nor *Hernani's* horn, nor any merely decorative stuff of that sort—but 'four trestles, four boards, two actors, and a passion;' and the vaunt was absolutely justified. Dumas is the soundest influence in drama of the century, and to his example is owing not a little of the best of *Barrière* and *Augier* and the dramatist of *Monsieur Alphonse* and *Demise*.

The *romantiques* were a Byronic set, and Dumas, whose good temper was exuberant, and whose sense of the liveableness of life remained unalterable, was at first as Byronic as the rest. In 1832, however, he fell ill of cholera, went to Switzerland to recuperate, and wrote for the *Revue des Deux Mondes* the first of his famous and delightful *Impressions de Voyage*. He was fond of adventure and change; his capacity of producing agreeable and brilliant 'copy' was amazing; and these traveller's notes of his—in which a good deal of history and romance is worked in with abounding vivacity and wit—were among the best liked of his many benefactions to the public. He kept them going almost to the end. A prodigious worker (he would write for weeks on end, at the rate of sixteen or eighteen hours a day), he was wont, after months of production, to renew himself with a round of hundreds, or thousands, of miles; and he never failed to put the experience into print. Thus, *En Suisse* (1832) was followed by *Le Midi de la France* (1840), by *Les Bords du Rhin* and *Une Année à Florence* (1841), by *Le Spérone* and *Le Capitaine Arena* (1842), by *Le Corricolo* (1843)—it was of the last two it was said that Dumas had discovered the Mediterranean—by *De Paris à Cadix* and *Le Vélce* (1845), and, finally, after years of work on other lines, by *Le Caucase* (1859), *De Paris à Astrakhan* (1860), and *En Russie* (1865). All these are certainly his own. Of those that he redacted from the MSS. of other men it is unnecessary here to speak.

But it was as a story-teller pure and simple that Dumas was destined to gain the better and larger part of his abounding and enduring success. And this is perhaps the place to discuss the question of what is his own share in his own work. He exhausted, it appears, some ninety several collaborators, and his debates with certain among them—

with Gaillardet and Maquet, for example—by no means redounded to his credit. But it is none the less a fact that apart from him his assistants were mostly unreadable, while in conjunction with him they were Alexandre Dumas—that is to say, perhaps the most popular among modern novelists, and assuredly one of the greatest masters of the art of narrative in all literature. The truth, as stated by Edmond About, appears to be that Dumas took whatever he could get from whomever he could get it; that, the thing being carefully devised in consultation, the collaborator of the period was told off to prepare a first draft; and that Dumas re-wrote the result—'En y semant l'esprit à pleines mains,' says About—thus minting it in his own die, and informing it with his own immense and radiant personality. 'What a gainer you would be,' exclaims his son of him: 'rien qu'à reprendre ce que tu as donné!' and there is no doubt—for the present writer at least—that Dumas gave a vast deal more than he took. At the same time it is undeniable that his thefts were many and flagrant. Tielaun's *Adventures of a Younger Son*—to take but a single instance—appears in his collected works; and it is even told of him that he was with difficulty restrained from signing a book of the *Iliad*, which somebody else had run into prose to fill a gap in the columns of *Le Mousquetaire*.

He has told us that from the first it was a purpose of his life to put the history of France into novels; and his earliest essay was the *Isabelle de Bavière* of 1836. It was followed by *Pauline, Le Capitaine Paul*, and *Pascal Bruno* in 1838; by *Acté* in 1839; and by *Othon l'Archer, Le Capitaine Pamphile*, and *Maitre Adam le Calabrais* in 1840—all on other lines; and then the historical vein cropped up anew in *Le Chevalier d'Harmenthal* and *Ascanio*, both produced in 1843. For the amazing decade that was next to come there is no parallel in the story of literature except the first ten years of the author of *Waverley*. In 1844, with a number of digressions and excursions into new provinces—as *Océle*, *Fernande*, *Amavry*, *Sylvandire*, *Monte Cristo*—appeared *Les Trois Mousquetaires*; in 1845 *Vingt Ans après*, *La Fille du Régent*, and *La Reine Margot*; in 1846 *La Guerre des Femmes*, *Maison-Rouge*, *Le Bâtard de Mauléon*, *La Dame de Monsoreau*, and *Les Mémoires d'un Médecin*; in 1848—the *Théâtre-Historique* and a run through Spain, Algiers, and a part of Morocco having absorbed the greater part of 1847—*Les Quarante-Cinq* and the beginnings of *Bragelonne*, which was finished in 1850; and in 1849 *Le Collier de la Reine*. The next two years witnessed the production of work so varied as *La Tulipe Noire* and *Le Trou de l'Enfer* (1850), and *La Femme au Collier de Velours* (1851); but in 1852 the historical inspiration was again turned on, and the result was the masterpiece called *Olympe de Clèves*. Between that year and 1854 were produced the ten delightful volumes of *Mes Mémoires*, with *Ange Pétou* and *La Comtesse de Charny*, which were the work of 1853. Other achievements in the romance of French history were *Ingénue* (1854), *Les Compagnons de Jéhu* (1857), *Les Louves de Machecoul* (1859), and *Les Blancs et les Bleus* (1867-68), in which last the sequence at length found end. Other works of the same period, but done on other lines, were *Isaac Laquedem* (1858), which promised to be one of Dumas's best works; *Catherine Blum* (1854); *Les Mohicans de Paris* and *Salvator* (1854-59), in which is formulated the type of the French detective as he appeared to Gaboriau, Féval, and Ponson du Terrail; *Le Meneur de Loups* (1857); *Black* and *Le Capitaine Richard* (1858); *Le Père Gigogne* and *Le Père la Ruine* (1860); *Jane, Mme. de Chantelay* and *La Princesse Flora* (1861); *La San-Felice* (1862); and

La Terreur Prussienne (1867). In most of these there are touches of good Dumas; but the best period is that which begins with the *Mousquetaires* and ends with *Isaac Laquedem* and *Les Mohicans de Paris*.

The list is nothing like complete, nor have we space to do more than refer in passing and in general terms to the cloud of drama (all the great historical novels were cut out into great historical plays: the *Mousquetaires* cycle supplied at least three: as also were *Monte Cristo*, which was played in four parts, *Gabriel Lambert*, *Mme. de Chamblay*, and so forth), history, *causerie*, journalism, redaction, in whose midst this enormous production went on. In the same way and for the same reason we can only note that Dumas took active and conspicuous part in the Days of July; that in 1837 he received the red ribbon; that in 1842 he married Mlle. Ida Ferrier, from whom he promptly separated; that in 1855 he went into exile at Brussels, and stayed there two years; that from 1860 to 1864 he was in Italy, helping Garibaldi (whose life he wrote and who made him *Directeur des Fouilles at Pompeii*) and conducting and writing a journal; and that in 1868 he founded the *D'Artagnan*, published the *Histoire de mes Bêtes*, which of its kind is as good narrative as the first volume of *Monte Cristo* itself, and produced the last but one of his plays. By this time the end was near. *Procumbit humi* bos, says his son of the way in which he sank under his work. He had got rid of a series of fortunes (three-fourths of them were given away), and he quitted Paris for the last time with only a couple of napoleons in his pocket. He went to his son's villa at Dieppe, and there, on 5th December 1870, he simply faded out of being.

In life he was very much of a scapegrace and a madcap, and even more of a prodigal. His morals were loose, he was vain as only a man of colour can be, his literary conscience was (to say the least) imperfect, his veracity was that of Hugo and Berlioz and the *romantiques* in general; he could—and did—commit astonishing offences in taste; but his humanity was boundless in degree and incorruptible in quality, he was generous to a fault, he is not known to have dealt a single foul blow. 'I love and admire you,' said Michelet, 'for you are a force of nature.' 'Foncièrement bon,' was George Sand's verdict, 'mais . . . trop souvent ivre de puissance;' and the fact is that he was a prodigy of gaiety, kindness, and charm ('Il respirait la bonté,' M. Rodin told the present writer), and a prodigy of temperament and power and the capacity of life and invention and achievement. He talked still better than he wrote; and he wrote without any of those affectations of style which were the daily bread of many of the men of 1830, and with an ease, a gusto, a sincerity of mind, a completeness of method that are irresistible. And the lesson of his greater books—of the Valois cycle, for instance, and the long sequence of the *Mousquetaires*—is one by which the world may well have profited. Love, honour, friendship, loyalty, valour, the old chivalric virtues—these were his darling themes; and he treated them with a combination of energy and insight, of good sense and good feeling, of manliness of mind and beauty of heart, that has ranked him with the great benefactors of the race.

ALEXANDRE DUMAS, son of the preceding, was born (20th July 1824) in Paris when his father was but twenty-one years old. He was soon legitimised, and at sixteen, after a thorough course of training at the Institution Goubaux, and the Collège Bourbon, he left school for the world and letters and the society to which his father, then almost at his apogee, belonged. He was essentially respectable, however, and having sown a cer-

tain quantity of wild oats, and made a few experiments in literature, he settled down to serious work, and began to take life in earnest. He started in fiction; he went on to drama; he took to theorising about art, morals, politics, religion even, and succeeded in all. He was made a member of the Institute in 1874, and at his death, 27th November 1895, was acknowledged to be the best playwright, and one of the greatest artists in words of latter-day France.

His novels—from *La Dame aux Camélias* (1848) to *L'Affaire Clemenceau* (1897)—are all readable, and more often than not are worth reading. His essays, letters, speeches, prefaces, and prelections generally are brilliant and admirable in form, and in matter daring, paradoxical, suggestive in a very high degree. Of his sixteen plays, there is scarce one that is not literature, while five or six of them, as *Le Demi-Monde* (1855), *Le Fils Naturel* (1856), *Les Idées de Mme. Aubray* (1867), *Une Visite de Noces* (1871), *Monsieur Alphonse* (1873), *Denise* (1885), are masterpieces of construction, characterisation, and writing. Other famous dramas in which he had a share (and a very large one) are *Le Supplice d'une Femme* (1865), the chaotic original of which is due to Emile de Girardin; *Héloïse Parquet* (1866), in collaboration with M. Durantin; and *Les Danicheff* (1876). He may have assisted George Sand in preparing several of her novels for the stage—*Le Marquis de Villemer* among them—and he completed and produced his father's *Joseph Balsano* (1878).

He was a brilliant yet dubious combination of African and French. At bottom he was fantastic, mystical, violent, with a passion for abnormal problems and desperate solutions. But it is not for nothing that his mother was a Parisian: his method was logical to a fault, he built as for all time, he was an artificer even in theory, and his paradoxes are developed with scientific exactness and precision. A bitter and dazzling wit; an intelligence of uncommon energy, daring, and intensity; a morality that is so genuine as to be sometimes offensive; an incorruptible honesty; a style hard, polished, chaste, flexible as a perfect sword-blade; and a dramatic gift as real as his father's—these were his qualities, and they made him not only remarkable but distinguished. See Claretie, *Alexandre Dumas fils* (1883).

DUMAS, JEAN BAPTISTE ANDRÉ, a great French chemist, was born at Alais, Gard, 14th July 1800. He studied at Geneva, and coming to Paris in 1821, was first a lecturer in the École Polytechnique, then professor of Chemistry in the Athénée, the École Centrale des Arts et Manufactures (founded by himself), and finally, the Sorbonne. He now wholly devoted himself to chemical studies; and his views on chemical equivalents, and especially his memoir on the atomic theory, soon attracted attention over all Europe. His views on the laws of substitutions involved him in a long discussion with the great Berzelius. His researches in organic Chemistry (q.v.), especially his masterly papers on the ethers, ethereal oils, indigo, and the alkaloids, placed him in the first rank of chemists. In 1849-51 he was minister of agriculture and commerce, and he also held offices under the Second Empire. In 1875 he was called to fill Guizot's chair in the Academy; and he died at Cannes, 11th April 1884. His chief works are *Traité de Chimie appliquée aux Arts*, and *Leçons sur la Philosophie Chimique*. See a forty-page memoir by Prof. A. W. Hofmann in *Nature* for 1880; and Maindron, *L'Œuvre de J. B. Dumas* (1886).

Du Maurier, GEORGE LOUIS PALMELLA BUS-SON, caricaturist and book-illustrator, an English

subject, descended from a French family who fled to England at the time of the Revolution, was born in Paris, 6th March 1834. In 1851 he came to London, and studied chemistry at University College, but returning to Paris he adopted art as a profession, studying under Gleyre, and in Antwerp and Dusseldorf. In England he rapidly acquired reputation as a designer of exceptional dexterity. He illustrated Thackeray's *Esmond* and *Ballads*, Foxe's *Book of Martyrs*, &c.; and much of his work is to be found in *Once a Week* and the *Cornhill Magazine*. Joining the staff of *Punch*, he became the graceful satirist of modern fashionable life. He wrote originally for *Harper's Magazine* three novels illustrated by dainty drawings—*Peter Ibbetson* (1891), *Trilby* (1894, the phenomenally successful story of an artist's model in the Quartier Latin, dramatised in 1895), and *The Martian* (1897). In 1897 was published also *A Legend of Camelot. Pictures and Poems*. He suffered from failing sight, lectured for a while, and died 8th October 1896. See Moscheles, *In Bohemia with Du Maurier* (1896); T. M. Wood, *George du Maurier* (1913).—His son SIR GERALD (born 1873) became well known as an actor-manager.

Dumbarton, the county town of Dumbartonshire, lies mainly on the left bank of the Leven, a little above its influx to the Clyde, and 15 miles WNW. of Glasgow. Its High Street curves for five furlongs parallel to the Leven; and its chief public building is the Burgh Hall and Academy, a French-Gothic pile of 1866, restored since the fire of 1883. In 1658 the magistrates of Glasgow are said to have wished to make Dumbarton their harbour, but the offer was declined on the ground that 'the influx of mariners would tend to raise the price of butter and eggs to the inhabitants'; and in 1700 the right of levying dues on all vessels navigating the Clyde was sold to Glasgow for £260. Dumbarton now ranks merely as a sub-port; but its shipbuilding, with the subsidiary industries, has attained important dimensions since the opening of great shipyards in 1834 and 1844. Between the town and the Clyde rises the Rock of Dumbarton (280 feet), a double-peaked, basaltic eminence, which is crowned by the picturesque castle, a building of no great strength now or architectural merit, but one of the four Scottish fortresses that continued to be maintained after the Treaty of Union. Dumbarton was made a free royal burgh in 1222, and unites with Clydebank (since 1918) to return one member to parliament. Pop. (1851) 5445; (1881) 13,782; (1901) 19,985; (1921) 22,933. The capital of the Britons of Strathclyde, and termed by them *Alcluith* ('height on the Clyde'), by the Gaels *Dumbreathan* ('fort of the Britons'), Dumbarton has also been identified, more doubtfully, with the Roman *Theodosia*. Anyhow, the history of its Rock extends over more than a thousand years, from its capture by Picts and Northumbrians (756), by Vikings (870), to Wallace's captivity here (1305), the child Queen Mary's residence (1548), and its daring surprise by Craufurd of Jordanhill (1571). A younger son of the Marquis of Douglas was made Earl of Dumbarton in 1675, and he is referred to in the well-known song, 'Dumbarton's drums beat bonny, O!'

Dumbartonshire, a Scottish county, 25 miles long and $1\frac{1}{2}$ to $15\frac{1}{2}$ miles broad, with an area of 245 sq. m., of which 30 belong to a detached south-eastern portion. Loch Lomond (22 by 5 miles) lies on the eastern boundary, and sends off the Leven 7 miles to the Clyde; the southern is washed by the Clyde's broadening estuary; and the western, for 17 miles by its offshoot, Loch Long, which forms with the Gare Loch (7 miles by 7 furlongs) the wooded Roseneath peninsula. The surface, almost

everywhere hilly or mountainous, culminates in Ben Vorlich (3092 feet); and the scenery, with its sea-lochs, lake, woods, and glens, is lovely as that of few regions in Scotland. The rocks include mica-slate, sandstone, and limestone; and coal is mined in the detached portion, which nowhere exceeds 480 feet above sea-level. The climate is mild and humid. Barely a fourth of the entire area is in tillage; but many sheep and cattle are reared. Roseneath Castle is a seat of the Duke of Argyll. Since 1728 bleach and print fields, dyeing and cotton works, have multiplied in the Vale of Leven; shipbuilding is an important industry; and there is ample communication by steamboat and rail. The chief towns are Dumbarton, Clydebank, Kirkintilloch (in the detached portion), Helensburgh, Alexandria, and Renton. Dumbartonshire returns one member to parliament. Anciently part of the Levenach or Lennox, it retains some vestiges of Antonine's Wall, and has memories of St Patrick, Bruce, Rob Roy, Smollett, and Henry Bell. Pop. (1801) 20,710; (1881) 75,333; (1921) 150,861. See Joseph Irving's *History of Dumbartonshire* (1860; recast by John Irving, 3 vols., 1917-25), and *Book of Dumbartonshire* (1879), with Sir W. Fraser's *Chiefs of Colquhoun* (1860) and *The Lennox* (1874).

Dumb-bells, double-headed weights swung in the hands for the purpose of developing the arms, muscles of the chest, &c. See GYMNASTICS.

Dumb Cane (*Dieffenbachia seguina*), a plant of the order *Araceae*, aberrant in its almost abortive character, but agreeing with them in its acidity, which is in none of them more highly developed. It has a cylindrical stem, with ringed scars and oblongo-ovate leaves. It is a native of the West Indies, and has received its English name from the property which it has of producing dumbness when chewed, its acrid poisonous juice causing an immediate swelling of the tongue, accompanied with excruciating pain. It has, however, been used medicinally. Many species and varieties of *Dieffenbachia* are in cultivation as foliage plants.

Dumbness. There is hardly any condition of the vocal organs compatible with life in which speech is entirely prevented; for when the larynx is so diseased that no voice-sounds are produced there (Aphonia, q.v.), whispering is in general still possible. Even after complete removal of the tongue, tolerably good power of articulation may be recovered. Only when the larynx is completely obstructed, so that no air can pass by the mouth, and breathing is carried on entirely through a tracheotomy tube, is speech rendered impossible.

The usual causes of dumbness are, first and most important, deafness, congenital or occurring in early life; and even this, patient training (see DEAF AND DUMB) is able to overcome, showing clearly that it is the want of hearing the sounds to be imitated which leads to the absence of speech in so-called 'deaf-mutes'; secondly, morbid conditions of the brain and nervous system, idiocy, hysteria and allied conditions, localised disease of the brain (see APHASIA). Lunatics and malingerers sometimes maintain silence for long periods. It occasionally happens that a child, obviously not deaf nor unintelligent, from diffidence or laziness, does not begin to speak till long past the usual age, but persists in expressing his meaning by signs. This can usually be remedied by sending him to live for a time among strangers, by whom his signs are not understood.

Dum-dum. See KALA-AZAR.

Dumdum (*Dam Damá*), a municipality $4\frac{1}{2}$ miles NE. of Calcutta. Pop. with troops, 13,000. This was the scene of the first open manifestation against

the greased cartridges, in the sepooy mutiny of 1857. There is an arsenal and a manufactory of ammunition. The name is associated with 'expansive' bullets first made there; but the Dumdum bullets are not all necessarily of that nature.

Dumfries, the county town of Dumfriesshire, the 'Queen of the South,' stands on the Nith's left bank, and is connected with its Kirkcudbrightshire suburb of Maxwelltown by three bridges, of which the middle one was founded about 1280 by Deivorgilla Baliol. By rail it is 90 miles S. by W. of Edinburgh, and 33 WNW. of Carlisle. Corbelly Hill, in Maxwelltown, on which are a Catholic convent (1882) and an observatory, commands a splendid view of the surrounding hills, the Solway Firth, and the Cumberland Mountains. Dumfries itself is scattered somewhat irregularly over a gentle elevation. It is built of red sandstone, and among its chief edifices are the Scottish baronial county buildings (1866); the post-office (1887-88); the Mid Steeple (1707), ascribed to Inigo Jones, but really by one Tobias Bachup of Alloa; Greyfriars' Church (rebuilt 1867), with a spire of 164 feet; the Academy (1802); and, in St Michael's churchyard, the mausoleum (1815) of Robert Burns, who here spent his last five years in a small house still standing, and a statue of whom was erected in 1882. The Crichton Institution (1835-70) is a lunatic asylum; rather nearer is the infirmary (1871). The manufacture of tweeds, introduced in 1847, is the leading industry. Hosiery ranks next: and there is a busy trade, both local and transit, pork and live-stock being staple commodities. The opening, however, of the railways in 1850-69 has greatly diminished the river traffic, though large sums had previously been spent in improving the 14 miles of the Nith's channel between the town and the Solway. Dumfries was made a royal burgh by David I., and it united till 1918 with Annan, Kirkcudbright, Lochmaben, and Sanquhar in returning one member to parliament. Pop. (1851) 13,166; (1921) 15,778. For the town's memories of Bruce and Burns, of Border wars, and of both the '15 and the '45, see W. M'Dowall's *History of Dumfries* (2d ed. 1873).

Dumfriesshire, a Scottish Border county, bounded SE. by Cumberland, and S. for 21 miles by the Solway Firth. Its greatest length, from south-east to north-west, is 53 miles; its breadth varies between 13 and 32 miles; and its area is 1103 sq. m. From Clydesdale and Tweeddale it is shut off by a sinuous rim of high green rounded mountains—Lowther Hill (2377 feet), Queensberry (2285), Hartfell (2651), White Coomb (2695), and Ettrick Pen (2269). Thence, though broken by Cairnkinna (1819 feet), Birrenswark (920), and some lesser eminences, the surface has a general southward slope to the dead level of Lochar Moss, a peat bog, 10 by 3 miles, now largely reclaimed. Three beautiful rivers, the Nith, Annan, and Esk, all run to the Solway; and the Annan belongs wholly to Dumfriesshire. At Moffat are mineral springs. Besides several lakes round Lochmaben, there is 'dark Loch Skene' ($\frac{1}{2}$ by $\frac{1}{4}$ mile; 1680 feet above sea-level), which has its outlet by a waterfall, the Grey Mare's Tail. The Enterkin Pass has been rendered famous by Defoe and Dr John Brown. The strata are Silurian, Old Red Sandstone, Carboniferous, and Permian, with intrusive igneous rock; reptilian footprints have been found in the sandstones of Corncockle Moor, in Annandale. The minerals include coal (at Sanquhar and Canonbie), sandstone, limestone, antimony (no longer worked), and (at Wanlockhead) lead, silver, gold. The climate is mild, with a mean temperature of 45° F. Only about a fifth of the entire area is arable, the uplands being pastoral

or waste. Sheep, cattle, and pigs are largely reared; and there are valuable salmon-fisheries. The county is traversed by two chief lines of railway (1849-50). It returns one member to parliament. Towns and villages are Dumfries, Annan, Lochmaben, Sanquhar, Moffat, Lockerbie, Langholm, Ecclefechan, Thornhill, and Gretna Green. Drumlanrig Castle (1689), a seat of the Duke of Buccleuch, is the chief mansion. Among antiquities are Roman stations at Birrens (excavated in 1895) and Birrenswark, Ruthwell (q.v.) Cross, and the castles of Lochmaben and Caerlaverock. Among its families are the Maxwells, Johnstones, Jardines, Kirkpatrickes, and Douglasses; among its worthies, Bruce (probably not a native), Allan Cunningham, Thomas Carlyle, and (by residence) Robert Burns. Pop. (1801) 54,597; (1881) 76,140; (1921) 75,365. See Sir H. Maxwell's *History of Dumfriesshire* (1896).

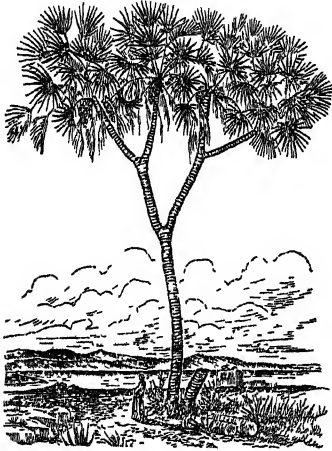

Dumont, PIERRE ÉTIENNE LOUIS, the apostle of Benthamism, was born at Geneva, 18th July 1759, and in 1783 accepted the charge of the French Protestant Church at St Petersburg. In 1785 he became tutor in London to the sons of Lord Shelburne, afterwards Marquis of Lansdowne. His superior talents, liberal sentiments, and fine character soon recommended him to the illustrious Whigs of that period; with Komilly, in particular, he formed a close friendship. During the early years of the French Revolution, Dumont was at Paris, where he became greatly attached to Mirabeau, regarding whom he has given the world much valuable information in his posthumous *Souvenirs sur Mirabeau* (1832). In this work he claims to have composed for him many of Mirabeau's most eloquent speeches. In 1791 Dumont returned to England, and formed an intimacy with Bentham (q.v.), whose unpublished works he abridged and edited. He returned to Geneva in 1814, and became a member of the representative council. He died at Milan, 30th September 1829.

Dumont d'Urville, JULES SÉBASTIEN CÉSAR, born at Condé in Calvados, 23d May 1790, entered the navy in 1807. Sent as captain of the corvette *Astrolabe* to obtain tidings of La Pérouse, he made a three years' voyage (1826-29) in southern seas, and made surveys of parts of the coast of Australia, Tasmania, New Zealand, the Fijis, New Caledonia, &c. His *Voyage de Découvertes* (22 vols.) contains records of this voyage, and of his botanical and entomological observations. In 1837-40 he made a great voyage of antarctic exploration, discovering Joinville Island and Adélie Land. The record of this *Voyage au Pôle Sud* (1854) comprises 22 vols. He died a rear-admiral, 8th May 1842.

Dumouriez, CHARLES FRANÇOIS (1739-1823), a French general, was born at Cambrai, son of an army commissary who was also a fair poet. At eighteen he entered the army, and served with distinction during the Seven Years' War until the conclusion of hostilities in 1763. After some time spent in rambling travel, he was appointed by Choiseul army quartermaster-general, and was next employed on a secret mission to Poland. On his patron's fall, he was recalled. He was flung into the Bastille, and afterwards imprisoned at Caen, whence he was set free by Louis XVI. and appointed commandant of Cherbourg. As the Revolution drew on, Dumouriez began to attach himself more closely to the popular party, and in 1790 became connected with the Jacobin Club, and during the same year was appointed commandant at Nantes. He now attached himself to the Girondists, and through their influence held for a short time the office of Minister of Foreign Affairs, which he resigned to take the field. The allies were advancing in great force. By a series of bold and

rapid manœuvres, Dumouriez prevented the enemy from sweeping over the plains of Champagne, and finally took up his position at Grand-Pré. Success quickly arrived, and the victory at Valmy (q.v.) compelled the invaders to retreat. It was mainly the admirable strategy of Dumouriez at this critical period that saved France. In 1792 he overthrew the Austrians at Jemappes; but in 1793, at Neerwinden, he sustained a severe defeat. Denounced as a traitor, he fled to the Austrian camp. After wandering through Europe, he settled in England. Besides his *Mémoires* (1794), see the German Life by Boguslawski (1878-79).

Dum Palm (*Hyphæne crinita*, *H. thebaïca*), a genus of palms, allied to the fan-palm (*Chamaerops*), but remarkable for the repeated fork-like branching

Dum Palm (*Hyphæne crinita*).

of the stem. It is abundant in Upper Egypt and Central Africa, sometimes growing amidst the very sands of the desert. The spongy tissue of the pericarp is eatable, and resembles gingerbread in flavour.

Dun, a root borrowed from Celtic by the Teutonic languages, signifying a hill or height. Besides giving rise to the Fr. *dunes*, Ger. *dunen*, Eng. *downs*, it enters extensively into the names of places (becoming often *dum*, *don*), as *Dunkirk*, *Dumbarton*, *Donegal*. The adverb *down* comes through *adown* from *of dūne*, 'off the hill.' And see HILL-FORTS.

Dūna. See DWINA.

Dūnaburg (Lettish *Daugavpils*, Russian *Dvinsk*), a town of south-eastern Lettland, with some manufactures and a large trade, on the Dūna, in the district of Latgale, 120 miles SE. of Riga, is of great military importance, owing to the strength of its fortifications. It was formerly the capital of Polish Livonia. Taken in 1920 from the Bolsheviks by the Poles, it was handed over to the Letts. Pop. 40,000.

Dunajec, a river of Poland, formed by two streams that rise in the Tatra, flows generally north-eastwards by Neu Sandec (Nowy Sącz) to the Vistula, about 40 miles below Cracow. It marks the line of the Russian front in 1915 in the Great War.

Dunbar, a town on the rocky coast of Haddingtonshire, backed by the Lammermuirs, 29 miles E. of Edinburgh by rail. Little remains of its sea-built castle, the stronghold from 1072 to 1435 of Gossipatric and his descendants, the Earls of Dunbar and March. It stood many sieges, the most famous that of 1339, when 'Black Agnes' held it for six weeks against the English; but it was dismantled in 1568, the year after Queen Mary's abduction thither by Bothwell. Dunbar was the scene, too, of Cromwell's great victory over Leslie, 3d September

1650. Chief buildings are the barracks and the parish church, which, rebuilt in 1821, has a tower 108 feet high. Fishing is the principal industry. The Victoria Harbour was formed in 1844. Dunbar was created a royal burgh by David II., and till 1885 it united with North Berwick, Jedburgh, Haddington, and Lauder in sending one member to parliament. Pop. 3800.

Dunbar, PAUL LAURENCE (1872-1906), poet, born at Dayton, Ohio. His parents had been slaves, and he himself became a lift-boy. For a short time he tried journalism, and was employed in the Library of Congress. To his *Lyrics of Lowly Life* (1896) W. D. Howells wrote an introduction, drawing attention to him as 'the only man of pure African blood and of American civilisation to feel the negro life æsthetically, and express it lyrically.' Later volumes are *Lyrics of the Hearthside* (1899), *Lyrics of Love and Laughter* (1903), and *Lyrics of Sunshine and Shadow* (1905), in which the best work is in negro dialect. He also wrote some novels.

Dunbar, WILLIAM, by general consent the greatest of Scottish poets before Burns, was apparently a Lothian, probably an East Lothian, man, but his family and the time and place of his birth are unknown. From Walter Kennedy's clumsy attack upon Cospatrick in the *Flying*, it has been inferred that Dunbar was of the family of the Earls of March. That he was or claimed to be of noble birth appears from his poetical begging-letters to King James IV. From childhood he had been taught to look forward to a bishopric, the preferment which a landless cadet considered his due; but 'the lerit sone of erll or lord' was set at table below a prelate 'that vont was for to muk the stabell.' In 1477 Dunbar appears in the records of St Andrew's University as Bachelor of Arts, and in 1479 as Master. He may have studied also in Paris. In his *Vindication of St Francis*, a fiend in the form of the saint urges the Franciscan habit upon him, as the brethren had often done before, but Dunbar leaps aside from it, excusing himself on the ground that among the saints he knows of seven bishops to one friar:

Quhairfoir ga bring to me ane bischopis weid,
Gife evir thow wald my saule yeld into Hevin.

The wording of the poem does not make it clear whether Dunbar had ever taken the vows of the order; if so, he had in some way been freed from them, and the friars had impudently told him to return. At all events, many years ago he 'did beir the freiris style,' and he had travelled through England and Picardy in friar's habit, preaching and flattering. His confession of 'mony wrink and wyle' practised by him at that time, has set his biographers imagining anything from Bohemianism to highway robbery and murder. However likely *a priori*, such conjectures are unsupported by evidence. Probably about 1490 he attached himself to the service of James IV. It is clear that he travelled much on the Continent on the king's business, but as the public records do not, as a rule, afford means of determining which embassies he accompanied, one is driven to seek information in *The Flying of Dunbar and Kennedy*. The two poets in this playful contest in scurrilous vituperation are under no restrictions as to the truth of their libels, and the doubtful order of the stanzas makes it difficult to make out the story at all. It is certain, however, that parts were written by Kennedy when Dunbar was believed to be in Denmark and in Paris. Dunbar tells how his ship was driven along the coasts of Holland, Denmark, and Norway, till those on board were famished. Kennedy refers to difficulty in crossing the Alps, and to a voyage from the Forth in the *Katherine*. The *Katherine* was the ship that carried Bothwell and

Blackadder to France in 1491. Dunbar seems to have been attached to this embassy. He may have accompanied Blackadder to Spain and Rome in 1494-96. *Of the Worldis Instabilitie* apparently reminds the king of services at home and in France, England, Ireland, Germany, Spain, and Italy. In 1500 he was granted a pension of £10 a year for life, or until he should be promoted by the king to a benefice of £40 or more. The instalment due in December of the next year was 'payit to him effir he com furth of Ingland.' This renders it all but certain that he was 'the Rhymor of Scotland,' official or unofficial, who received gifts from Henry VII. at that time, and that he was the author of the poem in praise of London which an English chronicler transcribes, under the year 1501, with this introduction, which might be biographically useful were it not ambiguous: 'This yere in the Cristmas weke the Mair had to dyner the Ambassadors of Scotland, whom accompanied my lord Chaunceler and other lordes of this Realme; where sitting at dyner one of the said Scottes givng attendaunce vpon a Bisshop, ambassadour, the which was reported to be a prothonotary of Scotland and seruauant of the said Bisshopp, made this Balade folowyng.' The ambassadors, who included Andrew Forman, Apostolical Protonotary and Bishop Postulate of Moray, had gone to London to conclude the marriage of James and the Princess Margaret. With Anglophil leanings, Dunbar henceforward attaches himself to the queen. His best work, outside of satire and realism, is undoubtedly *The Thrissill and the Rois*, a heraldic allegory of the approaching royal marriage, in which the aureate vocabulary, in other hands heavy, perfunctory, and conventional, is at its worst melodious, and at its best passes into another style by which brilliant pre-Raphaelite effects are achieved. In this poem, and in the similar dream-allegory, *The Goldin Terge*, the old motifs of the rose garden and the May morning have new life given to them by the poet's genius; but they can hardly be said to be rejuvenated. *Sen that I am a presoneir*, however, comes nearer to Henryson's freshness.

Dunbar's pension was raised in 1507 to £20, and in 1510 to £30, and the king was accustomed to allow him a new gown at Yule. In return he seems to have combined the functions of court chaplain and court poet. In March 1503-4 the king's offering 'at Maister William Dunbarris first ines' was seven French crowns. Many of the poems are connected with the amusements of the court, as those on the negress in whose honour a tournament was proclaimed; on a dance in the queen's chamber; on the Abbot of Tunland, who made himself wings, and came to grief in an attempt to fly. Dunbar is seldom content with such a mere record of the facts as the narrative of the queen's visit to Aberdeen in 1511. He boldly transfers *The Dance of the Sevin Deidly Synnis* and *The Tournament* between a tailor and a souter, from the court of Scotland to the court of Hell. Extravagant, boisterous humour, scalding satire, and Rabelaisian realism run through his most characteristic work. The grotesque vividness of *The Sevin Deidly Synnis* is perhaps unequalled in the language. The same command of metre and vocabulary which made possible the verbal melody of *The Merle and the Nyctingail*, and *Done is a battell on the dragon blak*, is used in *The Dance* to render the hurly-burly of Hell on a day of pageantry; in *The Fenyet Freir of Tunland* to give the clamour of birds; and in *The Flyting* words clatter like sword-blades. Appeals to the king to grant a benefice are numerous and varied. Dunbar seems to have grounded his hopes mainly on the queen's influence. The disappearance of his name from the Treasurer's Accounts after Flodden may therefore mean that

Margaret had preferred him to a benefice. His religious poems have been assigned, for no very convincing reason, to the period of retirement from court supposed to follow. The only evidence that he survived Flodden is the colophon of *Ane Orison*: 'Quod Dunbar quhen the Gouernour past in France;' which would indicate that he was alive in 1517. Lyndsay's *Testament and Complaynt of the Papyngo*, written in 1530, speaks of him as dead.

From that time, though his influence can be traced at least as late as George Buchanan and Alexander Montgomerie, his name is scarcely to be found for two centuries. Allan Ramsay then discovered his poems in the Bannatyne MS., and printed some in mangled form in *The Evergreen* (1724). Hailes and Pinkerton continued what Ramsay began. Dunbar was known, though but slightly, to Burns, to whose genius his own, except on the purely lyrical side, is close akin. Dunbar was a Chaucerian with limitations; and he was much more than a Chaucerian. To the mature Chaucer he owes little. Unless *The Freiris of Berwik* be his, he shows no trace of the *Canterbury Tales*, except, perhaps, in *The Tua Marit Wemen and the Wedo*, where the theme of the *Wife of Bath's Prologue* is placed in gorgeous setting, and worked out with daring and unexpected success in the old alliterative verse that Chaucer despised. He is greatest as humorist, satirist, and master of technique, and in all respects shows that he belongs to a grimmer and more fiercely personal age than Chaucer. He passes out of the rose garden into the world of Villon.

Some of Dunbar's poems were printed by Chepman and Myllar (1508; ed. Stevenson for the Scottish Text Society, 1918); the rest are for the most part preserved in the great manuscript collections, for which see the Scottish Text Society's editions. David Laing's edition of Dunbar's works (1834-65) has been superseded by that of the Scottish Text Society (ed. A. J. G. Mackay and others, 1893), and by Professor Schipper's (Vienna, 1894). Dr Baidon's (1907) is inferior but easier of access and manipulation. See Lives by Dr Schipper (1884) and Oliphant Smeaton (popular, 1898); the various histories of English and Scottish literature; Professor G. Gregory Smith in the 'Cambridge English Literature' (vol. ii. 1908), and his *Transition Period* (1900).

Dunbarton. See DUMBARTON.

Dunblane, an old-fashioned town of Perthshire, delightfully situated on the left bank of Allan Water, 5 miles N. of Stirling by rail. Founded by St Blane, a 7th-century bishop, its church was rebuilt in 1141 by David I. as a cathedral; but except for the Romanesque four lower stages of the steeple (123 feet), that cathedral is now a First Pointed edifice of a hundred years later—its glory the west window, of which Ruskin said he knew 'nothing so perfect in its simplicity.' The choir, with its carved oak stalls, was restored in 1873; the ruinous nave in 1891-95. In 1661 the saintly Robert Leighton chose Dunblane as the poorest and smallest of Scotland's sees; his path near the river still bears the name of the Bishop's Walk, and the library which he bequeathed to his diocese is still preserved in the town. There are also a mineral spring, the Queen Victoria school for soldiers' children, and a fine hydropathic (1876); 2½ miles to the east is the battlefield of Sheriffmuir. Pop. 3000.

Duncan, ADAM, VISCOUNT (1731-1804), admiral, was born at Dundee, and, entering the navy in 1746, commanded the *Valiant* at the reduction of Havana (1762). Save at the battle of Cape St Vincent (1780), he had little opportunity of distinguishing himself during thirty-three years, though he had risen to be admiral, when in 1795 he was appointed to the command of the North Sea squadron, with the special design of watching the Dutch fleet. Duncan's blockade of the Texel was

one of the most effective on record, and the Dutch trade was almost ruined. In the spring of 1797 the mutiny of the *Noie* spread to Duncan's seamen, and his position was for some weeks very critical. But the insubordination was ultimately quelled; and on the 11th of October he gained the brilliant victory of Camperdown (q.v.). He was rewarded with the title of Viscount Duncan of Camperdown. See *Life* by third earl (1898).

Duncan, HENRY, D.D. (1774-1846), from 1798 was minister of Ruthwell, in Dumfriesshire, where, in 1810, he established the first savings-bank. See *Life* by his great-granddaughter, Mrs Hall (1910)

Duncan, THOMAS, R.S.A. and A.R.A. (1807-45), was born at Kinclaven, Perthshire. He studied in the Trustees' Academy, Edinburgh, under Sir William Allan; and was his successor as headmaster of that school, and one of the most distinguished members of the Royal Scottish Academy. His portraits, and historical and fancy subjects, evince delicate feeling for female beauty, and keen appreciation of the humorous in Scottish character. His drawing is always careful and correct, and his colouring is especially remarkable for delicacy and richness.

Duncansbay Head (also DUNCANSBY), a promontory, 210 feet high, forming the north-east extremity of Caithness, $1\frac{1}{2}$ mile E. of John o' Groat's House, and 18 N. by E. of Wick.

Duncker, MAXIMILIAN WOLFGANG (1811-86), was born at Berlin, son of the bookseller, Karl Duncker (1781-1869). After studies at Bonn and Berlin, and six months' political imprisonment, he studied history at Halle, became extraordinary professor there in 1842, supported the right centre in the National Assembly in 1848, and the Old Liberal party in the Prussian chamber in 1849-52. He obeyed a call to a Tübingen chair in 1857, whence he was recalled to Berlin to fill a position in the ministry of state. In 1867-74 he was director of the state archives of Prussia. His greatest work is his *History of Antiquity* (5th ed. 9 vols. 1878-86; trans. by Evelyn Abbott, 1877-82). See the *Life* by Haym (1891).

Dundalk, a thriving Irish seaport-town, the capital of County Louth, situated on Dundalk Bay, 55 miles north of Dublin, and 58 south of Belfast by rail. It has salt-works, a distillery, iron-foundries, flax-spinning, brewing, and shipbuilding. There is a brisk export trade, especially in the grain, dairy products, and live-stock of counties Louth, Monaghan, and Cavan, with Liverpool and Holyhead (79 miles across), and through its branch railway to Greenore, also with other ports. The harbour has been much improved. Pop. (1871) 11,327, nine-tenths Roman Catholics; (1911) 13,128. It sent one member to parliament till 1885. Edward Bruce took Dundalk in 1315, and held his court here till killed in battle three years later. It was taken by Cromwell (1649) and by Schomberg (1689).

Dundas, (1) a baronial castle, dating from the 11th to 15th centuries, with modern additions, on the south bank of the Firth of Forth, near South Queensferry, the seat from about 1124 till 1875 of the family of Dundas.—(2) A town of Wentworth county, Ontario, at the head of Burlington Bay, at the west of Lake Ontario, with a number of mills and manufactories. Pop. 5000.—(3) An island of British Columbia, 40 miles NE. of Queen Charlotte Island, and separated by Chatham Sound from the most southerly of the Alaskan islands.—(4) A group of nearly 500 islets (also called the Juba Islands), all of coralline formation, lying off the east coast of Africa, in about 1° S. lat., with only one secure harbour.—(5) A strait in North Australia, separating Melville Island from Coburg Peninsula, about 18 miles broad.

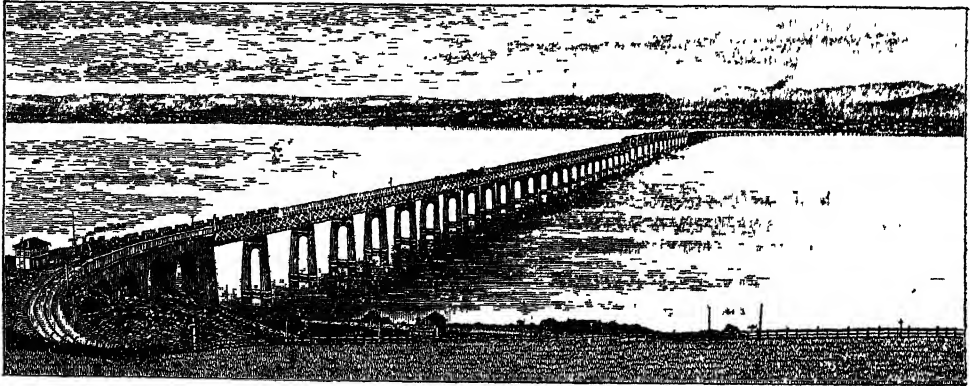

Dundas (of Arniston), the name of a Scottish family singularly distinguished for legal and political talent. Sir James Dundas, the first of Arniston, received the honour of knighthood from James VI., and was governor of Berwick. His son, Sir James Dundas, was appointed a judge of the Court of Session in 1662, and took his seat on the bench under the title of Lord Arniston, but was soon after deprived of his office for refusing to abjure the 'National and Solemn League and Covenant.' He died in 1679. His eldest son, Sir Robert Dundas, who also rose to the bench, died in 1726.—**ROBERT DUNDAS**, the son of the preceding, was born 9th December 1685; became a member of the Faculty of Advocates in 1709; and in 1717 was appointed Solicitor-general for Scotland, an office which he filled with great ability in a period of much political confusion. In 1720 he was made Lord Advocate; and in 1722 was chosen to represent Midlothian in the British parliament, where he honourably distinguished himself by his attention to Scottish affairs. Sir Robert Walpole coming into power in 1725, Dundas resigned his office, when he was elected Dean of the Faculty of Advocates. In 1737 he was raised to the bench, when, like his father and grandfather, he took the title of Lord Arniston. On the death of Lord President Forbes of Culloden in 1748, he was appointed his successor. He died in 1753. As an advocate, Dundas was a powerful and ingenious reasoner, and though somewhat disliked on the bench, his ability was universally admitted.—**ROBERT**, his eldest son, was born 18th July 1713, studied at Edinburgh and Utrecht, was admitted to the Scottish bar in 1738, and rose to be Lord Advocate (1754) and President of the Court of Session (1760). He died at Edinburgh, 13th December 1787. See *The Arniston Memoirs*, by George W. T. Omond (1887).

Dundas, the **RIGHT HON. HENRY, VISCOUNT MELVILLE** and **BARON DUNIRA**, brother of the preceding, was born 28th April 1742, and educated at the High School and university of Edinburgh. He was admitted a member of the Scottish bar in 1763. As a younger son of a petty numerous family, his circumstances were rather straitened; but his assiduity, his large share of the family talent and presumably also of the family influence, soon procured him advancement in his profession. He was successively appointed Deputé-advocate and Solicitor-general. In 1774 he was returned to parliament for Midlothian, in 1775 was appointed Lord Advocate. Two years later, he was made keeper of the King's Signet for Scotland. Dundas's career in parliament was highly successful, though not very creditable to his political consistency. Although elected in opposition to ministerial influence, he soon allied himself with the party in power, and became a strenuous supporter of Lord North's administration, being one of the most obstinate defenders of the war with the American colonists. When Lord North resigned in 1781, Dundas continued to hold the office of Lord Advocate under the Rockingham ministry. On the question of the war with America, Dundas had been opposed to Pitt; but when the Coalition Ministry was formed by Fox and Lord North, he passed over to the side of his old opponent, and became Pitt's ablest coadjutor. When Pitt returned to power in 1784, Dundas was appointed President of the Board of Control. That same year he introduced a bill for restoring the estates in Scotland forfeited on account of the rebellion of 1745. In 1791 he was appointed principal Secretary of State for the Home Department. He also held a great number of other offices, one of which, the treasurer-ship of the navy, involved him some years after in much trouble. Dundas's aptitude for business was undeniable. Many of the most important public

measures originated with or were directly promoted by him. Among such were the formation of the fencible regiments, the supplementary militia, the volunteer corps, and the provisional cavalry; in short, the whole of that domestic military force raised during the war consequent on the French Revolution. When Pitt resigned in 1801, Dundas did the same. In 1802, under the administration of Mr Addington, he was made Viscount Melville and Baron Dunira. In 1805 he was accused of 'gross malversation and breach of duty' while acting as treasurer of the navy. The trial commenced 29th April 1806; but in spite of the splendid array of Whig talent against him, Dundas was acquitted on all charges involving his honour, 'though it must now be allowed,' says Lockhart, 'that the investigation brought out many circumstances by no means creditable to his discretion.' Thereafter he lived mostly at Dunira, his seat near Comrie. He died at Edinburgh, 28th May 1811. A stately column, surmounted by a statue, was erected to his memory in Edinburgh in 1821, by officers and seamen of the navy. See Life by J. A. Lovat Fraser (1916), and Omond's *Lord Advocates of Scotland* (1893).

Dundee is perhaps *Dun-Tay*, the 'hill or foit on the Tay.' The Latin form was *Taodunum*. Boece

gives the fanciful version *Deidonum*, the 'gift of God.' *Dunde* appears to be the oldest form of the name, and occurs in documents of the 11th century. Dundee is a city in Forfarshire, on the N. bank of the Tay estuary, here 2 miles broad, and 10 miles from the river-mouth; 59 miles NNE. of Edinburgh, 20 ENE. of Perth, and 14 S. by W. of Forfar. In population it is the third town in Scotland. The city proper stands mainly on the slopes between the Law (571 feet high, composed of trap, and showing traces of ancient vibration), Balgay Hill, and the Tay. The most striking architectural features of the town are the town-house, erected by the 'Elder Adam' in 1734, in the Roman Ionic style, with a spire 140 feet high; the Albert Institute (erected 1867, from designs by Sir Gilbert Scott), and Victoria Galleries (1889), containing free library, museum, and picture galleries; the Royal Exchange, in the Flemish Pointed style of the 15th century, opened 1856; the Eastern Club-House; the Kinraid Hall, holding 2000 people; the Royal Infirmary, opened 1855, and largely extended in 1899 and 1907; the post-office; the technical college and school of art; the high school; the Morgan Academy; Dens Road School; the Provincial Training College; St Paul's Episcopal Church; Balgay Industrial School; the branch public lib-

Tay Bridge, looking towards Dundee.

raries; the Tower of St Mary, called the 'Old Steeple,' 165 feet high, and dating from about the 15th century (restored 1872).

The most important addition to the architecture of Dundee in recent years is the building containing the Caird Hall and the new Council Chambers. This structure took its origin in April 1914, when Sir James Caird, Bart., offered £100,000 for the purpose. He did not live to see the building completed; but his sister and heiress (Mrs Marryat) gave an additional sum of £75,000. The hall was opened in 1923. It is seated to accommodate 3300 persons. All the municipal departments are provided for within the same building, which also includes the Marryat Hall for special functions.

Dundee College was founded in 1880, when Miss Baxter of Balgavies gave a donation of £120,000, and Dr Boyd Baxter the sum of £10,000, and teaching was commenced in 1883. In 1890 it was affiliated to the university of St Andrews, the college retaining its individuality and a measure of financial authority, under the terms of the agreement. In 1895 the union was dissolved, but was reconstituted in 1897.

Dundee's public parks include the Baxter Park, 36½ acres; Balgay Park, 35½ acres; Loches Park, 23 acres. In 1912 Sir James Caird presented the Den of Mains as a pleasure-ground for the citizens.

Dundee is the chief seat in Great Britain of the

manufacture of coarse linen fabrics (Osnaburghs, sheetings, ducks, dowlas, drills, canvas, and cordage). But since 1855 jute has formed the staple trade of the city. The raw material is imported from India, and the products are yarns, bags and sacks for grain, coffee, guano, and other commodities, tarpaulins, coveis, and Hessian cloth (the foundation of linoleum), and carpets of great beauty. The trade in preserves and confectionery is important. The 'whalers of Dundee' have been world-famous owing to their employment in Antarctic exploration; but in recent years the whaling industry has been much restricted. Ship-building and marine engineering are carried on to a large extent. The harbour includes tidal basins, large wet docks, graving docks, and a slip.

Direct railway communication of Dundee with the south, established in 1878 by the erection of the Tay Bridge (single line), was interrupted by a disaster on the night of 28th December 1879, when, during a violent WSW. gale, the 13 large central spans of the bridge, with a passenger train containing 75 persons, fell into the river. The new bridge (double lines) is 10,700 feet, or fully 2 miles long, comprising an abutment at the south end, and 85 piers supporting girders. The rails at the south end are 83 ft. 6 in. above high water, and at the north end 26 ft. 6 in. Long spans of 245 feet occur near the middle of the river, where also the girders

are placed above the railway, to give the maximum room for shipping. The new bridge is parallel to the line of the old bridge, but 60 feet farther west, and the cutwaters of the old piers are still visible. It was opened for traffic in 1887, and cost £670,000, economy being effected by the utilisation of many of the girders of the old bridge. It has been proposed to use the piers of the old bridge to form a road-bridge connecting Fife with the North of Scotland. Pop. (1841) 63,732; (1871) 120,724; (1881) 140,239; (1901) 161,173; (1921) 165,004, including Broughty Ferry, annexed in 1913. Dundee sends two members to Parliament. Since 1889 it has been styled a city, and since 1892 its chief magistrate has been entitled Lord Provost. Among persons of note connected with Dundee may be mentioned Boece; 'Bluidy Mackenzie'; James Bowman Lindsay, linguist and electrical pioneer; Thomas Dick, the 'Christian philosopher'; Admiral Duncan; the 'saintly' McChyne; George Gillfillan; Thomas Eskine of Linlathen. On account of its geographical situation, its harbour and its castle, Dundee was frequently mentioned in early documents. Edward I. was here twice. Wallace is said to have taken the castle in 1297, and thereafter it was occupied by the Scots and English alternately until the decisive battle of Bannockburn. The Duke of Lancaster burned Dundee in 1385, and the Marquis of Montrose pillaged it in 1645. Charles II. lived here, after his coronation at Scone, in 1650. General Monk sacked and burned it in 1651, killing 1200 citizens and soldiers. Dundee was one of the first Scottish towns to adopt the Reformation. Wishart the martyr preached here during the plague of 1544.

Dundee, an inland town of Natal, 34 miles NE. of Ladysmith, has coal-mines and a battlefield (1899); pop. 4000.

Dundee, VISCOUNT. See GRAHAM (JOHN).

Dundonald, THOMAS COCHRANE, EARL OF, seaman, was the eldest son of Archibald, ninth earl (1749-1831), who beggared himself over chemical discoveries. Born at Annsfield, Lanarkshire, on 14th December 1775, he was destined for the army, but, after a desultory education, was permitted to enter the navy (1793). He served in the fords of Norway, for five years on the North American station, then in the Mediterranean, and in March 1800 received the command of a crazy little sloop of 14 *four-pounders* and 54 men. In a fifteen months' cruise he took or retook upwards of fifty privateers and merchantmen, 122 guns, and 334 prisoners; his most dashing achievement being the capture by boarding of a Spanish frigate of 32 heavy guns and 319 men, with a loss to himself of but 3 killed and 18 wounded. His own capture by three French line-of-battle ships followed shortly, his speedy exchange, his promotion to post-captain, a half-year of study at Edinburgh University, fifteen months on a 'collier,' protecting non-existent Orkney fisheries—at length, in February 1805, he returned to prize-taking, and in April came sailing into Plymouth Sound, with £75,000 of prize-money for his own share, and a tall gold candlestick at each mast-head.

The next four years were mainly spent in harassing the enemy's coasts—cutting out ships, blowing up semaphores and batteries, and in 1808, with 80 of his own men and as many Spaniards, defending for twelve days the almost untenable Fort Trinidad at Rosas. Meanwhile, in 1805 he had stood unsuccessfully for Honiton on 'patriotic' (no bribery) principles, but by rewarding his few supporters with double the current price, had secured a cheap victory at next year's election. In May 1807 Westminster returned him at the head of the poll; and at once proceeding, with more zeal than discre-

tion, to war against naval abuses, he was at once ordered off to the Mediterranean.

In April 1809 he was selected by the Admiralty for the hazardous service of burning the French fleet of fifteen sail (848 guns), then blockaded in Aix Roads by a stronger force under Lord Gambier. On the night of the 11th the huge boom guarding the entrance was shattered. Explosion vessels and fireships caused a panic. Daylight showed almost the whole French fleet aground—an easy prey. Gambier, however, was fourteen miles away. Cochrane's signals met with no response; consequently only four of the enemy's ships were destroyed. It was the last blow he was to strike for England.

He received the knighthood of the Bath; but to Gambier were voted the thanks of parliament, after 'a most honourable acquittal' by the friendly court-martial which ensued on Cochrane's protest against that vote. Thus discredited, put upon half-pay, Cochrane pursued his crusade against naval corruption, till in June 1814 he, the hero, the high-born, the Radical reformer, was placed in the dock as a fraudulent stock-jobber. A lying rumour of Napoleon's overthrow had sent up the funds; and he, with two others, was tied for propagating it, and selling out upwards of a million sterling with a gross profit of £10,000. Those two others—an uncle one—were certainly guilty. Lord Cochrane, by some held innocent, was sentenced to pay a fine of £1000, to suffer a year's imprisonment in the King's Bench, and to stand for an hour in the pillory. The last part of the sentence was remitted; but his name was struck off the navy list, and he was expelled from parliament, and formally degraded from his knighthood. Westminster re-elected him; and in March 1815 he broke out of gaol, and reappeared in the House, to be torn thence by tipstaves, lodged in the strong-room for the three months yet to run of his sentence, and next year mulcted anew in £100.

Weary of inactivity and of fruitless attempts at self-justification, in 1818 he once more girt on his sword, to rescue Peru and Chile from Spanish thralldom. As commander-in-chief of Chile's small, ill-equipped navy, he stormed with 300 men the fifteen strong forts of Valdivia (1819), and cut out a frigate from under the batteries of Callao (1820), in two and a half years making Chile mistress of her own waters, and her flag respected from Cape Horn to Panamá. He squabbled over his reward, as also over that (including the marquise of Maranhão) for his services, only less brilliant, on behalf of the infant empire of Brazil (1823-25).

For the cause of Greek independence he could do little or nothing, through lack of both ships and men (1827-28); so, returning to England, he devoted himself to the task of procuring his reinstatement in the navy. But it was not till May 1832, under the 'Sailor king' and Lord Grey's Whig administration, that a 'free pardon' was granted to the Earl of Dundonald—he had succeeded to the title ten months earlier—and that he was gazetted a rear-admiral. Restored to the honour of knighthood (1847), commander-in-chief on the North American and West Indian station (1848-51), and rear-admiral of the United Kingdom (1854), he died at Kensington, 31st October 1860, in his eighty-fifth year, and was buried in Westminster Abbey. He had married in 1812 Miss Katherine Corbet Barnes—a runaway Scottish marriage; she bore him Thomas, the eleventh earl (1814-85), and three other sons, of whom two entered the navy.

Much might be written of Lord Dundonald's inventions, his application of steam-power and the screw-propeller to war-ships; still more of his 'secret war-plan' to overwhelm fleets and fortresses

by sulphur fumes and the like. It was submitted to committees in 1812 and 1846, and condemned as too inhuman, though irresistible, infallible. But from the inventor one ever reverts to the tall, big, splendid sea-captain, brilliant, daring, cool, prompt, and sagacious, faultless afloat, though ashore out of his element. He equalled the old Elizabethan adventurers; he might, had Fate suffered it, have rivalled Nelson.

See the *Narrative of Services in the Liberation of Chili, Peru, and Brazil* (1859), nominally his own, and *Autobiography of a Seaman* (2 vols. 1860-61), which breaks off in 1814, and has been completed in the *Life* by the eleventh earl and H. R. Fox Bourne (2 vols. 1869); also the monograph in the 'Men of Action' series (1896) by the Hon. J. W. Fortescue; a book on the trial by J. B. Atlay (1898) in defence of the verdict; and Lord Ellenborough, *The Guilt of Lord Cochrane* (1914).

Dundrum Bay, an inlet of the Irish Sea, in County Down, is 13 miles wide across the entrance, and forms a long gentle curve cutting 5 miles into the land.

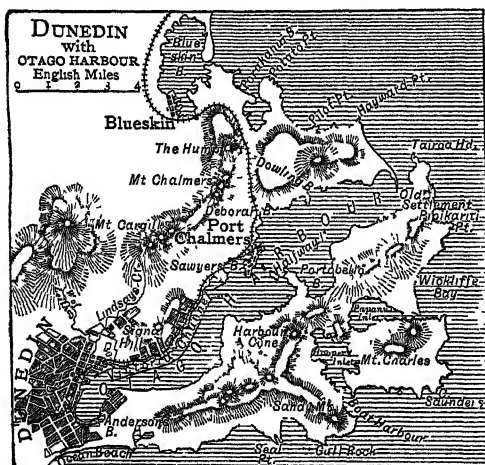

Dunecht. See CRAWFORD (EARL OF).

Dunedin, capital of the provincial district of Otago, and the most important commercial city in New Zealand, is situated at the head of Otago Harbour, on the east side of South Island, towards its southern extremity. It is 190 miles by sea from Lyttelton, and 150 miles from Invercargill, and 139 by rail. Since its foundation by an association of members of the Free Church of Scotland in 1848, the city has rapidly increased in importance; chiefly after the year 1861, when the discovery of extensive gold-fields in the neighbourhood caused a sudden increase of population. Dunedin is as well laid out as the hilly nature of its site will allow; it is well paved and lighted. It is supplied with water from the Water of Leith valley

with that of New Zealand, are flourishing institutions. The erection of an observatory in the Town Belt was sanctioned in 1920. There are several daily papers and numerous weeklies and monthlies. Woollens are manufactured and frozen meat prepared. The street tramways are mostly electric. Railways connect Dunedin with Christchurch to the north and Invercargill to the south. Dunedin has frequent communication with the other dominion ports, with Melbourne and the home country; and since the opening and deepening of the Victoria Channel from Port Chalmers, large steamers can approach the wharf. For purposes of defence, two batteries have been erected on the headlands at Ocean Beach, and a third on Otago Heads. The city was originally to have been named New Edinburgh, but on the suggestion of Dr William Chambers of Edinburgh its name was changed to Dunedin, the Celtic designation of the Scottish capital. Pop. of the city proper (1871) 14,857; (1881) 24,372; (1911) 41,529; (1921) 58,074, or with suburbs, which largely consist of adjacent boroughs, 72,255.

Dunes, from the same root as Dun (q.v.), 'a hill,' the name given to the sandhills or mounds which stretch more or less along the sea-coast of the Netherlands and parts of the north of France. In the *Battle of the Dunes*, fought near Dunkirk in 1658, Turenne defeated a Spanish army under Don John of Austria and the great Condé. See DOWNS and DRIFT; also DUNKIRK.

Dunfermline, a 'city' of Fife, the chief town of its western district, 16 miles N.W. of Edinburgh, and 20 E. by S. of Stirling. It stands on a long swelling ridge, 3 miles from and 300 feet above the Forth, and, backed by the Cleish Hills (1240 feet), presents a striking aspect from the south. It is a place of hoar antiquity, from 1057 till 1650 a frequent residence of Scotland's kings, and for more than two centuries their place of sepulture. Malcolm Canmore here founded in 1072 a priory, which David I. remodelled in 1124 as a Benedictine abbey. The nave alone of its church, Romanesque to Third Pointed in style, was spared at the Reformation, and now forms a stately vestibule to the New Abbey Church (1818-21), in building which Robert Bruce's grave was discovered. There are ruins of the 'frater-house' or refectory, of the 'pendent tower,' and of the royal palace (circa 1540); but of Malcolm's Tower only a shapeless fragment is left, and the 'Queen's House' (1600) was wholly demolished in 1797. Abbot Pitcairn's house is assigned to the 13th century. Little else survived the great fire of 1624. Quite modern are the Gothic corporation buildings (1876-79), with their peaked clock-tower; the spired county building (1807-50); St Margaret's Hall (1878), with a fine organ; the Carnegie Public Library (1881); the Carnegie Baths (1877-1905); the high school (1886-1915); and St Margaret's Roman Catholic Church. In 1903 Mr Andrew Carnegie made over £500,000, and in 1911 £250,000, to be held by trustees for behoof of his native town, to maintain Pittencrieff as a pleasure-ground, encourage horticulture, establish a theatre for first-class plays, provide education in music and the arts, and promote social well-being. The staple industry is damask linen-weaving, which dates from 1716. Dunfermline is the chief seat of the table-linen manufacture in the United Kingdom. Engineering works, iron-founding, &c. are also carried on; and in the neighbourhood are many collieries. Dunfermline was made a royal burgh in 1588. Its area was increased well-nigh fourfold in 1911 by the inclusion of Rosyth and intervening country. At Rosyth a tract of land extending over 3 miles on the north shore of the Firth of Forth, at St Margaret's Hope, opposite

and the Silverstream. For additional supplies it looks to the Waipori, whose falls furnish electric power. Dunedin is the seat of an Anglican and a Roman Catholic bishop. There are many handsome churches and buildings; the Bank of New Zealand, completed in 1882, is one of the finest in the city. Other edifices are the post-office, hospital, government buildings, mechanics' institute, lunatic asylum, &c.; and the inhabitants of the city possess places of recreation in the Botanical Gardens and the grounds of the Acclimatisation Society. The theatre was burned down in 1875, and rebuilt. There is a carriage-drive through the reserve called the Town Belt, which encircles the city, and a fine racecourse, near Ocean Beach, 2 miles distant. The high school and the university, which is affiliated

(South Queensferry, and just above the Forth Bridge, was acquired by the government in 1903, and a naval base was constructed. Docks, roads, and dwellings grew rapidly during the Great War, and Dunfermline's population was greatly increased. In 1925 it was decided to close the naval base. The ruined 16th-century castle of Rosyth, a rock-island connected with the shore by a causeway, was said, by baseless tradition, to have been the birthplace of Oliver Cromwell's mother. Population of Dunfermline (1801) 5484; (1881) 17,085; (1901) 25,250; (1921) 39,886. The parliamentary burgh unites (since 1918) with Cowdenbeath, Inverkeithing, and Lochgelly to return one member. For Dunfermline's worthies, reference may be made to our own articles on St Margaret, James I., Robert Henrysoun, Charles I., Ralph Erskine, Sir Noel Paton, and Mr Andrew Carnegie.

Dungannon, a municipal borough in County Tyrone, 40 miles W. of Belfast by rail, and 8 W. of Lough Neagh. It has manufactures of linen and coarse earthenware; and in the vicinity are the largest lime-quarries and collieries in Ulster. Pop. (1851) 3835; (1881) 4081; (1911) 3830. Till 1885 it returned one member to parliament. Dungannon was the chief seat of the O'Neils till 1607. Its castle was destroyed in 1641.

Dungans. See ZUNGARIA.

Dungarvan, a seaport of County Waterford, 141 miles SW. of Dublin by rail. Population 5000, chiefly engaged in hake, cod, herring, and other fisheries. The exports are grain, butter, cattle, and fish. Dungarvan has the remains of an Augustinian abbey, founded in the 7th century by St Garvan. It has besides the remains of walls built by King John, who also built the castle. Till 1885 Dungarvan returned one member to parliament. Dungarvan Bay is 3 miles wide, about the same in length, and one to five fathoms deep.

Dung-beetle, a name given to a number of lamellicorn beetles (in the sub-families Copiophaga and Arenicolæ), which live in great part on the dung of quadrupeds. One of the commonest, the Black Dor (*Geotrupes stercorarius*), is interesting in many

Dung-beetle
(*Geotrupes stercorarius*).

ways, for its elaborate burrows and stores under cow-dung and the like, for the 'stridulating' noises made by both sexes by rubbing part of the abdomen against a ridge on the hindmost leg, for the little ticks (*Gamasus coleopterorum*) by which it is generally infested, and for its association with another nearly-related beetle (*Aphodius porcus*) which finds its way into the burrow, eats the *Geotrupes*' eggs, and lays its own in the liberal supply of food thus thievesly appropriated. Among the other British species of *Geotrupes*, *G. typhaeus*, with three horns on the front of the thorax in the males, is found especially on heaths where there are sheep. The sacred beetle or Scarabee (q.v.) (*Ateuchus* or *Scarabeus sacer*) is a well-known dung-beetle. They roll pellets of dung along with great industry, and often appear unable to resist stealing them from one another. A related form (*Sisyphus schafferi*), the pill-rolling beetle, is said to lay its eggs inside the pellets of dung, and both sexes are described as taking part in rolling these to a place of safety. The scarabee used also to be credited with laying eggs within the pellets, but this appears

to be erroneous. *Copris lunaris* is a common European dung-beetle, which makes burrows and stores dung for the larvæ. There are many other forms. The Dor and others feign death, stretching out their legs in rigid epileptic-like fashion. Crows and other birds are said to prefer them alive.

Dungeness, a headland on the south coast of Kent, 10½ miles SE. of Rye, with a lighthouse.

Dungeon. See DONJON.

Dunite, so named from Dun Mountain, near Nelson, New Zealand, is a crystalline rock consisting almost entirely of olivine. A black granular mineral akin to chromite and picotite also occurs in it. The olivine may be altered into serpentine.

Dunkeld, a town of Perthshire, 16 miles NNW. of Perth. It lies in a deep romantic hollow, on the great east pass (of Birnam, q.v.) to the Highlands, on the left bank of the Tay, which here is spanned by Telford's handsome bridge (1805-9). It is environed by dark-wooded and craggy mountains. Dunkeld is a place of great antiquity, and a Culdee church was founded here about 815. In 1107 Alexander I. revived the bishopric, one of whose holders was Gawin Douglas (1474-1522), translator of Virgil's *Æneid*. The place was successfully held by a small Cameronian regiment, under Cleland, against 5000 Highlanders, 21st August 1689. The cathedral, mainly in Pointed style, was built between 1318 and 1501, and comprises nave, choir, chapter-house, and tower. At the Reformation it was unroofed, but the choir has been renovated, and is now the parish church. Of two or three ancient monuments, the most interesting is one to the Wolf of Badenoch (Alexander Stewart, Earl of Buchan, who died in 1394). The Duke of Athole's grounds, unsurpassed in Scotland for extent and beauty, lie on the west and north of Dunkeld, and include Craigvinean and Craig-y-Barns; 50 miles of walks, and 30 miles of drives; falls of the Bran (upper one 80 feet), near Ossian's Hall at the Rumbling Bridge; and wide larch-woods, including what are claimed to be the first two larches planted in Britain (in 1738), although the point has been disputed.

Dunkers. See TUNKERS.

Dunkery Beacon. See EXMOOR.

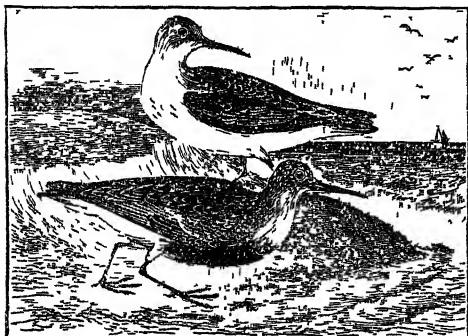

Dunkirk, or DUNKERQUE, the most northerly seaport of France, on the Strait of Dover, in the department of Nord, 161 miles N. of Paris, and 67 W. of Ghent. It is a very strong place, as well from fortification works, as from the ease with which the surrounding country can all be laid under water. As a seaport it is one of the most important in France; and great harbour works have been sanctioned and in part carried out under the laws of 1879, 1903, and 1919. The town itself is well built and cleanly, Flemish rather than French; its principal features, the Gothic church of St Eloi with a handsome though rather incongruous Corinthian portico, the fine detached belfry (196 feet), and the statue of Jean Barth (q.v.). Dunkirk has manufactures of linen, jute, hemp, fishing-lines, oils, soap, beet-root sugar, &c. Forming as it does the outlet for the great manufacturing department of Nord, its trade by sea is very extensive. It is an important market for nitrates, sugar, and wool. Its cod and herring fisheries are actively prosecuted. Pop. (1872) 34,342; (1886) 33,004; (1901) 40,329; (1921) 34,748.

Dunkirk is said to owe its origin to the church built by St Eloi in the 7th century, in the midst of the dreary sandhills or dunes, and hence its name, 'Church of the Dunes.' It was burned by the English in 1388, taken by them under Oliver Cromwell in 1658, but sold to Louis XIV. by Charles II. for 5,000,000 francs in 1662. By the

treaty of Utrecht in 1713, the French were compelled to destroy the fortifications of Dunkirk, which were again restored, however, in 1783. In 1793 the Duke of York laid siege to Dunkirk, but was forced to retire, with severe loss.

Dunkirk, a port of entry of New York, on Lake Erie, 40 miles SW. of Buffalo by rail, with a commodious harbour and a busy lake traffic. The terminus of a division of the Erie Railroad, Dunkirk contains large workshops and warehouses of the company, besides extensive locomotive works, lumber-mills and several ironworks. Pop. 19,000.

Dunlin (*Pelidna alpina* or *cinclus*), one of the Sandpipers (q.v.), a common British shore-bird, occurring in great flocks. It generally breeds further north, and is widely distributed in Europe. The plumage varies considerably; in winter it is ashen-gray above and white beneath; in summer there is much less uniformity, more brown and black, and a black horseshoe band on the breast.

Dunlin, Summer and Winter Plumage.

It exhibits great activity in running about, searching and probing for its food. Another species (*P. temminckii*) is common in Europe and North America. The Curlew Sandpiper (*P. subarquatus*), with a more curved bill and deep-red breast, also occurs on European and British shores. These three species are sometimes included in the genus *Tringa*, along with the Knot (*T. canutus*) and other Sandpipers (q.v.). 'When flying in great autumnal flocks, the aerial movements of the dunlin are extremely beautiful, each individual of the vast assemblage yielding so instantaneously to the same impulsion as to exhibit alternately the upper and the under surface of the body, so that we have for a time a living moving cloud of dusky brown, and then a brilliant flash of snowy whiteness.'

Dunlop, JOHN BOYD (1840-1921), inventor, was born at Dregghorn, Ayrshire, and educated at Irvine and Edinburgh. He practised as a veterinary surgeon in Belfast, and in later life lived in Dublin. His principal invention was the pneumatic tire, for which he opened a factory in Dublin, afterwards removed to Coventry.

Dunmore, a borough of Pennsylvania, adjoining Scranton, has silk, woollen, sparking-plug and stove works, and coal-mines; pop. 20,000.

Dunmow, GREAT, a small market-town of Essex, on the Chelmer, 11 miles NNW. of Chelmsford, and 32 NNE. of London.—At Little Dunmow, 2 miles ESE., are remains of a stately Augustinian priory, founded in 1104. The Dunmow Flitch of Bacon (see *Piers Plowman*, passus x.) was a prize instituted in 1244, by Robert Fitzwalter, on the condition 'that whatever married couple will go to the priory, and kneeling on two sharp-pointed

stones, will swear that they have not quarrelled nor repented of their marriage within a year and a day after its celebration, shall receive a flitch of bacon.' The first recorded award was in 1445, two hundred years after it had been instituted. After 1751, up to which date only five presentations had taken place, the flitch was not again claimed till 1855; since then many awards have been made. See W. Andrews, *History of the Dunmow Flitch* (1877).

Dunnage, on shipboard, is a name applied to miscellaneous fagots, boughs, bamboos, odd mats or sails, and loose wood of any kind, laid in the bottom of the hold to keep the cargo out of the bilge-water; or wedged between parts of the cargo to keep them steady.

Dunnottar Castle, the ancient seat, now in ruins, of the Keiths, the Earls Marischal of Scotland, on the Kincardineshire coast, $\frac{1}{2}$ miles S. of Stonehaven. It occupies the top of a rock $\frac{1}{2}$ acres in extent, and 160 feet high, overhanging the sea, with a deep though dry chasm between it and the mainland, and it is approached by a steep winding path. The area is surrounded by a wall, and covered with dismantled buildings of very various ages, the oldest the square tower and the chapel. Blind Harry records a fabulous story that Wallace in 1296 took the rock, and buried the castle together with the kirk and 4000 Englishmen. During the Commonwealth, the Regalia of Scotland were hid in the castle from the republican army, and before the garrison surrendered to Cromwell's troops in 1651, the Regalia were carried out, according to one account, by Mrs Granger, wife of the minister of Kinnell, a neighbouring parish, and buried under the flagstones of its church, where they lay in safety till the Restoration. Rival claims upon the king's gratitude then involved the Keiths, the Ogilvies of Barra (the family of the governor), and the Grangers in bitter feuds, in which none of the royalists showed up well. For three months in 1685 no fewer than 167 Covenanters were confined with the most barbarous cruelty in the 'Whigs' Vault.' Dunnottar Castle was dismantled after the rebellion of 1715, on the attainder of the last Earl Marischal.

Dunois, JEAN, called the Bastard of Orleans, Count of Dunois and Longueville, one of the most brilliant soldiers that France ever produced, was born in Paris, 23d November 1402, the natural son of Louis, Duke of Orleans, brother of Charles VI., and was brought up in the house of that prince along with his legitimate children. His first important military achievement was the overthrow of the English at Montargis (1427). He next threw himself into Orleans with a small body of men, and bravely defended the place till the arrival of the famous Joan of Arc, whose religious enthusiasm combined with the valour of Dunois restored the drooping spirits of the French, and compelled the English to raise the siege. This was the turning-point in the fortunes of the French nation. In 1429 Dunois and the Maid of Orleans won the battle of Patay, after which he marched, with a small body of men, through the provinces then overrun by the English, and took the fortified towns. The capture and death of Joan of Arc arrested for a moment the progress of the French arms, but the heroism of Dunois was irresistible. He took Chartres, the key of Paris, forced Bedford to raise the siege of Lagny, chased the enemy from Paris, and within a very short period deprived them of all their French conquests except Normandy and Guienne. In 1448-50 he drove the English from Normandy, and in 1455 he had swept them from Guienne also, and permanently secured the freedom of France from all external pressure. For his par-

ticipation in the league of the nobles against Louis XI. he was deprived of all his offices and possessions, which were, however, restored to him under the treaty of Confians (1465). He died 24th November 1468. There is no name so popular in France as that of Dunois; there is no hero so national; he laboured twenty-five years for the deliverance of his country, and this *alone*—his sword was never unsheathed, except against the English. He never had a force under him which could enable him to win a victory that might balance Agincourt or Crécy, but the multitude and constancy of his petty successes served the cause of France more effectively than greater and more dear-bought victories would have done.

Dunoon, a favourite watering-place of Argyllshire, extending, with Hunter's Quay and Kinn, 3 miles along the west shore of the Firth of Clyde, 7 miles W. of Greenock. The seat for centuries of a castle of the Stewarts, in 1563 it received a visit from Queen Mary, and in 1643 was the place where thirty-six Lamonts were cruelly hanged by the Campbells. But the present well-built town has wholly arisen since 1822—with its baronial burgh buildings, its piers, its esplanade, its half-dozen churches, the Convalescent Homes (1869), and the statue (1896) to Burns's Highland Mary, born here. Pop. (1841) 1296; (1911) 6859; (1921) 14,735. The apparent increase is due to the 1921 census being taken in the holiday season.

Dunraven, WINDHAM THOMAS WYNDHAM-QUIN, Earl of, born at Adare Manor, Limerick, 12th February 1841, studied at Christ Church, Oxford, served in the 1st Life Guards (1865-67), acted as *Daily Telegraph* correspondent in the Abyssinian expedition and Franco-German war, and succeeded his father as 4th Earl in 1871. He was Under-secretary for the Colonies (1885-87); advocated 'devolution' as a solution of the Irish question; competed for the America Cup (1893, 1895); and wrote on travel, sport, and politics.

Duns, a police-burgh of Berwickshire, 44 miles ESE. of Edinburgh, has superseded Greenlaw as county town, partly in 1853, now wholly, and has a town-hall, county buildings, and a corn exchange. Thomas Boston was a native; and on round, turfed Duns Law, which rises 700 feet above the sea, and 280 above the town, Leslie encamped with the Covenanting host in 1639. The town Dunse was altered in 1882 to Duns, the spelling till 1740. Pop. (1834) 2656; (1881) 2437; (1921) 1868.

Dunsany, EDWARD JOHN MORETON DRAX PLUNKETT, 18th Baron, was born in London 24th July 1878, fought in the South African and Great Wars, stood for West Wilts (1906) as a Conservative, and wrote many volumes of plays and prose tales.

Dunsinane, one of the Sidlaw Hills in Perthshire, 1012 feet high, $\frac{3}{4}$ miles NE. of Perth. On its top are remains of a prehistoric fortress—'Macbeth's Castle.'

Dunsink, a hill 4 miles NW. of Dublin, the site of the observatory of Trinity College.

Duns Scotus, JOHANNES, was one of the most influential of the medieval schoolmen. Little is known of his history. His name alone seems to be the chief reason for the different conjectures as to his birthplace, which is variously given as Dunstane, a village in Northumberland, Dun (now Down) in the north of Ireland, and Duns in Berwickshire. He was probably born about 1265 A.D., or, according to others, about 1274. While still young, he is said to have entered the Franciscan order, studied at Merton College, Oxford, and lectured there on philosophy and theology. The reports of the number of his auditors, and that

30,000 students then thronged to Oxford, may be taken as testifying in an exaggerated way to the popularity of his instructions. In 1304 he was transferred to Paris, then the intellectual centre of the world, and in 1308 to Cologne, where he died, in November of the same year, at the age of forty-three, or, according to the other account, thirty-four. His works consist chiefly of commentaries on the Bible, on Aristotle, and on the *Sentences* of Peter Lombard. The first are not contained in the collected edition (edited by Luke Wadding, Lyons, 1639). The last occupy seven out of its twelve vols. folio (vols. v.-x. called *Opus Oxoniense*, vol. xi. called *Opus Parisense*—the latter edited from students' note-books, but containing the author's latest views).

Duns Scotus was at once the critic of preceding scholasticism and the founder of a new type of thought. The great schoolmen of the 13th century, especially Albertus Magnus and Thomas Aquinas, had systematised and defended the Christian theology by means of the forms and doctrines of the philosophy of Aristotle. In this way philosophy became the handmaid of religion, and the authority of Aristotle was recognised by orthodox teachers. On certain points indeed—such as the eternity of matter and of the world—his theological position compelled Aquinas to diverge from Aristotle. But the disagreement of Duns Scotus went much deeper. He contended that Aquinas was wrong in subordinating the practical to the theoretical, and seeking in speculation instead of in practice for the foundation of Christian theology. This contention struck at the root of the whole Aristotelico-Christian philosophy. Theology, he holds, rests on faith, and faith is not speculative but practical—an act of will. Will is the moving principle of intellect, not intellect the basis of will. 'Will,' he says, 'is the mover in the whole kingdom of mind, and all things are subject to it.' The whole apparatus of proofs by which Aquinas had built up a system of Christian theology is subjected by Duns Scotus to a searching criticism, conducted with consummate dialectical skill, and abounding in refined distinctions, which gained for him the title of 'Doctor Subtilis.' In his own system Duns Scotus maintained a strict theological orthodoxy. He carried on a zealous controversy against the Dominicans (the order to which Aquinas belonged) in defence of the doctrine of the Immaculate Conception, a doctrine which gradually gained ground in the church, until in 1854 it was finally declared to be a necessary part of Catholic faith. In philosophy he was influenced not only by Aristotle, but also by Neoplatonic doctrines which reached him to a large extent through the *Fons Vitæ* of the Jewish Ibn Gebirol (Avicbron, q.v.). By this influence in particular, his mode of applying the realist doctrine of universals, and his explanation of the nature of things, were much modified. His psychological doctrine of the supremacy of will over intellect led to his treatment of morality as depending on the mere will of the Deity. The good is good, he held, because God commands it. See AQUINAS, FRANCISCANS.

The controversies between Thomists and Scotists were continued long after the deaths of their leaders. Among notable Scotists were Nicholas de Lyra (1340) and Petrus de Aquila (1345); and William Ockham, the Nominalist, was originally a disciple of Scotus, the apostle of Realism. See SCHOLASTICISM, NOMINALISM, REALISM. At a later period, when the followers of Duns Scotus or *Dunsmen* opposed the new classical studies, the name *dunce* came to be used contemptuously for an opponent of learning, an ignoramus.

For a further account of the views of Duns Scotus, the 'Doctor Subtilis' of the schools, see K. Werner's

J. Duns Scotus (Vienna, 1881); E. Pluzanski's *Essai sur la Philosophie de Duns Scot* (Paris, 1887); the histories of philosophy of Ritter, Erdmann, and Ueberweg; Prantl's *Geschichte der Logik*; and Hauréau's *Philosophie Scolastique*.

Dunstable, a town in the south of Bedfordshire, at the east base of the Chiltern chalk-hills or Dunstable Downs, 34 miles NW. of London. An old-fashioned, brick-built place, with two main streets crossing at right angles, it has a fine priory church, partly Norman, which since 1865 has undergone restoration. In 1110 this Augustinian priory was the scene of the earliest miracle play on record, so that Dunstable claims to be the birth-place of the English drama. It has also an ancient celebrity for larks and for straw-plait, which still is the staple industry. The grammar-school (1715) was rebuilt in 1888. Dunstable, which stood at the intersection of Watling and Icknield Streets, was the site of an Eleanor Cross (demolished 1643), and the scene of Cranmer's annulment of Queen Catharine's marriage. It was made a municipal borough in 1864. Pop. 9000.

Dunstable, or DUNSTAPLE, JOHN, 'astronomer, mathematician, musician and what not,' is generally held to have been born at Dunstable in Bedfordshire, but he may have been a native of Hertfordshire. Little is known of his life. He died 24th December 1453. He enjoyed a European reputation—short-lived but apparently fully deserved—as one of the earliest musicians who laid the foundations of the great schools of the 16th century. Misreading of a reference in the *Proportionale* of Johannes Tinctoris (1445–1511) has led some absurdly to claim for him the invention of counterpoint. He is, however, by far the greatest English musician of the first half of the 15th century. Some examples of his music survive.

Dunstaffnage Castle. See ETRIVE (LOCH).

Dunstan, St, Archbishop of Canterbury (960–988), was the son of a West Saxon noble, and was born near Glastonbury. There at the abbey he was educated by some resident Irish scholars, and while still a boy he lived some time at the court of Athelstan, but seems to have been unpopular with his young companions, who ill-used him and procured his banishment on the charge of practising unlawful arts. After a stay at Winchester with his kinsman Bishop Ælfheah, to whom he made his profession as a monk, he retired to Glastonbury, where he gave himself entirely to study and to music. It was at this time of his life that he built himself a cell 5 feet long by 2½ feet broad, where he retired to pray, and where heavenly visions were vouchsafed to him. Here also he worked in metals, and it was while labouring at his forge that his famous temptation by the devil took place, which he ended by promptly seizing the fiend by the nose with his red-hot tongs. The accession of Athelstan's brother, Edmund, recalled him to court, from which he was soon driven—most likely to East Anglia—only to be soon restored to the king's favour, and appointed Abbot of Glastonbury (945). Here he began a great work of reformation, and soon his abbey grew to be a great school and a centre of religious influence. At the same time he became the treasurer, and in harmony with the queen-mother Eadgifu, the chief adviser of the young king, whose death at Frome in 955 led to the accession of Edwy and the fall of Dunstan's power before the influence of the young queen Ælfgifu, her mother Æthelgifu, and the leaders of the West Saxon party. He took refuge in Flanders, where Arnulf I., by his mother grandson of Alfred, received him kindly. At Ghent he first saw the strict Benedictine discipline which he was to introduce into England. Two years later he was recalled

by Edgar, who had become, through a rebellion of the Mercians and Northumbrians, king of the country north of the Thames, and created Bishop of Worcester, to which was added a little later the see of London. In 959 Edwy's death made Edgar king of the whole country. One of his first acts was to annul Brithelm's appointment to the see of Canterbury, and, by advice of the witan, to appoint Dunstan in his room. The wise measures that made Edgar's reign so peaceful and prosperous was in great part due to the counsels of Dunstan. It was his policy to weld the Danes and the English into one nation, and his wise and liberal measures to this end were rewarded by the gratitude of the Danes. It is significant that Cnut in 1017 ordered the universal observance of St Dunstan's mass-day. With Oswald, Archbishop of York, he solemnly crowned Edgar at Bath, on Whit-sunday 973—a formal declaration of the unity of the kingdom. He was active in building churches, and sympathised heartily with the establishment of monastic life on the rigorous Benedictine rule. The secular clerks were turned out of the monasteries, but clerical celibacy was not made compulsory in any more direct manner than that a married priest lost the privilege of his order. Dunstan laboured to elevate the lives of the clergy, and make them the real teachers of the people in secular learning and skill in handicrafts, as well as in moral and religion. Himself a man of the severest purity of life, he was absolutely fearless in insisting upon the penances which he laid upon the great, but showed his wisdom in turning these into practical channels. He raised the social status of the clergy, and made obligatory the payment of tithes by landowners, while he did not entirely surrender the liberties of the church to Rome. Edgar's death in 975 opened up anew the struggle between the seculars and the monks, but Dunstan declared for Edward, elder son of the late king, and crowned him at Winchester. His triumph was complete, and the fall of the floor of the council-room at Caine (977), in which only his enemies were killed or injured, seemed to some like a divine judgment in his favour. On Edward's murder in 978, the two archbishops crowned Ethelred king, whose hostility put an end to the great churchman's political career. Dunstan spent his later years at Canterbury, busily employed in the affairs of the church, in study, in private prayer, and the services of the church, varied with the handicraft of his earlier days. The memory of his gentleness and patience long survived him. He died in 988, and was buried near the altar of his church. His day is 19th May. See Bishop Stubbs's *Memorials of St Dunstan* (1875) in the Rolls Series, a collection of six early biographies of the saint; also J. Armitage Robinson's *The Times of Saint Dunstan* (1923; Ford Lectures, Oxford, 1922).

Dunstanburgh Castle, a picturesque ruin on the basaltic sea-cliffs of the Northumbrian coast, 8 miles NE. of Alnwick. Crystals of quartz found here are called Dunstanburgh diamonds and amethysts.

Dunton, JOHN, bookseller, was born in 1630. Refusing to make the fourth in a direct line of clergymen, he was apprenticed to a London bookseller at fourteen, and managed to complete his time, and to acquire much varied knowledge, in spite of love, politics, and the thousand distractions incidental to a mind of such exceptional flightiness as his. He took a shop, married happily, made some lucky ventures, but was foolish enough to become security for the debts of some of his relatives, and had in consequence to fight a hard battle with financial troubles. He paid a visit to America, afterwards to Holland and Cologne,

settled somehow with his creditors, and kept shop for ten years with fair prosperity, his *Athenian Gazette* being for a while especially successful. In 1692 he succeeded to a cousin's property, and became a freeman of the Stationers' Company. He married a second time unhappily, and under the real and imaginary troubles of his later years, his mind seems to have crossed the line between crackbrained flightiness and sheer lunacy. His extraordinary book, *Life and Errors of John Dunton*, appeared in 1705. Thereafter he wrote numerous papers and pamphlets, and died in 1733.

Dunwich, on the cliffs of the Suffolk coast, $4\frac{1}{2}$ miles S. of Southwold, made the episcopal see of the Southfolk c. 630, became a large and important place. Its ancient buildings have been swept away by the sea; in 1350 more than 400 were washed away at once. The remaining fragment of the church tower was removed in 1923 to a safer site. Dunwich sent two members to parliament till 1832, and till 1883 was a municipal borough.

Duodecimal Scale (Lat. *duodecim*, 'twelve') is the name given to the division of unity into twelve equal parts, as when the foot is divided into 12 inches, and the inch into 12 lines; or the pound is divided into 12 ounces. This plan of counting has some advantages, as 12 admits of so many divisions into equal parts—viz. by 2, 3, 4, and 6. But the decimal scale, or division into ten equal parts, is now universally recognised as preferable, from its coinciding with our decimal system of notation.—**DUODECIMALS**, a method of calculating the area of a rectangle when the length and breadth are stated in feet and inches.

Duodenum, the first portion of the small intestine, next to the pyloric end of the stomach. See DIGESTION.

Dupanloup, FÉLIX ANTOINE PHILIBERT, Bishop of Orleans, was born at St Félix, near Annecy in Savoy, 3d January 1802. He received priest's orders in 1825, and, after acting as tutor to the young Orleans princes, was appointed in 1837 superior of the Little Seminary in Paris. Here he had an opportunity of carrying out still further his favourite views as to education; and he remained fond of teaching even after his appointment as Bishop of Orleans in 1849. During the reign of Louis-Philippe he strove earnestly in behalf of freedom of education, and to secure tolerance for the Jesuits. The publication of the papal Encyclical and *Syllabus* in 1864 called forth from him *La Convention du 15 Septembre et l'Encyclique du 8 Décembre*, a pamphlet of which 34 editions had to be issued within a few weeks. In this little book, the eloquent bishop defends the temporal authority of the pope. Nevertheless he received with great reserve the first intimations of the pope's intention to summon a council for the purpose of proclaiming the dogma of papal infallibility; and after his arrival at Rome, to take part in the deliberations of the council, he protested openly against the doctrine; and when he found that all opposition was in vain, he left the Holy City on the evening prior to the promulgation of the decree by the council. Yet, once the dogma was published, he submitted to the will of the church, and signified his acceptance of it. In 1871 the bishop was elected deputy for Orleans to the new National Assembly, the only bishop who sat in it. From this time onwards to the date of his death, at Lacombe, near Lancey (Isère), 11th October 1878, he struggled manfully against the attacks which were being constantly made upon the church both in the Assembly and outside of it. He became a senator in 1876, and in 1854 a member of the Academy, but resigned his fanteuil on the election of Littré. His writings are numerous.

See the *Lives* by Lagrange (trans. by Lady Herbert, 1885) and by Faguet (1913).

Dupin, FRANÇOIS-PIERRE-CHARLES, BARON, was born in 1784, and served as an engineer under the Empire. In 1816–19 he made several visits to England and Ireland; the results of his investigations appeared in his chief work, *Voyages dans la Grande Bretagne* (6 vols. Paris, 1820–24). He was made a baron in 1824, a peer in 1837, and filled several posts, which he resigned in 1852. He died in 1873. His elder brother, André (1783–1865), was a statesman and lawyer, the author of several important works on legal subjects, and 4 vols. of memoirs (1855–61).

Dupleix, JOSEPH FRANÇOIS, the celebrated governor of the French Indies, was born 1st January 1697, at Landrecies. At the age of eighteen he was sent to sea on board an East Indiaman, and in 1720 his father, a farmer-general of taxes, who was a shareholder in the French East India Company, had him appointed to a seat in the Council at Pondicherry, where he combined admirable official work with the amassing of wealth by legitimate trade speculations. Ten years later he became superintendent at Chandernagore in Bengal. The remarkable success of his administration here led to his being appointed, in 1741, governor-general of all the French Indies, with the title of Nawab. He now successfully pursued that policy of patient skilful diplomacy among the Indian princes, which at one time made the Carnatic almost a French province. His ostentation, the increase and discipline of his army, and his improvements in the defences of Pondicherry had already begun to alarm the English Company, when war broke out in Europe between France and England (1742). La Bourdonnais, the governor of Bourbon and the Isle of France, having sailed with a powerful squadron to the Coromandel coast, took Madras, but, without authority, and in consideration of a bribe of £40,000 from the English Company, agreed to restore it to the English on payment of a ransom. This Dupleix refused to accede to, and violent disputes followed between the two governors, the result of which was that La Bourdonnais was recalled. Several brilliant engagements planned by Dupleix took place between the French garrison and the troops of the Nawab of the Carnatic, who endeavoured to take possession of Madras, but was precipitately forced to raise the siege. An attack on the English at Fort St David failed, but Dupleix's science and courage were eminently displayed in the defence of Pondicherry, which Admiral Boscawen in vain attacked for five weeks, with an apparently overwhelming force, but was forced to retire discomfited, although the defence was conducted by a civilian, unsupported by a single general of repute. The ambitious mind of Dupleix had long formed the project of founding a French empire in India on the ruins of the Mogul monarchy, and with this purpose he mixed ingeniously in all the intrigues of Southern and Central India, made himself master of the court of Hyderabad, and placed a creature of his own on the throne of the Carnatic, while he impressed the native imagination by adopting all the pomp and splendour of the Oriental. His military designs, however, able as they were, were frustrated by the energy and military genius of Clive and Lawrence; but the struggle continued until 1754, in which year Dupleix was recalled by Louis XV., who had patched up an agreement with England on the subject of the rival Indian companies, which was embodied in the futile Peace of Pondicherry, 1755. La Bourdonnais had actively laboured to disparage Dupleix, and the French Company had not seconded their governor's ambi-

tious schemes, and refused to reimburse him for the vast sums he had spent out of his private fortune in carrying on the war. He died in poverty and neglect in 1763. See Hamont, *Dupleix d'après sa Correspondance inédite*; Cultru, *Dupleix, ses plans politiques, sa disgrâce* (1901); Alfred Martineau, *Dupleix et l'Inde française* (1920 et seq.); and Lives by Malleon (1890), Guérin (1908), and Biddulph (1910).

Duplicand, a double payment of feu-duty on certain occasions. See CASUALTIES OF SUPERIORITY, FEU.

Duplication. See DOUBLING THE CUBE.

Duplicidentata ('double-toothed'), a sub-order of Rodentia (q.v.), distinguished from the Simplicidentata by the possession of a second pair of upper incisors. It includes the hares and rabbits, and the tailless hares or pikas.

Düppel, or DYBBÖL, a village of Danish Slesvig, 15 miles NE. of Flensburg. In 1849 it was stormed by the Germans, supporting the Sleswick-Holsteiners against the Danes; and in 1864, by the Prussians, after a month's bombardment.

Dupré, JULES, landscape-painter, was born at Nantes in 1812, and died at Paris 8th October 1889. His aim was to produce a *paysage intime* rather than a pretty picture, and was specially skilful in the management of the light and tone.

Dupuis, CHARLES FRANÇOIS, *savant*, was born in 1742, and already in 1766 was called to a chair of Rhetoric in Paris, when he was led to explain mythology by means of astronomy. A work on this subject appeared in 1781. He was now appointed professor of Eloquence in the Collège de France, member of the Académie des Inscriptions, and during the Revolution, a member of the Convention, next of the Council of Five Hundred, and afterwards of the legislative body, of which he became president. He died in 1809. His great work, *Origine de tous les Cultes, ou Religion Universelle* (1795, 10 vols.), was an extension of the memoir of 1781, and no doubt originated the famous commission afterwards appointed by Napoleon to explore Upper Egypt, which Dupuis had pointed out as the general source of southern mythology.

Dupuytren, GUILLAUME, BARON, a French surgeon, was born in 1777, and in 1812 was appointed professor of Clinical Surgery and surgeon-in-chief to the Hôtel-Dieu in Paris. He died in 1835. Keen in diagnosis, and firm of nerve, he invented many ingenious modes of operation and various surgical instruments.

Duquesne, a borough of Pennsylvania adjoining McKeesport, has steel-works and blast-furnaces; pop. 19,000.

Duquesne, ABRAHAM, MARQUIS, French naval officer, was born at Dieppe in 1610, and distinguished himself in 1637-43 in the war with Spain. During Louis XIV.'s minority he entered the Swedish service, and rose to the rank of vice-admiral. Returning to France, he reduced to submission Bordeaux, which had declared for the Fronde. He was successful in several engagements with De Ruyter and Van Tromp in 1672-73, and defeated the united fleets of Spain and Holland off Sicily in 1676, in an action in which De Ruyter fell. On the revocation of the Edict of Nantes, Duquesne was made the only Protestant excepted from the general decree of banishment. He died 2d February 1688. See Jal, *Duquesne* (1872); Laughton, *Studies in Naval History* (1887).

Dura Den, between Cupar and St Andrews, in Fife, a small glen through which runs a tributary of the Eden, famous for the numerous and beautifully preserved fossil fish entombed in its yellow sandstone (Upper Old Red Sandstone).

Dura Mater, the outermost membrane of the brain and spinal column, distinguished from the arachnoid and the pia mater. See BRAIN, NERVOUS SYSTEM.

Duramen, or HEART-WOOD, in Botany, the inner and fully ripened wood of dicotyledonous trees. The division is often very marked between the *duramen* and the *Alburnum* (q.v.), or sap-wood, the former being more dense and compact, and also frequently of a darker colour, as most notably in ebony. As timber it is much more valuable and durable than the alburnum; hence this distinction is as well known to the carpenter or cabinetmaker as to the botanist. See TIMBER, WOOD.

Durán, AGUSTÍN, Spanish poet and critic, born at Madrid in 1789, studied law at Seville, and became an advocate. He was employed in the education office, the board of press censorship, and the national library. He died in 1862. He collected and edited old ballads (*Romancero General*) and plays.

Duran, ÉMILE AUGUSTE CAROLUS (1837-1917), painter, was born at Lille. In 1853 he began to study in Paris; in 1861 he went to Rome; and afterwards spent some time in Spain, where his style was powerfully influenced by Velasquez. For 'L'Assassiné' (1866) he gained his first medal; and in 1878 he exhibited his design—'Gloria Mariæ Medicis'—for a ceiling in the Luxembourg. Duran, however, is most widely known by portraiture, which is distinguished by great vigour, force of colouring, and power of direct realism. Among his portraits may be named those of Émile Girardin and Pasteur, and an equestrian one of Mlle. Croizette. He was also a most successful teacher.

Durance, an unnavigable river of SE. France, rises in the department of the Hautes-Alpes, and joins the Rhone 3 miles below Avignon, after a course of 235 miles. An aqueduct from it, 51 miles long, supplies Marseilles with water, and irrigates 25,000 acres, otherwise parched.

Durand, MADAME. See GRÉVILLE (HENRY).

Durandus, GULIELMUS (1237-96), born at Puimisson near Béziers, studied canon law at Bologna and Modena, and had held various offices under several popes, when in 1286 he became Bishop of Mende, still, however, remaining in Rome, where he died. His *Speculum Judiciale* (1271; first printed 1474) is his most famous work; of his *Rationale Divinorum Officiorum* (Mainz, 1459), book i. was translated by J. M. Neale and B. Webb as *The Symbolism of Churches* (1843), book iii. by T. H. Passmore as *The Sacred Vestments* (1899).

Durango (called also *Guadiana* and *Ciudad de Victoria*), a town of Mexico, on a dry plateau, 6700 feet above sea-level, 500 miles NW. of the city of Mexico. It is handsomely built, with a cathedral, a former Jesuit college, a theatre, and a mint, and has very rich deposits of iron ore and other minerals. Pop. 34,000.—The State of Durango (40,000 sq. m.; pop. 333,000), of which Durango is capital, consists of the mountain range of Sierra Madre in the west, and a dry plateau in the east. Several rivers drain to the Pacific, and the Nazas eastwards to an inland basin. Cattle and sheep are raised, and silver, iron, and other minerals got.

Durazzo (Serb *Draž*, Albanian *Durrësi*), a port of Albania on the Adriatic, 50 miles S. of Scutari. It is a poor, decayed place, with 5000 inhabitants, and a ruined citadel; but the harbour, though sanding up, is the most important of Middle Albania.—Durazzo is the ancient *Epidamnus*, founded about 625 B.C. by Corcyreans and Corinthians. It became a great and populous city, but was much harassed by the party strifes which ultimately led to the Peloponnesian

War. Under the Romans it was called *Dyr-rhacium* (whence its modern name), and became the principal landing-place for those sailing from Buundusium in Italy to Greece; and the great military road to the Hellespont began here. The town is memorable for the battles of Cæsar and Pompey in 48 B.C.; but it attained its highest consequence about the end of the 4th century A.D., when it became the capital of the Byzantine province of New Epirus. After being possessed successively by the Ostrogoths, the Bulgarians, the Normans, and the Venetians, and destroyed by an earthquake in 1273, it was conquered by the Turks in 1501. The Austrians took it in 1916, the Italians in 1918. It is the provisional capital.

Durban, or **PORT NATAL**, the seaport and largest town of Natal, is beautifully situated on the northern shore of a nearly land-locked tidal bay. Pop. (1866) 4991; (1891) 36,014; (1911) 69,187; (1921) 96,264, including some 48,500 natives, Indians, and other coloured persons. The climate, hot and rainy from November to March, is healthy for Europeans. Port Natal was named Durban after Sir Benjamin D'Urban, governor of the Cape, when Natal was declared British (1842).

In the heart of the town are public gardens, in which a new town-hall has been erected, with municipal offices, public library, museum, and art gallery. The law-courts are also new. Other conspicuous buildings include the post-office (old town-hall), market-house, and the railway terminus. Durban has a theatre, Botanic Gardens, a race-course, and several public parks. The Berea, a low range of hills overlooking the town, is a fashionable suburb with pretty villas and gardens. Municipal electric cars run along the main roads, and jinrickshas speed everywhere. An attractive marine beach has been laid out for holiday-makers. The town has efficient systems of lighting, drainage, and water-supply. Apart from shipping, Durban has few industries; it has dynamite-works, jam-factories, and a whaling-station. The Bluff, a bold, sheltering promontory at the southern entrance of the harbour, is fortified, and bears a lighthouse. North of the narrow entrance is the Point, with extensive quays, floating-dock, &c. Farther up are reclaimed lands with wharves, and a very large graving-dock (1920-24). The enclosed basin, over 7 square miles, is largely shoal water. For long Durban contended with a bar at the harbour-mouth; dredging and other devices at last brought success, and now vessels of deep draught can enter without difficulty. Coal, wool, hides, maize, sugar, and other South African products are exported; all Natal's imports, and much of the Transvaal's and Orange Free State's, enter *via* Durban. Railways run to the end of the Point and of the Bluff, north and south along the coast, and inland to Pietermaritzburg (70 miles), Johannesburg (483 miles), and Bloemfontein. See **NATAL**.

Durbar (Persian *darbâr*, 'court,' 'audience'), a state reception of the Emperor or Governor-general of India or one of the native princes. Specially memorable are those of 1877, when Queen Victoria was proclaimed Empress of India, and of 1911, when George V. received homage in person.

Düren (Roman *Marcodurum*), an ancient town of Rheinland, on the Roer, 18 miles E. of Aix-la-Chapelle. It has manufactures of cloth, iron and steel, paper, sugar, carpets, and beer. Pop. 34,000, of whom about 3000 are Protestants.

Dürer, **ALBRECHT**, the most celebrated artist of Germany, was born at Nürnberg, 21st May 1471. His father, a devout and excellent man, was a goldsmith, and he carefully trained his son, and instructed him in his own craft. But the youth showed greater inclination for painting, and in

very early years had already attained considerable artistic skill, as is proved by such drawings as the portrait of himself at the age of thirteen, now in the Albertina Collection, Vienna. He was accordingly apprenticed to Michael Wolgemut, the best painter in the town at the time, and the chief illustrator of the famous Nürnberg Chronicle. After serving his time under this master, Dürer started on his travels in 1490; and there is reason to believe that he found his way to Italy and visited Venice. On his return his father arranged a marriage for him with Agnes Frey, the daughter of a Nuremberg merchant. It has been constantly asserted that the union was an unhappy one, but Thausing, Dürer's most accurate biographer, has shown reason for believing that the letter of Pirckheimer, written two years after the painter's death, upon which this statement is founded, should be received with great caution. Dürer now established himself in his native town; and, largely aided by such assistants as Hans Leonhard Schaufelein, Hans von Kulmbach, and Hans Baldung, he executed many paintings, among which the triptych in the Gemälde Galerie, Dresden, and the fine Paumgartner altarpiece in the Pinakothek, Munich, may be named. In 1498 he published his first great series of designs on wood, the illustrations of the Apocalypse, which, it seems to be now generally admitted, were, like the rest of Dürer's work of the kind, cut upon the block by a professional engraver. The copper-plates of this period include 'The Prodigal Son,' assigned to 1500; the 'Shield of the Death's Head' (1503); the 'Shield with the Lion and Cock,' assigned to the same year, and in technique one of his most accomplished engravings; and the 'Adam and Eve' (1504). In 1504 he completed his 'Adoration of the Kings,' begun in tempera and finished in oils, now in the Tribune, Florence; and the elaborate copper-plate of 'St Eustachius' probably dates from the same time.

In 1505 Dürer visited Venice, with the view of arresting the piracy of his works by Marc Antonio, who had copied, line for line upon copper, certain of his woodcuts of the 'Life of the Virgin,' which had been executed previous to this date, though the completed work was not issued till 1511. Here he produced the 'Feast of the Rose-garlands,' now the property of Strahow monastery, Prague, of which he writes: 'I have also silenced the painters, who said I was a good engraver, but did not know how to manage colours. . . . There is not a better picture of the Virgin in the land.' On his return he painted his 'Adam and Eve' (1507), now in the Madrid Museum; and his 'Assumption of the Virgin,' a work executed with unusual care and elaboration, as is indicated by the painter's correspondence, and proved by the very numerous studies for its various parts which still exist. The central portion of this altar-piece, executed entirely by his own hand, was destroyed by fire in 1674. It was followed in 1511 by the All Saints' picture, styled 'The Adoration of the Trinity,' in the Vienna Gallery.

Dürer was much employed by the Emperor Maximilian I., of whom he executed several portraits, for whose prayer-book he designed a famous series of decorations, and in whose honour he drew the 'Triumphal Car' and the 'Triumphal Arch,' which were engraved on wood, the latter on ninety-two blocks, which when united form a surface 11 feet 3 inches by 10 feet wide—the largest known woodcut.

It was after the death of the emperor, and in order to recover sums due for his commissions, that the painter visited the Netherlands in 1520. His curious journal of the expedition has been preserved and published. At Antwerp he made the acquaintance of Erasmus, whose portrait he drew, and

afterwards engraved on copper, and he was present at the coronation of Charles V., who appointed him his court-painter; but among the swamps of Zealand he seems to have contracted a kind of low fever, and his health gradually failed, till he died at Nuremberg, 6th April 1528. During his later years the earnest and reverent-minded painter manifested great sympathy with the doctrines and progress of the Reformation; his journal in the Netherlands contains an impassioned outburst of grief, occasioned by the supposed death of Luther; and in 1526 he presented to the council of his native town a pair of companion panels, representing St John with St Peter, and St Paul with St Mark, inscribed with warning texts from Luther's translation of the Epistles.

Both upon technical and intellectual grounds Dürer ranks as the greatest of German artists; and his work is thoroughly national in character, fully expressive of all the homeliness and all the mysticism of the German nature. His paintings are distinguished by effective composition, careful manipulation, and forcible colouring; and that searching grasp of character and expression which renders his work in portraiture so valuable gives a sense of truth and reality to his subject-pictures also. His 'Four Apostles,' above referred to, and now at Munich, are interesting as exhibiting the final development of his pictorial style, being far broader in handling and larger in the disposition of the draperies than his earlier works. His masterly drawings and studies are very numerous, and are to be found in most public collections, those of the Albertina, in Vienna, and of the British Museum, London, being the richest. As an engraver on metal and a designer of woodcuts Dürer ranks even higher, and has certainly been more widely influential than as a painter. His work on copper and on wood is distinguished by the most unerring perception of the capabilities of his material, his metal-plates being executed with extreme finish and refinement, the burin being handled in a manner exceptionally free and painter-like; while his woodcuts are boldly drawn with a broad expressive line, such as could be easily followed by the engraver employed to cut the block. The most celebrated of his copper-plates, which number over 100, are those mentioned above; the 'Little Passion,' on copper (16 plates, 1508-13); 'St Jerome in his Study' (1514); and the 'Melancholia' (1514), and the 'Knight, Death, and the Devil' (1513)—two great imaginative designs, which are so filled with mysterious and poetic suggestiveness as to be susceptible of the most diverse interpretations. Dürer may also be regarded as the inventor of etching, as he produced several plates in which all the lines are bitten with acid, as well as others in which the process is used in preparation for work with the burin. His woodcuts are about 200 in number, including the 'Greater Passion,' 12 subjects; 'The Little Passion,' on wood, 37 subjects; 'The Apocalypse,' 16 subjects; and many single prints of religious, mythological, portrait, and heraldic designs. It has been asserted that Dürer executed several plastic works. The finest of these is the 'Birth of St John the Baptist,' a relief on soap-stone in the British Museum; but Thausing regards this and all similar works as spurious. Dürer was also author of various scientific writings, of which the *Instructions in Measurement* (1525), the *Treatise on Fortification* (1527), and the *Treatise on Human Proportion* (1528) are most important.

See *Lives* by W. B. Scott (1872), Mrs Heaton (1872), Thausing (trans. by Eaton, 1882), Barlow (1923); the French work of Ephrussi (1832); the German *Life* by A. von Eye (1882); Knackfuss, *Dürer und Holbein* (1895); and the monograph by Lionel Cust (1897). The standard editions of the prose writings are those by Jansen

(*Alb. Duereri Opera*, 1603) and by Lange and Fuhse (1893); an abridged English translation of them was published by Sir W. M. Conway in 1889. Reproductions of his metal engravings were published by Amand-Durand of Paris, and of his woodcuts of his 'Apocalypse' and 'Life of the Virgin,' by Van de Weijer of Utrecht. Thirty-three of the thirty-seven blocks of his 'Lesser Passion,' on wood, are preserved in the British Museum, and stereotype reproductions of these were issued in 1844 and succeeding years.

Duress, in English law, is the plea of a man who has obliged himself to pay or perform, or who has committed a misdemeanour, under compulsion by restraint of liberty, or threat of loss of life and limb. In such cases he may plead to be held free of the consequences.

D'Urfey, THOMAS, dramatist and song-writer, was born at Exeter in 1653. Of Huguenot descent he was boisterous in his Protestantism all his life. Shackerley Marmion was his remote kinsman; a nearer one was Honoré d'Urfé (1568-1625), author of the famous romance of *Astrée*. He early became a busy playwright, his comedies especially being popular. Among these were *The Fond Husband*, or *the Plotting Sisters* (1676); *Madame Fickle*, or *the Witty False One* (1677); and *Sir Burnaby Whig*, or *No Wit like a Woman's* (1681). In 1683 he brought out his *New Collection of Songs and Poems*, which was followed by a long series of songs in volumes and sheets, which were finally in 1719 collected into an edition in five volumes, as *Wit and Mirth*, or *Pills to Purge Melancholy*, supplemented by a sixth volume in 1720 (repr. 1872). Meanwhile D'Urfey had been busy with a long series of plays, for the morals of which he suffered like the rest from the heavy hand of Jeremy Collier. He never married; and though he was not particularly profligate, his fortunes had declined as his comedies ceased to please. Charles II. had done him the honour to lean upon his shoulder, but does not seem to have put anything in his pocket; the good Queen Anne had paid him fifty guineas for his singing to her at supper. Tom D'Urfey, as he was called by everybody, was very popular with his contemporaries, and seems to have been a cheerful, kindly, and fairly worthy fellow, convivial but not dissipated in his habits, loving and dutiful to his mother, if the evidence of pious verses may be believed. Benefits in his behalf were promoted by Addison and Steele, and the former thus pleaded in his behalf: 'He has made the world merry, and I hope they will make him easy, as long as he stays among us. This I will take upon me to say, they cannot do a kindness to a more diverting companion, or a more cheerful, honest, good-natured man.' D'Urfey died 26th February 1723. See Ebsworth's admirable article in volume xvi. (1888) of the *Dictionary of National Biography*.

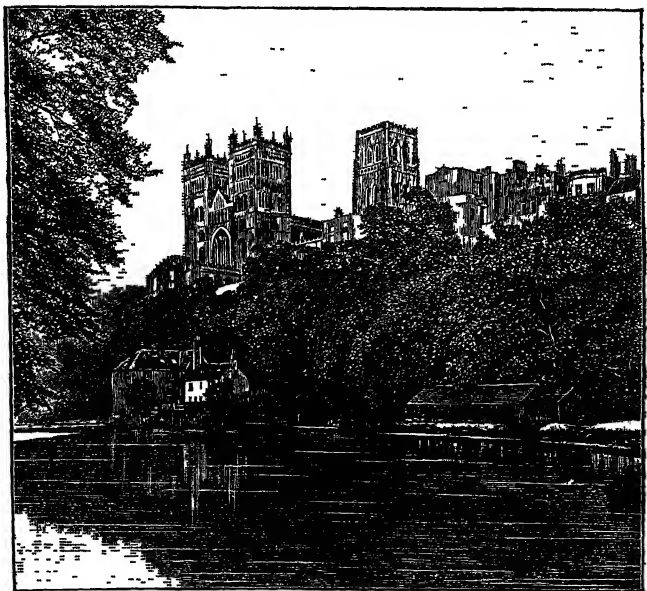

Durga, the wife of Siva (q.v.).

Durham, a maritime county in the north-east of England, between Tyne and Tees. It has 32 miles of coast, generally low, but with some cliffs; area of land and water, 1012 sq. m., two-thirds being arable. The surface is hilly, and slopes to the east. In the west, which is waste but rich in minerals, are branches of the Pennine chain, rising in Kilhope Law, 2196 feet; Collier Law, 1678; and Pontop Pike, 1018. The two chief branches inclose the valley of the Wear, and send forth several parallel ranges, declining toward the coast, and inclosing many fertile tracts and sheltered valleys. The chief rivers are the Wear, Tyne, and Tees, navigable respectively for 12, 15, and 10 miles. The rocks are new red sandstone, magnesian limestone, millstone grit, carboniferous limestone, rich in lead; and coal-measures, forming the valuable Durham coalfield, 25 by 10 miles, with many

faults, and with about forty beds of coal, 3 to 10 feet thick. Basalt and greenstone trap dykes intersect the west part of Durham. The mineral products are coal, limestone, black marble, freestone, ironstone, firestone, slate, millstone, grindstone, iron pyrites, fluor-spar, zinc, barytes, and lead. The principal lead-mines are in Teesdale and Weardale. The production of lead, once important, has dwindled away; and the zinc mines have been given up. Large furnaces for the production of iron are in operation in various parts of the county. Durham has the largest coal production of any county in England, the number of persons employed above or below ground at the mines being over 150,000. The chief shipping ports are Stockton-on-Tees, South Shields, Sunderland, and Hartlepool. In the eastern districts it is intersected in all directions by railways. The soil is a clayey or dry loam. The chief crops are oats, wheat, barley, turnips, potatoes, and other green crops. The Teeswater or Holderness breed of cattle is famed for fattening, quantity of milk, and early maturity. The Durham horses are famed for draught, and the saddle. Many sheep are pastured on the hills. There are manufactures of iron and steel, coke, alkalies and chemicals, and salt, and much shipbuilding at Jarrow, Sunderland, South Shields, Hartlepool, and Stockton. Coal is the chief export. Durham is one of the three counties palatine (see PALATINE) of England, the other two being Lancaster and Chester. It was the only county palatine in the hands of a subject, and belonged to the Bishop of Durham. By 6 and 7 Will. IV. c. 19, the palatine jurisdiction was separated from the bishopric, and vested in the crown. Till 1844 three wards adjoining Berwick formed a detached part of Durham; they were then incorporated with Northumberland. The county is divided into four wards. It is entirely in the diocese of Durham. Pop. (1801) 149,384; (1841) 307,963; (1881) 867,576; (1921) 1,478,506. The chief towns are Durham, the county town, Sunderland, Darlington, Gateshead, South Shields, Stockton, and Hartlepool. The county includes eleven parliamentary divisions, each returning one member; and the following parliamentary boroughs: Sunderland, returning two members, and Darlington, Gateshead, Hartlepool, South Shields, and Stockton, each returning one. Durham has some ancient barrows, and has afforded many Roman antiquities, as altars, urns, and coins. There are extensive remains of Roman stations at Lanchester, Binchester, and Ebchester. Durham formed part of the kingdom of Northumbria (547-827). Later it suffered severely from the incursions of the Scots. See county histories by R. Surtees (1816-40) and W. Fordyce (1855-57); Lapsley, *County Palatine* (1900); 'Victoria History' (1905 *et seq.*); Mawer, *Place-names of Northumberland and Durham* (1921); Vikar, *Durham Dialect* (1922).

Durham, a municipal (till 1918 parliamentary) borough, and ancient episcopal city, near the middle of Durham county, 12 miles S. of Newcastle, is built around a steep rocky hill 86 feet high, nearly encircled by the Wear. On the top of the hill are the cathedral and castle. Ancient walls partly enclose the hill, from which are fine views of the fertile wooded country around, and of the suburbs across

the river. Its manufactures (mustard, carpets, and iron) have decayed. In the vicinity are coal-mines and coke-ovens. Pop. of municipal borough (1841) 14,151; (1921) 17,329. Once it sent two members to parliament, but from 1885 to 1918 only one. Durham arose about the year 995, when Bishop Aldune brought hither St Cuthbert's bones from Ripon, and built a church to enshrine them. On the site of this church, Bishop William de Carlepho, about 1093, began the present cathedral, one of the noblest specimens of Norman architecture in the kingdom, alike from situation and from structure, that massive pile—'half church of God, half castle 'gainst the Scot.' To the main structure various additions continued to be made up till 1500; and the whole has on various occasions undergone extensive renovation. Its extreme length is 510 feet; length of the transept, 175 feet; height of the central tower, 214 feet; and height of the two western towers, 138 feet. The cathedral contains many old monuments, and the tombs of St Cuthbert (q.v.) and of Bede. The castle, once the residence of the bishops of Durham, but now occupied by the university, was founded about 1072, by the Conqueror, in the Romanesque style, but it has received many alterations and additions. The dormitory of the monastery of Durham, now the new library of the cathedral, is one of the finest in England. The see extends over the county of Durham (Northumberland having been detached in 1882 to form the diocese of Newcastle); among the bishops of Durham have been Bek, Aungerville, Wolsey, Cosin, Butler, and Lightfoot. Two of the bridges over the Wear dated originally from the 12th century. Durham possesses seven parish churches, a town-hall, a miners' hall, large prison, grammar-school, diocesan training-colleges, and a school of art.

Durham Cathedral.

A college was founded in Oxford in 1290 by the prior and convent of Durham. It was abolished, however, at the dissolution of monastic houses in the reign of Henry VIII, and its endowments given to the dean and chapter of Durham. Under the Commonwealth, Cromwell instituted a college here, and endowed it with the sequestered revenues of the dean and chapter, to whom, however,

these revenues again reverted at the Restoration, when Cromwell's college was suppressed. The present university of Durham was opened for students in 1833, under the provisions of an act of parliament, obtained by the dean and chapter during the previous year. A royal charter in 1837 empowered the university to bestow degrees. Licentiates in theology must be members of the Church of England; but otherwise subscription is not required from any member of the university. Among its colleges are University College, Hatfield's College, and the College of Medicine at Durham, and Armstrong College at Newcastle-on-Tyne.

Durham, JAMES, a Covenanting minister, was born at Easter Powrie, in Forfar, in 1622, studied at St Andrews, fought as captain in the Civil War, and became a preacher in 1647. He was chaplain to Charles II. in 1650-51, and minister in Glasgow till his death, 25th June 1658. He left numerous sermons and several expository works, but is best known for his *Clavis Canticae, or an Exposition of the Song of Solomon* (1668).

Durham, JOHN GEORGE LAMBERTON, EARL OF, an English statesman, was born, the descendant of an ancient Durham family, in London on the 13th April 1792. Of decided liberal sympathies, he was in 1813 returned for the county of Durham, and though he did not speak on many questions, he took an active part in furthering all projects of a reforming tendency, even bringing forward in 1821 a scheme for parliamentary reform much more advanced than that of 1832. In 1828 he was raised to the peerage, with the title of Baron Durham of the city of Durham. Under the administration of Lord Grey (1830) he held the office of Lord Privy Seal, and was one of the four persons who drew up the Reform Bill, and supported it in the House of Lords. He was not in cordial relations with his colleagues, and resigning his office on the plea of ill-health in 1833, was made an earl. For a time he was ambassador at St Petersburg. In 1838 he was appointed Governor-general of Canada, where, owing to the revolt of the French in Lower Canada, the constitution had been suspended. Lord Durham's measures were statesman-like but dictatorial; and the House of Lords voted disapproval of some of his acts. Thereupon he took the extraordinary step of returning to England without either being recalled or obtaining the royal consent. His famous report on Canada (falsely attributed to Charles Buller; and edited in 1912 by Sir C. P. Lucas) anticipated many of the best features in the present Canadian constitution. He died at Cowes, 28th July 1840. See his *Life and Letters*, by Stuart J. Reid (1906).

Durham, SIMEON or SYMEON OF, historian, was a monk of Durham. His *Historia Ecclesie Dunelmensis* seems to have been written between 1104 and 1108; his *Historia Regum Anglorum et Dacorum* comes down to 1129. Other works have been attributed to him. Simeon, who became precentor of Durham, seems to have been dead in 1138. See his *Opera Omnia*, edited by Thomas Arnold (Rolls Series, 1882-85).

Durian, or **DURION** (*Durio zibethinus*), an Indian and Malayan fruit-tree of Malvaceous affinities, usually reckoned in the order Bombacaceae. It is a lofty tree, with leaves resembling those of the cherry, and large bunches of pale-yellow flowers. The fruit is of the size of a man's head, roundish oblong, with a hard thick rind, covered with soft spines. The pulp is of a creamy consistence and delicious taste, but has a putrid smell which is at first very repulsive. Persons accustomed to it, however, universally regard the durian as one of the very finest fruits of the East. It contains ten or twelve seeds, as large as

pigeons' eggs, which, when roasted, are not inferior to chestnuts. One tree yields about 200 durians in a year.

Dürkheim, a small town of Rhenish Bavaria, 6 miles SW. of Mannheim, at the base of the Hardt Mountains, with mineral wells and salt-works.

Durlach, an old town of Baden, on the Pfalz, at the base of the Thurnberg, 4 miles E. of Carlsruhe, manufactures linen, iron, sewing-machines, &c., and has fruit and grain markets; pop. 15,000.

Durostor, a Rumanian department in the Dobrudja.

Durra (*Sorghum*), a genus of grasses, which is also called Durra Millet and Indian Millet, or Sorgho Grass. The genus is closely allied to sugar-cane (*Saccharum*) and Beard-grass (*Andropogon*). The species are generally annual, tall, broad-leaved grasses, having strong culms filled with a juicy and saccharine pith, and large panicles. Several of them are cultivated as corn-plants, chiefly in Asia and Africa, particularly the common durra (*S. vulgare*—*Holcus Sorghum* of the older botanists), also called Joar and Jowaree in India. It grows 4 to 8 feet high, with thickly crowded panicles. It is a coarse, strong grass; its grain is round, a little larger than mustard seed. It is extensively cultivated in Asia Minor, India, the Sudan, and South Africa, and may perhaps be described as the principal corn-plant of Africa. It is also cultivated to a considerable extent in the south of Europe, sparingly in Italian Switzerland. In Germany the summer is not long and warm enough. The climate of Britain is still less suitable. Durra yields a very abundant produce, in this respect even rivaling maize, but the meal does not make good bread; it is excellent, however, prepared in other ways. The culms and leaves are excellent food for horses and cattle, as is the grain, which is useful also for brewing and distilling purposes. In Armenia it is grown as fodder, and yields as many as seven or eight crops.—The seeds of the Shaloo or Sugar-grass (*S. saccharatum*) are more pleasant to the taste than those of the common durra. It is cultivated in the warm parts of Asia and in Africa, and has a diffuse and very spreading panicle. The sweet pith of the culm is eaten, and is also of value as a source of sugar, for which it is successfully cultivated in the United States (see SUGAR).—**KAFIR CORN** (*S. caffrorum*) is largely cultivated in South Africa, both by Kafirs and by the colonists; by the latter chiefly for feeding horses.—*S. halepense* is a troublesome weed in North Italy, like couch-grass. Its sweet rhizomes furnish a local substitute for sarsaparilla.

Dürrenstein, a village of Lower Austria, is situated in a highly picturesque locality, on the left bank of the Danube, 45 miles WNW. of Vienna. In its ruined castle, Richard Cœur-de-Lion was confined by Leopold of Austria for three months.

Dursley, a town of Gloucestershire, amid picturesque scenery, near the Cotswold hills, 15 miles SW. of Gloucester by rail. Near it are quarries of Bath-stone.

Duruy, VICTOR, historian and educationist, was born in Paris, 11th September 1811. Destined for a designer in the Gobelins tapestry-works, he showed singular aptitude for learned studies, and, entering the École Normale in his nineteenth year, in 1833 became professor of History in the Collège Henri IV. From 1863 to 1869, he was Minister of Public Instruction, and as such carried out some important reforms, though his scheme for free and compulsory education was defeated by the clericals.

His numerous and important works, published between 1838 and 1879, include historical geographies of the Roman empire, of the middle ages, and of France, histories of France and Greece, and his *magnum opus*, the *Histoire des Romains* (trans. 6 vols. 1853-86). He was Grand Officer of the Legion of Honour (1867), and member of the Academy (1885), and died 25th November 1894. See *Life by Lavisse* (1895).

Dushan. See SERBIA.

Dussek (pronounced *Dushek*), JAN LADISLAW, composer and pianist, born 9th February 1761, at Czaslau in Bohemia, and became organist at Mechlin and Bergen-op-Zoom. At Amsterdam he met with much success, both as a teacher and performer, and here he produced his earliest works for the pianoforte; he afterwards resided at the Hague, and in Hamburg, Lithuania, Paris, Milan, and London (1788-1800), where he was very popular. In 1803-6 he lived as instructor and boon companion with Prince Louis Ferdinand of Prussia, whose death called forth the beautiful and pathetic 'Élégie Harmonique' (op. 61); in 1807 he entered the service of Prince Talleyrand, and thenceforward devoted most of his time to composition. He died at St Germain-en-Laye, 20th March 1812. To his contemporaries Dussek was the greatest of pianoforte specialists; there was a fascination in his style that raised him above even Clementi and Cramer. Of the seventy-seven numbered opus works, besides many without opus numbers, which he left behind, all, with few exceptions, were shortly forgotten.

Düsseldorf, the chief town of the populous district of Düsseldorf, in Rheinland, is situated on the right bank of the Rhine, at the influx of the Dussel, 24 miles NNW. of Cologne. It was formerly fortified, but its ramparts were converted into promenades in 1802, after the treaty of Lunéville. The streets, many of which are planted with rows of trees, are regular and spacious, while the eleven squares and the extensive garden-grounds in and near the town, are tastefully laid out and embellished with fountains and statues. Düsseldorf has recently considerably developed its trade and industries, but its chief importance is still as a centre of art. In the marketplace rises a colossal equestrian statue of the Elector Johann Wilhelm, who founded a famous picture-gallery here in 1690, most of which, however, was removed to Munich in 1805. The Düsseldorf Academy was founded in 1767, reorganised in 1822, and attained great eminence during 1822-59, under the management of Cornelius and Schadow. Its reputation has again begun to revive. The present building, an imposing Renaissance edifice, with a façade 520 feet in length, was finished in 1879. The Art Hall (1881-1902) contains a gallery of modern paintings. Among the other principal buildings are the old electoral palace (1710-1846; burned 1872); the present palace, the residence of the governor of the province; the government house, the observatory, town-hall (1567), theatre, gymnasium, and public library (90,000 vols.). Of about forty churches the most remarkable are those of St Andrew, formerly the church of the Jesuits, a handsome and highly ornate structure completed in 1629, and St Lambert, dating from the 14th century. The Hofgarten is one of the finest public gardens in Germany. Adjoining it are the house and garden of the philosopher Jacobi, now the property of the famous 'Malkasten' club of artists. The iron and cotton industries are very important, employing thousands of hands. Düsseldorf has also manufactures of pianofortes, paper, soap, beer, chemicals, tobacco, chocolate, glass, &c., besides mills of all kinds, and photographic, lithographic, printing, and

other institutions. Its rapidly growing commercial and industrial importance is fostered by its situation on the Rhine and at the junction of several railways. Düsseldorf is also an important educational centre. Pop. (1875) 80,750; (1885) 115,190; (1900) 213,767; (1910) 358,728; (1919) 407,338. Made a town by the Duke of Berg in 1288, it became the capital of the duchy in 1385; and in 1609 passed to the Palatinate. In 1806 it became the capital of the duchy of Berg, which was revived for a brief period by Napoleon, and in 1815 was united to Prussia. It was made a free port in 1829. The brothers Jacobi, Heine, Varnhagen von Ense, and the painters Cornelius and Peter von Hess, were born at Düsseldorf.

Dust is present in the atmosphere from various causes. The existence of dust in the air of a room or in a liquid is proved by the fact that we can trace the course of a beam of light through the air or the liquid by means of its partial reflection from suspended motes. The dust in the atmosphere is carried up in part from the earth's surface by currents of air, and in part by evaporation. A great part of it is due to volcanic action, and part also, the so-called 'cosmic dust,' has a meteoric origin (see METEORS). The blue colour of the sky is due to the reflection of light from particles of dust, possibly even from particles of air. Aitken showed that no condensation of moisture in the air (as in rain, mist, fog; see FOG) could occur without nuclei such as dust particles. He also devised an apparatus for counting the number of dust particles in a given sample of air or gas.

Dust-brand. See SMUT.

Dusty-foot. See PIPEPOWDER COURT.

Dutch is an English form corresponding to the German *Deutsch* (old *Drutisk*, 'belonging to the people'), which by them is used specifically for German, and in a wider sense is applied to both High German (*Hochdeutsch*) and Low German (*Niederdeutsch*), of which Plattdeutsch (q.v.) is a variety, or still more widely for Germanic or Teutonic (see TEUTONS). *Teutones* is from the same root. Formerly *Dutch* and *Dutchland* were used in English for 'German' and 'Germany,' what is now called 'Dutch' being then 'Low Dutch'; but 'Dutch' has been long restricted in its reference to Holland and the things thereto pertaining. The people of Holland (who call themselves *Nederlandsch*) use their forms *Duitsch*, *Nederduitsch*, as the Germans do *Deutsch*, *Niederdeutsch*. For Dutch Language and Literature, see HOLLAND.

Dutch Liquid is an oily substance obtained by mixing chlorine and olefiant gases, which combine together and yield Dutch liquid, with the formula $C_2H_4Cl_2$. It has a specific gravity of 1.271 (water = 1.000), boils at 185° (85° C), is not miscible with water, but readily dissolves in ether and alcohol. It produces Anæsthesia (q.v.), just as Chloroform (q.v.) does; but the great difficulty of preparing Dutch liquid in commercial quantities retards its employment as an anæsthetic.

Dutch Metal, sometimes called *Dutch gold* or *Dutch leaf*, is an alloy of copper and zinc. In other words, it is a kind of brass containing a large percentage of copper. It is made in the same manner as gold-leaf, and is said not to exceed $\frac{1}{1000}$ inch in thickness. Dutch leaf dissolves in strong nitric acid; true gold-leaf does not. The former is also easily tarnished. Ordinary Dutch metal is yellow, but a white kind is made, and both are used for coffin furniture.

Dutch Rushes. See HORSETAILS.

Dutens, LOUIS, a French writer, was born at Tours, 15th January 1730. A Protestant, he came to England about 1750, went with the English

ambassador to the court of Turin as his secretary, and afterwards remained as *chargé-d'affaires*. He held a pension, in 1766 was presented to the rich living of Elsdon, in Northumberland, and was likewise made Historiographer Royal of Great Britain. He died 23d May 1812. He undertook the first comprehensive edition of Leibnitz's works (6 vols. Geneva, 1768), and wrote books on the history of discoveries, English politics, theology, numismatics, &c., and poems. See his *Mémoires* (1806; trans.).—His nephew, JOSEPH MICHEL DUTENS (1765-1848), wrote on political economy.

Duty. See CUSTOMS, EXCISE, TAX; ETHICS.

Duval, CLAUDE, highwayman, was born at Domfront, Normandy, in 1643, and came to England at the Restoration, in the train of the Duke of Richmond. Taking soon to the road, he robbed many gentlemen of their purses, and ladies of their hearts, till, having been captured while drunk, he was hanged at Tyburn on 21st January 1670, and was buried in Covent Garden church.

Dvinsk. See DÜNABURG.

Dvořák (pronounced *Dvorzhak*), ANTONIN, the Bohemian composer, was born at Mühlausen, near Kralup in the Prague district, on the 8th September 1841. He had more difficulties to overcome in his pursuit of education than the majority even of music's least favoured sons. His father was a butcher, and could ill afford to allow his son to indulge the tastes which a few lessons from a local musician had deeply implanted in the boy. At a great sacrifice, however, he sent his son in 1857 to Prague, which was thereafter the headquarters of his uneventful life. In 1873, after years of the dullest hack-work in café orchestras and as a church organist, he composed a hymn for chorus and organ which attracted attention. Attention begat ever-increasing interest, until two years afterwards the Austrian government conferred on him a *staats-stipendium* or annual allowance from the treasury. Brahms introduced his compositions to the musical public in Vienna; but the work which won for him the ear of all Europe was his *Stabat Mater*, which speedily became a favourite, especially in England, where it was first performed by the London Musical Society in 1883. This work rises above the strong influences of national feeling so generally found in Dvořák's writings into a more cosmopolitan atmosphere, and challenges comparison with the most universally accepted settings of the Latin hymn. Other compositions are songs, &c., very spontaneous and delicate (*Seven Gypsy Songs*, op. 55), and piano-forte compositions (*Dumka* or *Elegy*, *Furiante* or Bohemian Dances, *Slav Dances*), in all of which he has made very large use of national melodies and dance rhythms; also chamber music of great beauty (*E flat Quartette*, op. 51). His most ambitious work is orchestral (*Symphony in D*, &c.) and choral. *The Spectre's Bride* (cantata written for the Birmingham Festival of 1885) is comparatively short. The *Stabat Mater* commands the admiration of all earnest musicians. *St Ludmila* (an oratorio written for the Leeds Festival, 1886) is long and dreary. His opera, *Der Bauer*, was unlucky; *Der Jacobin* (1889) was better received; *Der Teufel und die wilde Kathe* was the work of 1899. In 1892-95 he was director of the New York Conservatory of Music; after 1895 he settled in Prague. In the symphonies, *From the New World* and *In Nature*, he utilised negro melodies. He died 1st May 1904.

Dvořák deliberately turned to folk-song and national dance as a fountain of originality; and musical Europe, so long accustomed to Teutonic inspiration, gladly heard the new rhythms and strange

harmonic effects of the Slav races. The characteristics of Dvořák's compositions are, first, the strong Czech element which pervades them, and displays itself in characteristic rhythmical effects and relations of tonalities, peculiar and indistinct to Western ears; secondly, the economical and often extremely clever use of small thematic material; and thirdly, notwithstanding this economy, his lavish use of rich and fresh melody, as if it were as easy to write a new melody as to repeat an old.

Dwale, an old name for deadly nightshade. See BELLADONNA.

Dwarf (A.S. *dweorg*, *dwergr*, or *dweorh*; cf. Icel. *dvergr*, Ger. *zwerg*) is a term applied to any organised being, but especially to the human species, whose height is much less than the average height of their race. The word is often restricted to those cases where there has been a uniform and general arrest of growth, except perhaps in the nervous system, which is often fully developed in dwarfs. See DEFORMITIES.

The ancients believed not only in dwarfs, but in nations of them. Aristotle declared that the report of trustworthy witnesses testified to the existence of a minute race of men, with minute horses, living in caves which are washed by the waters of the Nile; and Pliny gives details as to their habits and geographical position. There were also, according to later writers, pygmies (Gr. *πυγμαι*, 'the fist') in Thule and beyond the Ganges. Greek fancy delighted to paint their Lilliputian dimensions: they cut down every corn-ear with axes; when Hercules came into their country, they climbed by help of ladders up to his goblet, to drink from it.

Of dwarf races of man, the most notable are the Bushmen (q.v.), 4 feet 7 inches high; the Akkas (q.v.) in Central Africa, about 4 feet 10 inches high, with whom Emin's men identified the hordes of forest dwarfs ('a venomous, cowardly, and thievish race, and very expert with their arrows') by whom Stanley's march in 1888 was so harassed; the Obongos on the Gabun, and the still smaller Batwas, 4 feet 3 inches (see AFRICA); a tribe called M'Kabba, near Lake Ngami, reported as only 4 feet 1 inch; the Tapiro pygmies in Dutch New Guinea, 4 feet 9 inches; also the Andaman Islanders (under 5 feet), the Aetas in the Philippines, the Malayan Samangs, the Javan Kalangs. The Lapps, Ainus, and Veddas are somewhat taller.

Dwarfs play a large part in the mythology of the ancient Germanic nations. They had their own kings, and dwelt in caves and rocky cavities in the interior of the earth, wherein are priceless treasures, metal, and wondrous works of art. It is they who forge for the gods their armour, who gave Odin his spear, and Thor his hammer Mjölnir. Some of the attributes of the dwarfs are supposed to have been derived from an actual race of small stature—the Lapps, who occupied part of the Scandinavian peninsula before the immigration of the Gothic Scandinavian peoples (see SCANDINAVIAN MYTHOLOGY, and Grimm's *Deutsche Mythologie*). British tradition tells of a 'Tom Thumb' at King Arthur's court; and Gulliver's Lilliputians are amongst the most familiarly known of all dwarfs.

Dwarfs were not unfrequently retained as court favourites or toys down until the 18th century; more recently they have been popular as curiosities exhibited in shows. Of ancient dwarfs, Philetas of Cos, tutor of Ptolemy Philadelphus, was said to have worn weights in his pockets to keep him from being blown away, and a niece of Augustus had two dwarfs said to have been only 2 feet 4 inches. Gibson and his wife, dwarfs of Queen Henrietta Maria, had a united height of 7 feet 2 inches. Jeffery Hudson (called Sir Geoffrey, and known to

as from *Peveril of the Peak*) was 3 feet 9 inches. 'Bébé,' dwarf of King Stanislaus of Poland, was only 23 inches in height, and died aged ninety in Paris in 1858. Count Borowski, a Pole of birth and accomplishments, was at thirty years of age but 3 feet 3 inches in height; he died in England in 1837. Charles Sherwood Stratton (1838-83), the American dwarf known as General Tom Thumb, was exhibited in England by Barnum in 1844. In 1863, when 31 inches in height, he married Lavinia Warren, aged twenty-one, and 32 inches in height. They, with their child and a dwarf called Commodore Nutt, visited England in 1864. The so-called 'Aztecs,' and Flynn, a New Yorker called General Mite, and only 21 inches high, are among dwarfs who have been exhibited in England. Many jockeys restrict their stature and are practically dwarfs. Unlike giants, who are usually feeble in body and mind, ill-proportioned and short-lived, many dwarfs are strong, well-proportioned, active, and intelligent. Some have spoken four or more languages. See E. J. Wood's *Giants and Dwarfs* (1868), and Tyson's *Pygmies of the Ancients* (1699; reprinted 1896); and for causes, &c., *Dwarfism* (1912), by Rischbieth and Amy Barrington.

Dwarfed Trees, growing in flower-pots, are a characteristic ornament in Chinese and Japanese houses and gardens, and the production of them is an art which has been carried to great perfection. It depends on the prevention of an abundant flow of sap, so that whilst the tree is kept living and healthful, vegetation does not go on with its natural activity. The trees are planted in shallow and narrow flower-pots; care is taken that their roots never pass into the ground beneath; they are very sparingly supplied with water; their strongest and leading shoots are pinched off, and their branches are bent and twisted in various ways. A very extraordinary dwarfing is the result of these and other such processes; and the dwarfed trees not unfrequently abound in flowers and fruit.

Dwarka, a maritime town of Guzerat, India, on the west side of the peninsula of Kathiawar, in the dominion of Baroda, 235 miles SW. of Ahmedabad. On an eminence overhanging the seashore stands a great temple of Krishna, visited annually by 10,000 pilgrims.

Dwight, DR TIMOTHY, a well-known American theologian, was born at Northampton, in Massachusetts, May 14, 1752, grandson of Jonathan Edwards; he studied at Yale College, and was licensed to preach in 1777. During the War of Independence, he was for some time a chaplain in the Continental army. In 1783 he became minister of Greenfield Hill, in Connecticut, where he also conducted an academy for twelve years with distinguished success. The College of New Jersey conferred on him the degree of S.T.D. in 1787, and Harvard that of LL.D. in 1810; in 1795 he was elected president of Yale College and professor of Divinity. He died January 11, 1817. His principal work is his *Theology Explained and Defended in a series of 173 Sermons* (5 vols. Middletown, Conn. 1818), which has gone through a great number of editions both in America and in England. Among his other writings may be mentioned *The Conquest of Canaan* (1785), an ambitious epic poem, and *Travels in New England and New York* (4 vols. 1821), reckoned by Southey the most important of his works.—A grandson, a second **TIMOTHY DWIGHT**, born in 1828, was in 1886-99 president of Yale University, and was a member of the American committee for the revision of the English version of the Bible.

Dwina, the name of two important rivers of Russia.—(1) The Northern Dwina has its origin in the confluence of the Suchona and the Jug, two

streams rising in the south of the government of Vologda, and uniting in 60° 46' N. lat., 46° 20' E. long. The Dwina flows generally north-west through a flat country, to the Gulf of Archangel, which it enters by three principal mouths, of which only the easternmost is useful for navigation. The length of the Dwina is about 450 miles (with the Suchona, 760); its basin embraces over 140,000 sq. m. Its chief tributaries are, on the left, the Vaga and Emza, and on the right the Pinega and the Vytchegda, the last having a course of some 625 miles, 500 being navigable. The volume of water poured down by this main tributary increases the breadth of the Dwina from about one-third to nearly two-thirds of a mile; near Archangel it widens to over four miles. The river is free from ice from May to October, and is a valuable channel of inland trade. Its waters also are rich in fish.—(2) The Western Dwina (Ger. *Duna*) rises in the government of Tver, not far from the sources of the Volga and the Dnieper, and flows at first WSW. in a course almost parallel to the latter. Below Vitebsk it turns WNW., crosses Lettland, and enters the Gulf of Riga. About 580 miles long, it is navigable from the confluence of the Mezha downwards, although the numerous shallows and rapids greatly impede traffic. Its basin is estimated at 32,850 sq. m.; its average depth of 26 feet at Riga is increased to about 40, and its breadth of 1400-2400 feet is extended in some places to a mile during the heavy spring floods which overflow wide tracts of the low-lying lands on either bank. The Western Dwina is connected with the Dnieper by the Beresina Canal, and by other canal systems with the Caspian, the Neva and Gulf of Finland, &c.

Dwinsk. See DÜNABURG.

Dyaks, or **DAYAKS**, is the Malay name for the race who constitute the bulk of the aboriginal population of Borneo, divided into innumerable tribes, differing pretty widely in language, customs, and degrees of savageness. Physically they closely resemble the Malays, to whom they are doubtless akin, but are somewhat taller; they are intelligent, hospitable, and unsuspicious, and greatly excel the Malays in truthfulness and honesty. Many of the dialects spoken by them are little known; but they seem all to fall into some five great geographical groups. The coast tribes have adopted many Malay words, and some have completely adopted the Malay speech. Even the most uncivilised tribes have many ingenious arts and industries, weave cloth, make excellent steel weapons, and erect most serviceable suspension-bridges with bamboo poles and withes. Their chief weapon is the Blowpipe (q.v.), not the bow. The barbarous custom of systematic 'head-hunting' is dying out, though the heads of enemies are still cherished trophies of the warrior. The Sea-Dyaks were long famous as untamable pirates. See BORNEO.

Dyce, ALEXANDER, an assiduous English critic, was born at Edinburgh, 30th June 1798. He spent part of his boyhood at Aberdeen, and had his education at the Edinburgh High School, and Exeter College, Oxford, where he graduated B.A. in 1819. He took orders, but soon abandoned the clerical calling to settle in London as a busy man of letters. His name will never be forgotten for the rare combination of learning, patience, and sagacity in his great editions of the dramatists, Peele (1828-39), Webster (1830; new ed. 1857), Greene (1831; in one vol. with Peele, 1858), Shirley (a completion of Gifford's ed. 1833), Middleton (1840), Beaumont and Fletcher (1843-46), Marlowe (1850; new ed. 1861), and Ford (a revised ed. of Gifford's, 1869). His edition of Shakespeare (9 vols. 1857; new ed. 1864-67) is not yet superseded. Besides these he edited between 1831 and 1835 the poems of Shake-

spears, Pope, Akenside, and Beattie, for Pickering's Aldine Edition of the Poets. Other works were his edition of Richard Bentley's works (1836-38), of Skelton's works (1843), and his *Recollections of the Table-talk of Samuel Rogers* (1856). He edited for the Camden, Percy, and Shakespeare societies, and was one of the severest assailants of Payne Collier's Shakespeare vagaries, an act of duty which ended an old friendship. Dyce died 15th May 1869, bequeathing his fine library to South Kensington Museum.

Dyce, WILLIAM, R.A., painter, was born at Aberdeen in 1806, and at 16 graduated M.A. of Marischal College. After acquiring the rudiments of his art-education he went in 1825 to Rome, where he developed a tendency towards early Italian or pre-Raphaelite art. In 1830 he settled in Edinburgh, where, besides painting portraits, he contributed largely to the exhibitions. In 1837 he was appointed master of the 'Trustees' Academy'; and eighteen months later he left for London, where he held various appointments in connection with the New School of Design at Somerset House. In 1844 he was appointed professor of Fine Arts in King's College, London. He was one of the artists selected to decorate the Palace of Westminster and the House of Lords, and at Osborne House several works in fresco were executed by him. Dyce was elected an A.R.A. in 1844, an R.A. in 1848. The following are some of the works he exhibited in the Royal Academy: 'King Joash shooting the Arrow of Deliverance,' a 'Madonna and Child' (1846), a 'Meeting of Jacob and Rachel' (1850), 'Christabel' (1855), 'The Good Shepherd' (1856), 'Neptune assigning to Britannia the Empire of the Sea'—a study for a fresco at Osborne (1857), 'St John leading Home his Adopted Mother,' 'The Man of Sorrows' (1860), and 'George Herbert at Bemerton' (1861). Dyce was a man of singularly wide culture, and an accomplished musician. In 1842-43 he published a sumptuous edition of the Prayer-book, with a dissertation on *Plains-chant*, and its use in the English service. He died at Streatham, 14th February 1864.

Dyck, SIR ANTHONY VAN. See VAN DYCK.

Dyca, a village of southern Alaska, on the Chilkoot Inlet, once important as the starting-point of the Chilkoot Pass route to Klondike and the Upper Yukon, superseded by the railway from Skagway to Whitehorse.

Dyeing is the art of imparting colours to textile and other materials, such as cotton, silk, wool, and leather. It has been practised among Eastern nations from time immemorial; and in the Old Testament we read of the purple-dyed vestments of the high-priests, of linen cloths dyed blue, purple, and scarlet, and of rams' skins dyed red. The famous Tyrian purple, obtained from one or two species of shell-fish, is believed to have been discovered by an inhabitant of Tyre fifteen hundred years B.C.; afterwards this purple became the badge of royalty, and cloth dyed with it commanded a princely price. Purple of various shades was dyed not only at Tyre, but at Tarsus, Alexandria, and other places on the shores of the Mediterranean, though other colours were, of course, employed. The Egyptians, Greeks, and Romans practised the art of dyeing. There is an ancient Roman dyer's workshop with its apparatus to be seen among the ruins of Pompeii. Gradually the art became more and more widespread as civilisation advanced. In earlier times dyeing was much more extensively followed as a domestic art than it is at present, but in some outlying parts of Europe, and even in the Highlands of Scotland, the colours imparted to home-made fabrics are still to some extent obtained from native vegetable dyes. The dyeing of indigo,

madder, and several other vegetable and animal dyestuffs was practised thousands of years ago. In the Middle Ages the Italians were famous for their dyeing, and, as they were at that time the great maritime nation, they introduced large numbers of new dyes from the East. The discovery of America caused another incursion of new dyes, such as logwood, cochineal, &c. As these imported dyes competed with the native products, very stringent laws were passed to prevent their use. It is only within the last hundred years that the art of dyeing has been put on a scientific basis. Before that time it was almost entirely empirical, and all sorts of substances were added to the dye-baths with the supposed effect of improving the dyeing. Some of the old receipts contain as many as thirty ingredients. The starting-point for the modern practice of dyeing is the year 1856, in which the first artificial coal-tar dyestuff was prepared by Sir W. H. Perkin. This dye, known as Mauve, was for a large number of years used for printing the lilac-coloured one penny stamps. Since that date the number of coal-tar dyes has increased enormously, and they can now be counted by thousands, and hundreds of new ones are added every year. One result of this is that the natural dyes have been very largely replaced by the artificial products, as the latter usually give much brighter shades, and are more easily applied.

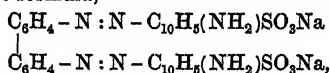

DYESTUFFS AND MORDANTS.—Until the year 1856, when Perkin discovered the first coal-tar dyestuff, the dyes employed in practice were, with few exceptions, of natural origin. As already mentioned, these have been largely driven out of use by the artificial products. There are various methods of classifying the various dyestuffs. The really scientific method is to divide them into classes according to their chemical constitution; but this is not convenient for practical purposes, and it is better to classify them into groups according to the methods employed in their application to the various textile fibres. In former days they were divided into natural and artificial dyes, but since many of the natural dyes can now be prepared artificially, and it has also been found that there is no essential difference in chemical constitution between the two classes, this method of division is really of little use. Another method still employed is to divide them into substantive dyes—those which can dye the fibres direct—and adjective dyes—those which require the use of other substances in order to fix them on the fibres in a satisfactory manner.

The substances employed in order to fix the adjective dyes on the fibre are known as 'mordants,' and the terms substantive and adjective dyes have been replaced almost completely by the newer terms direct and mordant dyes. The mordants in general use are either acid or basic in their properties. The chief acid mordants are tannic acid and various fatty acids, whilst the basic mordants are mainly metallic compounds, chiefly of the metals chromium, aluminium, and iron. The acid mordants are employed for fixing dyes of a basic character—e.g. the basic dyes; whilst the basic mordants are used to fix dyes of an acid character, such as the main class of mordant dyes. For practical purposes the dyestuffs now in use may be divided into the following nine classes: (1) Direct Cotton Dyes; (2) Basic Dyes; (3) Acid Dyes; (4) Mordant Dyes; (5) Sulphur Dyes; (6) Vat Dyes; (7) Insoluble Azo Dyes; (8) Oxidation Dyes; (9) Mineral Dyes. It must be understood that these classes of dyes are not all sharply defined from one another, as there are many dyes which seem to occupy an intermediate position between different classes.

The question as to what chemical or physical structure a substance must have in order that it

may be able to dye has given rise to countless theories, but has not yet been solved in a satisfactory manner. A discussion of the various suggested explanations would be beyond the scope of this article; but it may be stated that the general opinion seems to be that the dyeing of vegetable fibres is largely a matter of physical attraction, whilst the dyeing of animal fibres is more in the nature of a chemical action between the dyestuff and the fibre. When we note the great differences in structure and chemical composition between the two classes of fibres, it is easy to see that no simple theory is likely to explain the dyeing of all fibres. The natural wood dyes come into the market in the form of wood chips or raspings, or else in the shape of liquid or solid extracts obtained by extracting the colouring matter by boiling the wood with water. Most of the artificial dyes come as powders, some as pastes, and a few as solutions in various liquids. The more important methods of applying the various classes of dyes to the different textile fibres will now be considered.

1. DIRECT COTTON DYES.—These are sometimes called congo dyes or substantive cotton dyes. As their name indicates, they have the power to dye cotton without the use of a mordant. With few exceptions, they belong to the class known as azo dyestuffs, and are prepared by the 'diazo' reaction (see below). The first of this class was discovered by Bottiger in 1884, and named by him Congo Red. It has the formula,

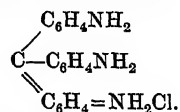

and is prepared by diazotising benzidine and coupling the product with naphthionic acid. Cotton is dyed by simply heating it in a solution of the dye, an addition of common salt or Glauber's salt being usually made in order to force more dye on to the cotton by diminishing the solvent action of the water. In many cases the dyeings obtained in this manner can be improved in fastness to light, washing, &c. by various methods of after-treatment. The three most important methods are: (1) treatment with metallic salts; (2) diazotising and developing; (3) coupling with diazo solutions. The first method is only applicable to certain of the dyestuffs, and consists in treating the dyed cotton for a short time in a hot solution of a metallic salt, such as copper sulphate or potassium bichromate. The second method is only suitable for dyes which contain one or more 'amido' (NH_2) groups. The dyed material is treated with a solution of nitrous acid (sodium nitrite and acid), in order to convert the dye into the diazo compound, and, after rinsing, the cotton is soaked in a cold solution of some suitable developer—e.g. beta naphthol. The reaction which takes place is similar to that occurring in the manufacture of the azo dyes and also in the dyeing of para red (see below), the original dye being converted into a new one on the fibre. These new dyes are usually darker in shade and faster than the original untreated dyeings.

Direct Cotton Dyes on Wool and Silk.—Many of these colours are well suited for dyeing wool or silk, and the dyeings so obtained are usually faster than those obtained on cotton with the same colours. Wool is dyed from a neutral bath, to which Glauber's salt is added. To exhaust the dye-bath better a small addition of acetic acid is frequently made. Many of the dyeings on wool can be rendered faster by after-treatment with metallic salts, as in dyeing cotton. Silk is dyed in the same manner as wool.

2. BASIC DYES.—These dyes, as their name indicates, are of a basic character; that is to say, they combine with acids to form salts. They can be

divided chemically into a large number of sub-classes, but practically all contain one or more amido groups, the hydrogen atoms of which are frequently replaced by organic radicles—e.g. CH_3 , C_6H_5 , &c. One of the oldest and most important of this class is magenta, which consists of a mixture of two closely related dyestuffs, one of which is para-rosaniline, and is given the formula:

Although cotton absorbs these dyes to some extent if heated in their solutions, it is more a stain than a dye, and the colour can be almost completely removed by washing. In order to get satisfactory dyeings with these colours on cotton the latter must first be mordanted (see above). The mordant usually employed is Tannin or Tannic Acid (q.v.), as this substance has the property of combining with basic dyes to form colour-lakes. The cotton is first soaked in a warm solution of tannin, of which it absorbs a portion, the amount of which depends on a number of factors, and the absorbed tannic acid (which would be removed by washing) is 'fixed' by passing the tanned cotton through a solution of some metallic salt—e.g. tartar emetic—by which the soluble tannic acid is converted into an insoluble metallic tannate. After washing with water, the mordanted cotton is dyed with the basic dyestuff from a heated bath, the final product on the fibre consisting of the double tannate of the metal and the dyestuff. Wool and silk can be dyed direct with basic dyes by simply heating them in the dye solutions. A little acetic acid is frequently added to the dye-baths to prevent the precipitation of the dye by any alkaline salts in the water.

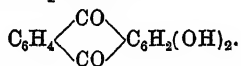

3. ACID DYES.—These dyes are acidic in properties, and form salts with bases, usually owing to the presence of hydroxyl (OH) or sulphonic (SO_3H) groups. Like the basic dyestuffs, the acid dyes can be divided into a number of sub-classes. Probably the most important of these classes is that of the azo dyes. These are formed by similar reactions to those employed in the preparation of para red (see below), but, unlike the latter, contain one or more sulphonic group which renders them capable of forming salts with alkalis, which salts are soluble in water. As an example, the dyestuff Orange 2 may be taken. This has the formula:

For cotton, these dyes are of little importance, as, with few exceptions, they cannot be fixed sufficiently fast upon the fibre; they form, however, the most important class of dyestuffs for wool. Although some of them will dye wool direct from a neutral bath, most of them give much better results if an acid—e.g. sulphuric—be added to the dye-bath. This liberates the 'free colour acid' from the dye, which is usually a sodium salt of a sulphonic acid, and these free acids are more strongly attracted by the wool fibre than their alkaline salts. Glauber's salt is usually added to the dye-bath in order to moderate the action of the sulphuric acid, and so give more 'even' dyeings. The dyeing is carried out at or near the boil. Silk is dyed with these colours in the same manner as wool. A number of the acid dyes have a particular chemical structure, owing to which they are able to combine with metallic salts—e.g. bichrome—to give colour-lakes. These lakes are usually insoluble, and the dyeings obtained with them are much faster than the direct dyeings. The dyeing is done as usual, and the metallic salt is added to the exhausted dye-bath,

and the boiling continued for some time. Such dyes are frequently known as acid mordant, or chrome dyes. The after-treated colours are in some cases quite different in shade from the original dyeings.

4. **MORDANT DYES.**—The basic dyes are really mordant dyes so far as cotton is concerned, but the name mordant dye is usually restricted in practice to those dyes which require the use of a mordant, whatever the fibre to which they are being applied. Many of these are hardly attracted at all from their solutions by the textile fibres, and even if they are taken up, the colours obtained are usually worthless and not fast. Many of them scarcely show any colour at all until they are combined with a suitable mordant to form a colour-lake. The mordants employed in practice are mainly metallic salts, and the same dyestuff will frequently give different coloured dyeings according to the particular metallic mordant with which it is combined. Dyes which show this property are sometimes called 'polygenetic dyes,' to distinguish them from the 'monogenetic dyes,' which give practically the same shade with different mordants. Most of the natural dyestuffs belong to the class of mordant dyes. The dyestuff alizarin may be taken as typical of the mordant colours. It has the formula given below, being a di-hydroxy anthraquinone:

It owes its mordant dyeing properties to the presence of the hydroxyl groups adjacent to a CO ('carbonyl') group. As most of the natural dyestuffs are dyed by similar methods to the artificial products, a brief description may be given here of the natural dyes still in use on the large scale. The natural dyes have lost greatly in importance since the discovery of the coal-tar colours, owing to the variety and purity of the shades given by the latter, and also to the greater ease and certainty with which they can be applied. The old idea as to the want of fastness of 'aniline dyes' no longer holds good as a general rule, as many of them give much faster shades than the natural dyes.

Natural Dyes.—The most important of the natural mordant dyes is Logwood (q.v.), which has never been completely replaced in black dyeing. It is a very cheap dyestuff, and gives a fine, bloomy black, which cannot be obtained with the artificial dyes at so low a price. It is dyed on wool, either on a chrome mordant or else with a mixed mordant of copper and iron. In pale shades it gives a blue on a chrome mordant, and a blue is also sometimes dyed on an alum mordant, but is not so fast as the chrome colour. It is dyed on cotton, with an iron mordant for blacks, but it has been largely replaced for this purpose by aniline black and the sulphur blacks. The most important of the remaining natural dyes are the following: Brazil-wood (q.v.), peach-wood, lima-wood, and sapan-wood; these are known as soft red-woods, and are chiefly the woods of various South American trees. They are dyed on the usual mordants, and give shades varying from red to violet, according to the particular mordant employed. Barwood and Camwood (q.v.) are hard red-woods, and give reddish-brown shades with the usual mordants. They are frequently used to 'bottom' woollen cloth before dyeing it with indigo. Fustic (q.v.), sometimes called 'old fustic' to distinguish it from another dyestuff, 'young fustic,' is the most important natural yellow dye, and gives shades varying from a yellow to an olive, according to the mordant. It is largely used along with logwood and other dyes, both natural and artificial. Madder (q.v.) has been practically driven out of the market by the artificial alizarin,

madder itself owing its dyeing properties to the presence of about $\frac{1}{2}$ per cent. of alizarin and allied dyestuffs. Quercitron bark, the bark from the *Quercus tinctoria*, gives similar shades to fustic. Weld, the stalks of *Reseda luteola*, gives bright yellow to olive shades. Persian berries, the fruit of the *Rhamnus infectiorius*, give yellow to brown shades, and are used in dyeing and printing. The most important dyestuff of animal origin is Cochineal (q.v.), which gives fine scarlet shades on a tin mordant. On alum crimson shades are obtained. Kermes and lac dye (see LAC) are also produced by various insects. They give somewhat similar but duller shades than those obtained with cochineal. They are little used in Britain.

The following natural dyes are not mordant dyestuffs in the true sense of the word, but are mentioned here for convenience: Archil (q.v.) and Cudbear (q.v.). These are produced from various species of lichens. They are dyed on wool direct from an acid, neutral, or alkaline bath, and are used to a considerable extent for red shades. Turmeric (q.v.), the root of *Curcuma tinctoria*, can be dyed direct on cotton, wool, or silk, and gives yellow shades. Catechu (q.v.) or cutch is the evaporated extract from various species of Acacia, and is largely employed for the production of fast brown shades on cotton. It is dyed on cotton with the addition of a little copper sulphate, and the dyeings are after-treated with bichrome solution in order to develop the colour fully. It consists of various bodies of a tannin nature, which appear to be oxidised to brown substances during the dyeing. It is largely used in the 'barking' of fishing-nets, in order to render them more durable. Other natural dyes of less importance are woad, young fustic, Annatto (q.v.), and Safflower (q.v.).

Mordant Dyes on Cotton.—Before cotton can be dyed with these colours it must be mordanted. The mordants employed are salts of alum, iron, chromium, and tin. If cotton be treated with solutions of neutral salts of the above metals, it only absorbs traces of the metals; but if easily dissociated acid or basic salts be used, the cotton can take up considerable quantities of the metals, which become fixed on the fibre in the form of basic salts, usually hydroxides. The acetates of alum and iron are largely employed, the cotton being impregnated with their solutions and then aged (see CALICO-PRINTING). During this process acetic acid is lost, and the mordants are fixed in the form of hydrates or basic salts. With the exception of alizarin, which is dyed on a very large scale on an alum mordant for the production of Turkey-red, and logwood, which is used in dyeing blacks on cotton, the other mordant dyes are of minor importance in cotton-dyeing, owing to difficulties in their application, and also to the expense of the process.

Turkey-red is a very bright and permanent colour on cotton; it was obtained till recently from madder, but now almost entirely from alizarin, by a special process. An oil mordant, as it is termed, is employed in combination with the fibre. Formerly a coarse olive-oil was made into an emulsion with a weak solution of crude pearl-ashes, through which the cloth was passed, then wrung out and hung up in a stove. The oil absorbs oxygen, and thickens into a varnish containing free fatty acids. The operation was repeated six or eight times. A Turkey-red oil is now sold which is chiefly the oleic acid of castor-oil in combination with ammonia, and of this oil the cloth requires only one or two applications. The oiled cloth is mordanted with alumina as usual, and then passed into the dye-bath, which is gradually raised to boiling. The bath is charged with alizarin,

and sumach or some other tannin substance is usually added in order to give a faster colour. The shade is finally brightened by boiling the dyed material in soap solution, to which chloride of tin is frequently added.

In dyeing logwood black on cotton the latter is first soaked in a tannin solution, and then in an iron liquor, so as to fix the iron mordant on the cotton in the form of tannate of iron. The cotton is finally dyed up with logwood.

Mordant Dyes on Wool.—The mordant dyes are very largely employed in the dyeing of fast shades on wool which cannot be obtained with the ordinary acid dyes. The mordants used for cotton are not suitable for wool, but the mordanting of the latter fibre is a much simpler process than the mordanting of cotton. The most important mordants for wool are bichromates of potash or soda, alum or aluminium sulphate, and, to a much less extent, sulphates of copper and iron and chlorides of tin. Bichrome is used for by far the greater number of mordant dyes on wool. Wool is mordanted by simply heating it to boiling in a solution of bichrome, to which additions of various 'assistants'—e.g. sulphuric acid, cream of tartar, oxalic acid, &c.—are frequently added to help the mordanting. After boiling for an hour or so, the wool is well rinsed with water, and then dyed in a fresh bath with the required mordant dyestuff. The dyeing is started at a moderate temperature, which is gradually raised to boiling. The other mordants are applied by similar methods, usually with the addition of tartar or oxalic acid.

Besides the above method of dyeing these colours, many of them may be dyed direct by the following methods. The wool is first dyed with the dye, and is then after-treated with the necessary mordant in the same manner as in the dyeing of the acid mordant dyes (see above). A third method which can be used for some dyes is to add both the dye and the mordant to the bath at the same time, so that they are both absorbed by the wool on heating. In this method some acid, such as acetic acid, is frequently added to the bath to prevent the premature formation of the colour-lake in the dye-bath.

Mordant Dyes on Silk.—Silk is usually mordanted by soaking it in strong, cold solutions of various salts, followed by a fixing operation. The dyeing is performed as in the case of wool.

5. SULPHUR DYES.—These dyes are with few exceptions insoluble in water, but can be dissolved in solutions of sodium sulphide, which apparently converts them into soluble reduction products. Cotton is dyed direct by these solutions, and on exposure to the air the soluble colour is in most cases oxidised back to the original insoluble form. The colour is boiled up with sodium sulphide and soda carbonate in order to dissolve it, and an addition of common salt is usually made in order to exhaust the dye-bath better. The dyeing is usually done at the boil, after which the cotton is rinsed and dried, but in some cases the dyed material must be submitted to an oxidising operation before rinsing to fully develop the colour. These colours are, as a class, extremely fast to light, washing, &c., but not to bleaching solution. Owing to the alkalinity of the dye-bath the above process is not suitable for dyeing wool or silk, but the latter are sometimes dyed with these colours by special processes. Very little is known as to the chemical constitution of these dyes, but they all appear to contain sulphur as an essential constituent.

6. VAT DYES.—The most important member of this class is Indigo (q.v.). Indigo is a product of the vegetable kingdom, and is produced from a number of plants chiefly belonging to the Indigofera family,

especially *I. tinctoria* and *I. arrecta*, which are cultivated in India, Java, and other tropical countries. Indigo is not present as such in the plant, but the latter contains a glucoside, 'indican,' which is decomposed by fermentation in the process of manufacture into indoxyl and a kind of sugar. This indoxyl on oxidation yields indigo. When ready, the plant is cut down, tied into bundles, and placed in large tanks of water to steep for some hours. A vigorous fermentation soon arises, which decomposes the indican and liberates the indoxyl, which dissolves in the water. The solution containing the indoxyl and other soluble matters is then run off into beating-tanks, in which it is beaten either with mechanical beaters or else by hand, in order to bring it into intimate contact with the air, and so oxidise the indoxyl to indigo, which sinks to the bottom, and is collected, boiled with water, strained on canvas filters, pressed in presses, cut up into small blocks, and dried gradually in the air. The product obtained in this manner is not the pure dyestuff, and usually contains only about 62 per cent., or even less, of the real indigo blue dyestuff, or 'indigotin,' as it is called, the remainder consisting of indigo red, or 'indirubin,' indigo browns, indigo glutin, &c. The part which these so-called impurities play in the dyeing operation is a matter of considerable controversy, but they are sometimes stated to give richer dyeings than the pure indigotin. At the present day indigotin is very largely manufactured artificially from naphthalene and other coal-tar products. During the last few years a large number of new vat dyes have been placed on the market, some of which are derivatives of indigo, whilst others only resemble it in the method of their application. Indigotin or indigo blue has the formula:

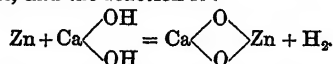

The vat dyes are all insoluble in water, but can be converted by reducing agents into leuco compounds, which are soluble in alkalies. The textile fibres absorb these leuco bodies from their solutions, and on exposing the dyed materials to the air the soluble leuco dyes are oxidised back to the original insoluble dyestuffs upon the fibre. The solutions employed to reduce these dyes are known as 'vats,' and the name 'vat dyes' is used to designate the whole class.

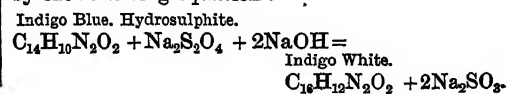

A great number of different vats are employed for reducing indigo, but only a few of these are of much importance. The chief vats used for cotton-dyeing are: (1) the copperas vat; (2) the zinc-lime vat; (3) the hydrosulphite vat. In the first the finely ground indigo is mixed with a warm solution of sulphate of iron, and lime is added. The copperas is converted by the lime into ferrous hydrate, which oxidises, at the expense of the water, to ferric hydrate, liberating hydrogen, which reduces the indigo blue into its leuco compound, which is named indigo white, and dissolves in the alkaline solution. The reduction of the indigo is illustrated by the following equation:

In the zinc-lime vat the copperas is replaced by zinc-dust, and the reaction is:

The reaction in the hydrosulphite vat is expressed by the following equation:

The reduction is usually carried out at a temperature of about 50° C. in a strong vat, which is then added to the necessary quantity of water in the dye-vat proper. Cotton is dyed cold, being entered into the solution of indigo and worked below the surface for some time; it is then lifted, squeezed, and exposed to the air in order to oxidise the leuco indigo which has been absorbed by the fibre. This constitutes one 'dip,' but if a darker shade is required a second or more dips are given. In dyeing wool with vat dyes great care must be taken to avoid the fibre being injured by the alkaline liquors. The chief vats for wool-dyeing are: (1) the fermentation vat; (2) the hydrosulphite vat. In the first of these the reduction is effected by means of hydrogen produced by certain ferments. The vat contains indigo, lime, and a number of fermentable substances, such as bran, sugar, woad, madder, &c. The vat is heated, and a strong fermentation soon commences, which after a time reduces the indigo. The fermentation vat requires great experience in order to work it properly, but is still largely employed in wool-dyeing. The dyeing is carried out hot, and a longer immersion is needed than in the case of cotton; like the latter the dyed material must be exposed to the air after dyeing. The hydrosulphite vat is also suitable for wool, and is prepared as for cotton except that less alkali is taken. Instead of using hydrosulphite ready prepared, the dyer frequently prepares it himself in the vat from zinc-dust and sodium bisulphite. Most of the other vat dyes can be dyed on cotton by similar methods to those used for indigo, but in some cases hot baths must be employed. The hydrosulphite vat is most used. Many of these dyes are also suitable for wool.

7. INSOLUBLE AZO DYES.—This is a very small class of dyestuffs, but includes the very important one known as paranitraniline red, or para red. Being insoluble in water, these dyes cannot be applied by the usual methods, but must be actually prepared on the fibre itself. Their use is restricted to the dyeing of vegetable fibres, as the alkaline liquids employed would injure animal fibres. In dyeing para red, the cotton is first impregnated with a solution of beta naphthol in caustic soda, carefully squeezed and dried, and then passed through a solution prepared by diazotising paranitraniline with sodium nitrite and acid. Combination takes place between the diazo compound and the naphthol, and the dyestuff is formed upon the fibre. It is usual to add some fatty substance, such as Turkey-red oil, to the naphthol prepare in order to give brighter and faster colours. As this chemical reaction is typical of the manufacture of all the azo dyes, the equations are given in full below.

The diazo chloride thus formed then unites with the sodium salt of the naphthol, ($\text{C}_{10}\text{H}_7\text{ONa}$), to form the dyestuff thus:

which is the insoluble para red.

By replacing the paranitraniline in the above reaction by other amido compounds different colours can be produced; e.g. if the diazo chloride of alpha naphthylamine be coupled with beta naphthol in the same manner as given above, a fine claret colour is obtained, which is known as naphthylamine claret, or Bordeaux, and is very largely employed in calico-printing. Para red is a very fast dye, and on account of its much lower cost has to a considerable extent replaced Turkey-red in the dyeing of red shades on cotton yarn and pieces. Besides the two dyes given above, there are a considerable

number of other dyes of the same class, but they are of much less importance than the two named, and although used to some extent in printing, are seldom employed in dyeing.

8. OXIDATION DYES.—The most important colour of this class is aniline black. This dye, which has been in use for the last fifty years, is insoluble in water and other ordinary solvents, and requires to be manufactured on the fibre itself by a special process. It is an oxidation product of aniline, but although a great deal of work has been done on it, its chemical constitution is not yet quite clear. There are various processes employed in practice, one of which, called the single-bath black, is described below. The dye-bath is prepared with aniline dissolved in hydrochloric acid, so as to form the soluble hydrochloride, water and bichromate of soda or potash, together with more acid, in order to liberate chromic acid from the bichromate. The cotton is entered and worked for some time in the cold bath, in order to become thoroughly impregnated with the mixture; the temperature is then gradually raised to near the boiling-point. The cotton first becomes green, owing to the formation of an intermediate oxidation product known as emeraldine, which on further oxidation is converted into the black. Aniline black is a very fast dye, and is dyed on an enormous scale. The other dyes of the same class are of much less practical importance. Aniline black is not dyed on wool.

9. MINERAL DYES.—These are of minor importance, and are practically only applied to cotton. The most important are iron buff, Prussian blue, and chrome yellow. Iron buff is dyed by padding the cotton in a solution of 'nitrate of iron,' and then passing it through a solution of soda or lime water. The colour is produced by the deposition of ferric hydroxide on the fibre. Chrome yellow can be dyed by padding the cotton in a solution of a lead salt, and then passing the cotton through a solution of a bichromate, in order to form the insoluble yellow lead chromate on the fibre.

Dyeing of other Vegetable Fibres.—Linen and other vegetable fibres are dyed by similar methods to those used for cotton.

UNION DYEING.—Owing partly to the high price of wool, a very large amount of cloth is now manufactured from mixtures of cotton and wool. Because of the different dyeing properties of these fibres, special methods have to be employed in dyeing such materials. A method formerly much used was first to mordant the piece with tannin, which was chiefly absorbed by the cotton, and then to dye with basic dyes, which dyed both the wool and the mordanted cotton. Another method is to dye the piece first in the ordinary manner with an acid dye, which mainly dyes the wool, and then to dye the cotton in the piece with a direct cotton dye at a moderate temperature, or else to dye the cotton with a basic dye after first mordanting it with tannin. By a suitable choice of dyes two-coloured effects can be produced by this method. If faster dyeings are required, mordant dyes can be used for the wool and sulphur dyes for the cotton. The above methods all require two or more dyeing operations, and they have been largely replaced in recent years by the use of the direct cotton dyes, many of which dye both wool and cotton in approximately the same shade. Any difference in shade is corrected by the addition of suitable dyes to the bath. Materials consisting of wool and silk or cotton and silk are dyed by modifications of the above processes.

MACHINERY USED IN DYEING.—The textile fibres are dyed in all the various stages of their manufacture—e.g. loose or raw material; yarn and woven pieces. The material is dyed in the loose form when a very thorough through dyeing of the

individual fibres is required, or when two or more different coloured materials have to be spun together into a mixed yarn. As the material so dyed has to pass through all the subsequent manufacturing operations, the dye must be very fast, as otherwise it would be more or less removed by the severe treatment to which it is subjected. Yarn-dyeing is chiefly employed when different coloured yarns are required for weaving into multicoloured fabrics. Dyeing in the piece is practically limited to cases where only one colour is required on the material, but if the cloth consists of more than one textile fibre—e.g. a mixture of cotton and wool—two-coloured effects can often be obtained even in the piece. The usual method of dyeing loose material is in large hemispherical copper pans, which are sometimes heated directly over the fire, but more often by means of steam jackets or coils. The material is worked about in the dye-liquor by means of poles, in order to obtain even dyeings, but this method causes considerable felting or knotting of the fibres and loss in the later operations of combing, &c. To avoid this, open-pan dyeing has been largely replaced by machine-dyeing, in which the loose material is packed in closed holders, and the dye-liquor is forced through either by means of a pump or else by air-pressure. As the material remains stationary, there is no risk of felting. Yarn is usually dyed in the hank-form in rectangular wooden vessels heated by steam-pipes, the hanks being suspended from sticks which lie across the top of the vat. The hanks are turned every few minutes by hand, in order to alter their point of support and obtain even dyeings. As the hand-work is very heavy, a number of machines have been designed to effect this mechanically. Yarn is sometimes dyed in the form of warp ready for the loom, the bundle of warp-threads being carried through the dye-liquor by means of guiding-rollers until the dyeing is completed. Of recent years 'cop dyeing' has come largely into use for cotton. The cops are placed on perforated spindles, and the dye-liquor is forced through them by pressure. This method avoids the loss caused by reeling into hanks, dyeing, and winding back on to the cops for the weaving process. Cotton pieces are mostly dyed in the 'jigger,' which is a dye-vat having a rectangular top and a V-shaped vertical section. The pieces are beamed on a roller placed at one side of the vat, and pass down over guide-rollers fixed at the lower part of the V-shaped portion, and then up to another beaming-roller placed at the opposite side of the vat to the first. The lower part of the vat contains the dye solution, and the pieces, which may be several hundred yards in length, are run backwards and forwards through the liquor from one beaming-roller to the other. Wool pieces are usually dyed on winch-machines, as they would not stand the strain in the jigger. The winch-machine consists essentially of a dye-vat heated with steam coils, over which is placed a winch or reel. A number of pieces are joined together and thrown over the reel, the loose ends being sewn together so as to form an endless band. The reel is revolved by power, and the pieces circulated through the dye-liquor until sufficiently dyed.

In dyeing with mordant colours, the mordanting is usually carried out in similar machines to those used for the dyeing. The dyeing material is frequently well rinsed with water in the same machine in which it has been dyed, but yarn is usually washed on special washing-machines. After washing, the wet material is well squeezed or hydro-extracted, according to its state of manufacture, and is then dried, commonly by hot air. Piece goods as a rule require stretching after dyeing to counteract the shrinkage caused by the heat and

liquids. The dried material has finally to pass through a number of finishing operations in order to render it fit for the market, but a discussion of these would be beyond the scope of this article.

Hubner, *The Bleaching and Dyeing of Vegetable Fibrous Materials*; Green, *The Organic Colouring Matters* (1908); *Journal of Society of Dyers and Colourists*; *The Dyer and Calico Printer*, *Die Farber-Zeitung*, *Revue Générale des Matières colorantes*; Matthews, *Laboratory Manual of Dyeing and Textile Chemistry* (1909); Dreaper, *The Chemistry and Physics of Dyeing* (1906).

Dyer, SIR EDWARD, poet, courtier, and diplomatist, was born at Sharpsham Park, Somersetshire (Fielding's birthplace) about 1545. He seems to have studied at Oxford, but took no degree. After some time spent in travelling on the Continent, Leicester sought to advance him at court as a rival to Sir Christopher Hatton in Elizabeth's favour, which he more than once lost and regained. Court life seems to have been irksome to him, for he 'would not stoop to fawn.' In 1584 and 1589 he went on diplomatic missions to the Low Countries and to Denmark, and in 1586 was commissioned to inquire into crown lands illegally alienated. He was knighted in 1596, and made chancellor of the Order of the Garter; and in 1607 he died. He was said to be addicted to alchemy, 'esteemed by some a rosi-crucian, and a great devotee of Dr Joh. Dee and Edw. Kelly.' Dyer was a friend of Edmund Spenser, Sir Philip Sidney, and Fulke Greville. Sidney bequeathed his books to be divided between him and Greville. Among his contemporaries his reputation was high as a poet, especially an elegiac poet; but little has come down bearing his name, and of that little it was long difficult to know what was truly his. Poems ascribed to him in one collection were elsewhere recognised as the work of Lodge or Breton; but in 1872-76 Dr Grosart did his best to identify and edit (in the 'Fuller Worthies Library' *Miscellany*, iv.) all Dyer's extant work—a dozen pieces in all. 'My Mind to me a Kingdom is,' set to music by William Byrd in his *Psalms, Sonnets, and Songs* (1588), is almost certainly his, and on it rests his claim to immortality.

Dyer, GEORGE, antiquary and scholar, well known to readers of Charles Lamb, was born in London, 15th March 1755, and educated first at Christ's Hospital, and afterwards at Emmanuel College, Cambridge, which he entered in 1774. He took his degree of B.A. in 1778. During the next fourteen years he was variously engaged, chiefly at Cambridge, as tutor and usher, but he finally settled in London in 1792. Here he devoted himself principally to literature, and produced, among many works of less note, the *History of the University and Colleges of Cambridge* (1814), and *Privileges of the University of Cambridge* (1824). He also contributed largely to the *New Monthly* and *Gentleman's Magazine*, made indexes, and corrected for the press. He contributed 'all that was original' to Valpy's classics, 141 volumes (1809-31), but became blind when his work was done. The incident of his walking into the New River and being nearly drowned is chronicled by Charles Lamb in his essay 'Amicus Redivivus.' He died in Clifford's Inn, 2d March 1841. Dyer was a man of remarkable straightforwardness and honesty of character, qualities which are everywhere discernible in his works. He was destitute of humour, slovenly in dress and in his home surroundings. 'For integrity and single-heartedness,' Lamb ranked him 'among the best patterns of his species.' He was also a poet, although now forgotten, and never famous.

Dyer, JOHN, an English poet, was born about 1700, near Llandilo, in Carmarthenshire, and

educated at Westminster. On the death of his father, a solicitor, he abandoned law, and took to art, rambling over South Wales and the English country near. In 1727 he published his poem of *Grongar Hill*, remarkable for simplicity, warmth of feeling, and exquisite descriptions of natural scenery, which it was much more a merit for a man to see then than now. He next travelled in Italy, returned in bad health to publish a second poem, the *Ruins of Rome* (1740), took orders, and became vicar of Catthorpe in Leicestershire in 1741, which he exchanged later for the Lincolnshire livings of Belchford, Coningsby, and Kirkby-on-Bain. He died in 1758. The year before his death he published *The Fleece*, an unpretentious didactic poem, which had the honour to be praised by Wordsworth in a sonnet. His poems were edited by Edward Thomas in 1903.

Dyer, THOMAS HENRY, an industrious archaeologist and historian, born in London, 4th May 1804. In early life he was engaged in the West India trade, but he ultimately devoted himself to literature, and qualified himself as an authority on classical antiquities by extensive travel on the Continent and prolonged study of the topography and antiquities of Rome, Pompeii, and Athens. In 1865 he was made LL.D. by the university of St Andrews. His works are a *Life of Calvin* (1850), *History of Modern Europe* (4 vols. 1861-64; revised and continued by Hassall, 1901-2); *History of the City of Rome* (1865), *History of the Kings of Rome* (1867), *Ruins of Pompeii* (1866; 2d ed., substantially a new work, entitled *Pompeii: its History, Buildings, and Antiquities*, 1868), and *Ancient Athens* (1873), besides articles in the *Classical Museum* and *Smith's Dictionary of Biography and Geography*. He died at Bath, 30th January 1888.

Dyer, SIR WILLIAM TURNER THISELTON, botanist, born at Westminster, 28th July 1843, studied at Oxford, was professor at Cirencester and in the Royal College of Science in Ireland, and director of Kew Gardens (1885-1905). He edited a number of floras.

Dyer's Weed, a name given to various plants which have yielded dye-stuffs, especially Weld (q.v.), Woad (q.v.), and dyer's broom (see BROOM).

Dyfed. See PEMBROKESHIRE.

Dying Declaration. See DECLARATION.

Dyke, or DIKE, an artificial mound along the bank of a river or seashore, erected for the purpose of preventing inundation; but *dyke* is also used in the sense of *ditch*, another form of the same word (Old English *dīc*; modern Scots *dyke*, a boundary wall of stone or turf; cognate with German *teich*, a pond). Dykes or embankments, in some form or another, are in use in most low-lying countries, as in the English Fen Country and along the Lower Mississippi (q.v.). But the classical land of dykes is Holland, where as early as 10 B.C. the Roman commander Drusus made embankments. Beside the river-dykes, and those which help to keep the *polders* (see POLDER) drained, the kingdom of the Netherlands possesses, where the shores are not defended by sand-dunes, many hundreds of miles of sea-dykes, erected and maintained at enormous cost. One, the West Kappel dyke, is 12,648 feet long, and 23 feet high, with a seaward slope of 300 feet; it is protected by piles and stone-work, and has a road and a railway on its top. Great destruction has been brought about by the bursting of dykes

in Holland; sometimes the Dutch dykes have been deliberately broken down for military purposes, as when in 1574 the Prince of Orange raised the siege of Leyden by breaking down the dykes, flooding the country, and drowning many of the besieging Spaniards. Modern illustrations of the fearful damage caused by the bursting of dykes are those which destroyed Szegedin, in Hungary, in 1879, and the flooding of a vast area in China by the inundation of the Hoang-ho in 1887. For various kinds of embankments, see CANAL, RAILWAY, LEVEE, WATER-WORKS, HAARLEM, BEDFORD LEVEL.

Dykes and Veins. Igneous rocks which rise in even-sided, more or less vertical, wall-like sheets are called dykes, from the common Scots word for a wall (see the article above). The term vein is applied to the more irregular, winding, branching, and generally smaller intrusions. Dykes and veins are of common occurrence in the cones of existing volcanoes, where they appear to have been injected chiefly from below. Occasionally, however, the rents occupied by dykes would seem to have been filled from above by an overflowing stream of lava. The crystalline rocks of which dykes are composed are of various kinds. In Scotland, where dykes are abundantly developed, the rock is chiefly some variety of basalt-rock. These basalt-dykes vary in thickness from a foot or less up to 100 feet and more, and in length from apparently only a few yards up to many miles. Sometimes they cut across rocks which have yielded more readily than themselves to the denuding agents, and hence they form prominent features in a landscape, stretching like great wall-like ramparts across low-lying undulating tracts; when, on the other hand, they traverse strata which are less readily eroded than themselves, they frequently form deep trench-like hollows. Sometimes they have come up along lines of faults; but more frequently they appear simply to occupy great rents which are not accompanied by any vertical displacement of strata. They generally run in approximately straight or gently undulating lines; but occasionally they follow a more zigzag course. The rock of a dyke is usually jointed at right angles to its direction, and now and again this jointing gives rise to fine prismatic columns. In the centre of the dyke the rock is more markedly crystalline than towards the sides, where it is often compact, and its point of junction with the walls of the rent in which it lies are not infrequently coated with a skin of volcanic glass. Vesicular cavities frequently appear in the centre of a dyke, and finer pores are often distributed through the rock near the sides. As a rule, the strata are not much affected at their junction with a dyke—the alteration seldom extending beyond a foot or two. When the dyke, however, is very thick, say 100 feet or so, the adjoining rocks are often considerably baked—limestones being rendered crystalline, while coals are converted into a kind of coke, shales are porcelainised, and sandstones changed into quartzite. Sometimes, too, the strata are much smashed and jumbled, and their fragments enclosed in the marginal areas of the intrusive rock.

In regions where fissure-eruptions have taken place, the dykes are often branching and irregularly ramifying—the rocks being traversed by a perfect network of dykes and veins, anastomosing with and crossing each other at all angles. Good examples occur in the western islands of Scotland, the Farøe Islands, and Iceland. Veins are frequently very numerous in the neighbourhood of great masses of granite, from which, indeed, they proceed. It is remarkable that the rock of such veins is frequently finer grained than the granite from which it comes, and often passes into quartz-

porphyry or Felsite (q.v.). Granite itself is also very commonly traversed by peculiar dykes and veins, some of which are more coarsely crystalline, while others are finer grained, than the granite itself. These veins are so closely welded into the granite, their crystals indenting the surrounding rock, that it is obvious they were formed at a time when the granite was only partially consolidated. It seems probable that they were injected before the granite had quite solidified. They are known as 'contemporaneous' or 'segregation' veins; but their precise mode of formation is still very obscure. Occasionally dykes of fragmental matter occur, as in the Sidlaw Hills, the hills of Ayrshire, and the Cheviots in Scotland. They have been observed also in the Canary Islands. Such dykes vary in width from a foot or two up to many yards. They seem only to occur in association with other volcanic rocks, and generally to indicate the proximity of some volcanic vent. The fragmental materials are angular, and form a breccia or agglomerate of volcanic rocks alone, or of these and various derivative rocks; hence they are termed *agglomerate dykes*. See IGNEOUS ROCKS.

Dykes, JOHN BACHUS, composer, was born at Hull, 10th March 1823, graduated at Cambridge, was ordained in 1847, and was appointed precentor of Durham cathedral in 1849. In 1861 he received the degree of Mus. Doc. from the university of Durham, and in 1862 was presented to the vicarage of St Oswald's in that city. An earnest High Churchman, he became involved in a controversy with Dr Baring, his diocesan. He died 22d January 1876. Dr Dykes was a joint-editor of *Hymns Ancient and Modern*, and composed, besides many services and anthems, a number of hymn-tunes, most of which are to be found in all English collections. Among these are 'Lead, Kindly Light,' 'Nearer, my God, to Thee,' and 'Jesus, Lover of my Soul.' See *Life by Fowler* (1897).

Dymoke, the name of a Lincolnshire family who exercised the offices of Champion (q.v.) and Standard-bearer of England from the coronation of Richard II. to that of George IV., after which the champion's ceremony was dropped, though the standard-bearer continued to play his part. These offices passed in 1875 to a collateral branch of the family. See Samuel Lodge, *Scrivelsby, the Home of the Champions; with some Account of the Marmion and Dymoke Families* (1893).

Dympna, SAINT, an Irish princess doubtfully referred to the 7th or the 9th century, is said to have fled to Ghel in Belgium from the incestuous passion of her father, who followed her thither and slew her. She is patroness of the insane.

Dynamics is the science which treats of *matter and motion*. The term *Mechanics* (q.v.) has been, and still is, much employed to denote this science, but its use in this way is not justifiable. *Kinematics*, the science of *motion*—i.e. of *space and time*—does not take account of *what moves*, nor of *what cause* produces the motion. In dynamics, the nature of the moving body and the cause of its motion are both considered. The whole science is based upon Newton's Laws of Motion, which are as follows: (1) Every body continues in its state of rest or of uniform motion in a straight line, except in so far as it is compelled by force to change that state; (2) change of momentum is proportional to force, and takes place in the straight line in which the force acts; (3) to every action there is always an equal and contrary reaction. Definitions of the principal terms used in the science are given below.

The *mass* of a body—i.e. the quantity of matter which it contains—is proportional to its volume

and density conjointly, the *density* being the quantity of matter contained in unit volume. If *V* be the velocity of a moving body, the mass of which is *M*, the quantity *MV* is termed its *momentum*; and similarly, if *A* be the acceleration of velocity, *MA* is called the *acceleration of momentum*. The quantity $\frac{1}{2}MV^2$ (which represents the work done on a body of mass *M*, originally at rest, in order to produce in it the speed *V*) is called the *kinetic energy* of the body.

Force is defined as any cause which alters a body's state of rest or of uniform motion in a straight line. A force is measured (in accordance with Newton's second law) by the momentum which it produces in unit time—i.e. by the quantity *MA*. It is completely specified when its place of application, its direction, and its magnitude are given. Hence (and since every force produces its own change of momentum in a body quite independently of the action of other forces) forces are compounded and resolved in the same way as accelerations and velocities (see *VELOCITY*). A force does *work* when it moves a body in the direction in which it acts, and the work done is measured by the product of the force into the distance through which it moves the body, or, as has been already remarked, by the kinetic energy produced. A pair of equal and oppositely directed forces acting so as to rotate a body about an axis is termed a *couple*, and the product of either of the forces into the distance between their lines of action is called the *moment* of the couple.

In many cases of motion the moving body, though of finite dimensions, may be treated as if it were a mere material particle. Thus there is the dynamics of a particle. This subject is further subdivided into *statics* and *kinetics* of a particle according as the particle is or is not in equilibrium under the forces. The condition for equilibrium is that the sum of the resolved parts of the forces in *any* direction is zero; but, because of the tri-dimensional character of space, it is sufficient to show that the sums of the resolved parts in any three non-coplanar directions are zero. When motion occurs, three cases arise according as the motion of the particle (1) is limited to a given curve, (2) is limited to a given surface, or (3) is unlimited. Simple examples are those of particles (1) falling under the action of gravity, or sliding under gravity on a smooth or rough surface; (2) projected at any inclination under gravity, or revolving around an attracting centre (in both these cases the surface to which the motion is confined is a plane). In all these cases, in accordance with the second law of motion, the resultant of the forces acting on the particle is equal to the acceleration of momentum; and whenever two or more particles mutually influence each other, the third law is required, in addition, completely to determine the motion. When two smooth spheres impinge upon one another, and remain in contact, their common speed is that of their Centre of Inertia (q.v.) before impact. If they separate again, the centre of inertia retains its previous motion, while the relative speed of separation is always a definite fraction (less than unity) of the relative speed of approach. Thus the motions are determinate.

A moving body, though it cannot always be considered to be a mere particle, may often be regarded as rigid. We have thus the statics and kinetics of a rigid solid. The three necessary conditions for equilibrium of a particle are here insufficient, as the body may rotate. The other conditions are that the sums of the moments of the forces about any three non-coplanar axes shall vanish. When the rigid body moves under the action of forces, it is sufficient to know the motion of the centre of mass (which is a case of kinetics of a particle),

and the *moments of inertia* of the body about three non-coplanar axes through the centre of mass. The moment of inertia about any axis is the sum of the products of the mass of each particle of the body into the square of its least distance from the axis. When a body rotates about an axis, it is always possible to find a distance such that, if the whole mass of the body were condensed at that distance from the axis, its moment of inertia would be the same as that of the actual body. This distance is called the *radius of gyration*. The quantity MAR^2 , where R is this radius, A is the angular acceleration, and M is the mass, is the rate of increase of moment of momentum; and, by the second law, this is equal to the moment of the resultant couple about the axis of rotation.

The case of equilibrium of a flexible cord or chain is readily treated by means of the consideration that the difference of the horizontal parts of the tension at each end of any link is zero, while the difference of the vertical parts is equal to the weight of the link; and at least one case of motion of a flexible cord can be treated by an elementary statical method (see WAVE). The subject of dynamics of an elastic solid is of great complexity. For a slight discussion of the more elementary parts, see ELASTICITY and RIGIDITY.

Dynamite and other 'High' Explosives.

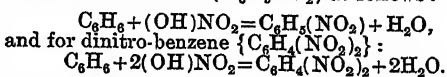

As early as 1534 mention appears in a work termed *Buchsenmeysterei*, printed at Frankfort-on-the-Main, of an explosive liquid formed by a mixture of six parts of nitric acid, two parts of sulphuric acid, three parts of liquid ammonia, and two parts of oleum benedictum—a crude tar-oil. Next there is a description of aurum fulminans, or fulminating gold, in *Pepys's Diary*, under the date November 11, 1663, as a powerful explosive; while Berthollet, in 1786, discovered potassium chlorate ($KClO_3$), and endeavoured, until a disastrous explosion occurred, to use it to form a gunpowder. In 1800 Howard investigated the fulminates, and was severely injured while doing so. The articles on Gun-cotton and Nitro-glycerine give further details of the progress in the discovery of explosives. The wonderful results obtainable by detonation of nitro-glycerine and gun-cotton, as compared with the explosion of gunpowder, gave an immense impetus to research into the nitration of many organic substances, with the result that the number of explosive compounds and mixtures known is now very great, and grows annually.

The meaning of the term detonation has been explained under Gun-cotton, but it will be well to touch briefly here on the fundamental difference between an explosive *mixture*, such as gunpowder containing no ingredient which is itself detonatable, and an explosive *compound*, such as nitro-glycerine, and the other nitro-compounds which will be dealt with in this article. This difference is due to the very intimate and regular contact of the constituent atoms of the molecule of an explosive compound and the comparative coarseness of the most carefully made mechanical mixture. The explosive combination of the various elements of the compound can therefore take place enormously faster than can be the case with the constituents of a mixture such as gunpowder, which is quite incapable of detonation. If, however, the potassium nitrate of gunpowder be replaced by potassium chlorate (which can be detonated by itself, though with difficulty), a detonating explosive is produced. The violence of this and other detonating *mixtures* of a similar character will, however, be affected by the intimacy of the mixture of the ingredients. Detonating explosives are termed 'high' explosives, and are of course only used for disruptive purposes. Their special feature is the rapidity with which the

wave of detonation will traverse them. This varies considerably with the density of the charge and the initial detonating impulse. In the most favourable circumstances all the detonating compounds which are usually employed have velocities of detonation of over 20,000 feet per second. No compound or mixture would rank as a high explosive which has a lower velocity of detonation than about 6000 feet per second. Too much must not be made of this feature, however; the heat and volume of gas produced on detonation are the measures of an explosive's power. Velocity of detonation enables that power to be exerted with the utmost rapidity and violence.

The number of organic bodies capable of nitration to produce explosives is very large, but, as the result of experiments, the majority have been rejected as too expensive, as requiring too much purification, as giving too sensitive compounds, or as requiring an undue amount of nitration to obtain the best results. As a consequence, the nitro-compounds in practical use are not very numerous, though the number of explosives, with various fancy names, formed by mixing them together (with or without the admixture of non-explosive materials) is considerable—some sixty or more being mentioned in the Annual Reports of H.M. Inspectors of Explosives as actually manufactured or sold in the British Isles. To mention the more important of the nitro-compounds, there are, of the cellulose class, gun-cotton (soluble and insoluble); and of the glycerine class, nitro-glycerine. The cellulose and glycerine classes, it may be remarked, are sometimes classed together as alcohols, owing to the similar formation of their nitrates (see GUN-COTTON and NITRO-GLYCERINE), as compared with the true nitro-substitution products about to be mentioned. These latter are obtained from the so-called aromatic hydrocarbons, benzene (C_6H_6), toluene (C_7H_8), and naphthalene ($C_{10}H_8$), and the derivatives of the first two by hydroxyl (OH) substitution, phenol (C_6H_5OH), and cresol (C_7H_7OH), to mention only some of the more important.

These compounds when treated with mixtures of nitric and sulphuric acids produce nitro, dinitro, trinitro, and in some cases tetranitro compounds. As in the case of gun-cotton and nitro-glycerine, the sulphuric acid does no more than take up the water formed by the chemical reaction, and so maintains the strength of the nitric acid. The action of the nitric acid (HNO_3) on these hydrocarbons is usually explained by assuming that one or more of the hydrogen (H) atoms in the hydrocarbon is replaced by the nitril group (NO_2), with the formation of water (H_2O), in combination with the hydroxyl (HO) of the nitric acid, which last can be written $(OH)NO_2$ instead of HNO_3 . Thus in the case of benzene (C_6H_6) we have the formation of nitro-benzene ($C_6H_5NO_2$) as follows:

Trinitro-benzene, $C_6H_3(NO_2)_3$, can be similarly formed by a large excess of mixed acids. It is not much used.

The specially important compounds of this group are dinitro-benzene, already mentioned, trinitro-toluene, $C_7H_7(NO_2)_3$, and trinitro-phenol (picric acid), $C_6H_3(NO_2)_3OH$. All the nitro-substitution compounds above mentioned are deficient in the oxygen needed for the complete combustion of their carbon (C), and on detonation by themselves give off dense black smoke. They are therefore usually mixed with some oxidising substance when used for explosives. They are very inert, and need powerful detonators to produce detonation. Unless strongly confined they will not explode on ignition.

A highly important compound also is ammonium nitrate (NH_4NO_3). This compound, itself a mild explosive when detonated, is very largely used mixed with other more powerful explosives—firstly, as a reservoir of available oxygen to ensure that the actively poisonous gas carbon monoxide (CO) shall be converted, as far as possible, to the less objectionable carbon dioxide (CO_2), which, while it does not support life, is not actively poisonous if inhaled; secondly, to cool down the gases of explosion (as its decomposition absorbs heat), and thus produce a ‘permitted explosive,’ which is one which passes the British Home Office test, prior to use in fiery mines, of not causing, by its detonation, an explosive mixture of coal-gas and air to explode. Ammonium nitrate is a constituent of some 70 per cent. of these permitted explosives. As it is highly deliquescent, the mixtures in which it is used must be contained in waterproofed cartridges. A mixture of tri-nitro-toluene with ammonium nitrate in proportions varying from 60 to 20 per cent. of the former to 40 to 80 per cent. of the latter, is now the high explosive largely used for shell and bomb filling in the British service. The mixture is termed ‘Amatol.’ Usually the mixture with 20 per cent. of tri-nitro-toluene is used, and is described as ‘Amatol 80/20.’ When closed up in a shell its hygroscopicity is unobjectionable. With 50 to 60 per cent. of tri-nitro-toluene, and heated up above the melting-point of the latter, and kept well mixed, the mixture can be poured into shell, as can be done with tri-nitro-toluene alone (see below); but with less than about 50 per cent. of tri-nitro-toluene the mixture is put into the shell as a powder, and consolidated by suitable means to a density of about 1.45. The mixture of the two ingredients can be effected by milling cold under rolls, or by mixing with stirrers at a temperature of about 100°C . For mines ammonium perchlorate (NH_4ClO_4), mixed with a combustible such as wood-meal, was used largely in the war of 1914–18. This is a powerful high explosive. Explosives with potassium and ammonium perchlorate bases, mixed with nitro-compounds, or with a combustible only, are used to a considerable extent on the Continent.

Nitro-glycerine, gun-cotton, and the other explosives mentioned, except Picric Acid (q.v.), which is usually employed by itself, may be, and are, mixed together to form special explosives, but the following substances are often used in the mixtures, viz. barium, potassium, and sodium nitrates, as absorbents of nitro-glycerine, instead of the absolutely inert kieselguhr (see below); and when this is done, charcoal, wood-pulp, or wood-meal is added for combustion by the oxygen they contain. See GUNPOWDER.

The composition of some characteristic specially named explosives will now be given.

Dynamite.—Nitro-glycerine 75 per cent., kieselguhr 25 per cent. Kieselguhr is a silicious earth formed chiefly of the minute silicious cells originally containing Diatoms (q.v.), a group of plants found in water, especially in cold climates. The cells, being porous, absorb the nitro-glycerine. Although the parent of all high explosives, this form of dynamite has been superseded by the more powerful forms mentioned below.

Blasting-Gelatine.—Nitro-glycerine 93 per cent., nitro-cotton 7 per cent. This is probably the most powerful explosive in existence. The nitro-glycerine is absorbed by the soluble gun-cotton, and forms with it a substance somewhat like india-rubber.

Gelignite.—Nitro-glycerine 60 per cent., nitro-cotton 4 per cent., potassium nitrate 27 per cent., wood-pulp 9 per cent.

Monobel.—Nitro-glycerine 10 per cent., ammonium nitrate 80 per cent., charcoal 9 per cent., moisture 1 per cent.

Bellite.—Ammonium nitrate 85 per cent., di-nitro-benzene 15 per cent.

Faversham Powder No. 2.—Nitrate of ammonium 90 per cent., tri-nitro-toluene 9 per cent., moisture 1 per cent.

Roburite.—Ammonium nitrate 86 per cent., chloro-di-nitro-benzene ($\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)_2$) 14 per cent. This is di-nitro-benzene, with one atom of chlorine (Cl), replacing one atom of hydrogen.

Ammonite.—Ammonium nitrate 88 per cent., di-nitro-naphthalene 12 per cent.

Of the above, dynamite, blasting-gelatine, and gelignite are not ‘permitted’ explosives; the remainder are.

Mention has been made of picric acid as being used by itself for explosive purposes. This is specially the case for the filling of shell, for which purpose its property of becoming thoroughly liquid at 251°F . (122°C .) renders it very suitable, as in that condition it can be poured into the interior of the shell. For shell-filling tri-nitro-toluene is also well suited, as it melts at the lower temperature of 177°F . (81°C .), and has none of the objectionable chemical activity of picric acid leading to the formation of dangerous picrates. On the other hand, it is slightly less powerful, and needs a more powerful detonator to start detonation.

Compared with blasting-gunpowder, the cost of high explosives is much greater, their prices varying from about two to three times more than that of blasting-gunpowder; but on the other hand, according to their compositions, they are from two to three times as powerful (see GUN-COTTON).

See *Treatise on Service Explosives* (Official, 1907); *Manufacture of Explosives: Twenty Years' Progress*, by Guttman (London: Whittaker & Co., 1909); *Nitro Explosives*, by Sandford (London: Crosby, Lockwood, & Son, 1906); *Explosives*, by Marshall (London: J. & A. Churchill, 1917).

Dynamo-electric Machines are machines for generating electric currents by means of the relative movement of conductors and magnets. Faraday discovered in 1831 that an electric current is induced in a conductor when it is moved across the pole of a magnet, so that it cuts the lines of magnetic force, or (more generally) whenever the number of these lines which passes through the circuit of the conductor is in any way varied. If, for example, a coil of wire, the ends of which are connected so that the whole forms a closed circuit, be suddenly withdrawn from the pole of a magnet, a transient electric current is induced in it, while the lines of magnetic force which proceed from the pole are ceasing to be present within the coil. If the coil be replaced, a current will again be induced, but in the contrary direction. Similarly, a transient current is induced if the coil be held at rest while the magnet is drawn away; or, again, if the coil be turned round so that the direction of the lines of force through it becomes reversed, in which case the effect will be twice as great as before. Any movement which causes an alteration to take place in the amount of magnetic induction through the coil produces a transient current, the electromotive force of which is proportional to the rate at which this alteration takes place. The whole amount of electricity produced is the same whether the movement be fast or slow. When the movement is slow, the current lasts longer in proportion as its strength is less. To produce the movement requires an exertion of mechanical work, which finds its equivalent in the energy of the induced current.

Faraday's discovery was immediately followed by the invention of numerous forms of magneto-electric machines, as they were then called, in most of which a steel horseshoe magnet was made to

rotate over a pair of coils wound on a fixed armature, or the armature and coils were made to rotate while the magnet was held fixed. Fig. 1 is an example of one of these early forms, in which the

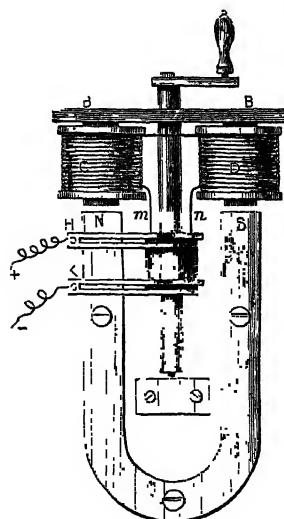

Fig. 1.

armature, BB, with the bobbins, C, D, which consist of coils wound upon iron cores fixed to the armature, revolves in front of the magnet poles, N, S. In every half-revolution the lines of magnetic force through the armature have their direction reversed, and a series of transient currents are consequently produced in the coils. These pass to the external part of the circuit through the spring brushes, H, K, which make contact with a revolving collector, consisting of insulated metallic rings on the axle, to which the ends, *m*, *n*, of the coils are attached. If *m* were always in contact with H, and *n* with K, it is obvious that each successive transient current would take the direction opposite to its predecessor—the direction of the current would alternate at every half-revolution. On the other hand, it is easy, by splitting the rings, to arrange the collector so that H is in contact with *m* for half a revolution, and then with *n* for the other half, while K is in contact first with *n*, and then with *m*, with the effect that the successive currents all have the same direction in the external portion of the circuit. The collector is then called a commutator. A simple form of commutator is shown in fig. 2.

Fig. 2.

An ideally simple form of dynamo is represented diagrammatically in fig. 3, which represents a conductor consisting of a single loop of wire revolving in the magnetic field between the poles of a magnet, NS, so that at every half-revolution the lines of force have their direction of passing through the loop reversed, and a series of transient currents is consequently induced in the loop. Here, again, a commutator is required if the currents are to have one continuous direction in the external portion of the circuit. In the position sketched (by full lines), the

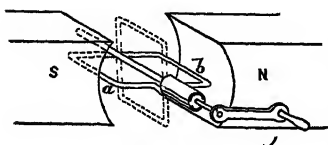

Fig. 3.

side, *a*, of the rectangular loop is cutting the lines of force in one direction, and the side, *b*, is cutting them in the other, and both these movements are contributing to produce electromotive force in one direction round the loop; the other two sides (i.e. the front and the back) of the loop do not cut lines of force, and therefore do not contribute to the production of electromotive force. As the loop approaches the vertical position (shown by dotted

lines), the component motion of the sides across the lines of magnetic force becomes reduced, and the electromotive force diminishes, till, at the vertical position, it disappears entirely, for there the sides of the loop are moving (at the instant) along the lines of force. After that they begin to cut the lines of force again, but in the reverse direction, and an electromotive force opposite to the last begins to act, which reaches its maximum when the coil is again horizontal. The same variations are repeated as the coil turns through the remaining half of its revolution. The strength of the current follows similar fluctuations, being determined by the electromotive force and by the resistance of the circuit, including the resistance of the revolving loop itself.

The effect of the revolving conductor in producing electromotive force may be increased (1) by increasing the speed of rotation; (2) by forming the loop with more than one turn of wire so as to make a coil, the whole effect is then the sum of the effects due to the individual turns; (3) by strengthening the magnetic field. One very important method of doing this is to furnish the revolving coil with an iron core, the effect of which is to increase the magnetic induction through the loop, across the space from pole to pole, by providing an easier path for the lines of magnetic force to cross this gap. In early dynamos the armature (as the revolving-piece is called) frequently consisted of a coil of many turns wound on an iron core, in the manner illustrated by fig. 4, which shows in section the simple shuttle-wound armature introduced by Siemens in 1856. The ends of the coil were brought to a commutator like that of fig. 2, and the effect was to produce currents which were uniform in direction. They were, however, very far from uniform in strength, varying from zero to a maximum twice in every revolution of the shaft.

Fig. 4.

In the early dynamos permanent steel magnets were used to produce the field in which the armature moved, but it was soon recognised that electro-magnets might be employed instead, and in 1863 Mr Wilde introduced a machine with large electro-magnets, which were excited by a small auxiliary armature revolving between the poles of a permanent magnet. Before this it had been proposed in machines with permanent magnets to supplement the magnetism when the machine was in action, by having coils wound upon the magnets, and by allowing the current produced in the machine itself to pass through these coils. It was not till 1867, however, that it became known that steel magnets were wholly unnecessary, and that dynamos with electro-magnets might be made entirely self-exciting. Even when the cores of the electro-magnets are of soft iron, there is enough residual magnetism to initiate a feeble current; this develops more magnetism, which in its turn develops more current, and so the process goes on until full magnetisation is reached. The principle of self-excitation was enunciated independently, and almost simultaneously, by Wheatstone, Werner Siemens, and S. A. Varley; it is now made use of in all except the smallest machines. The term 'dynamo-electric' was at first applied to distinguish those machines which were self-exciting from 'magneto-electric' machines, which had permanent magnets to give the field; but this distinction is no longer maintained, and the name 'dynamo' is now used in the wider sense defined above.

An extremely important step in the development of the dynamo was taken in 1870 by Gramme, who

introduced a form of armature which, for the first time, gave a current not merely continuous in direction, but also sensibly uniform in strength. The Gramme ring armature is shown diagrammatically in fig. 5. It consists of a ring-shaped

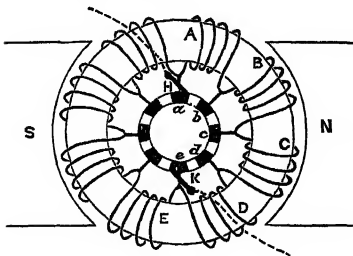

Fig. 5.

iron core, revolving in the magnetic field, and having a series of coils, A, B, C, &c., wound upon it. These are joined to one another in a continuous series, and also to the insulated segments of a commutator, *a, b, c*, which revolves with the ring, and from which the current is taken by brushes, H, K. Consider now the action of the field in producing electromotive force in any one of the coils, such as A. Near the place in which it is sketched, the coil A is moving in a direction parallel, or nearly parallel, to the lines of force, and, therefore, is having little or no electromotive force induced in it. But by the time the ring has made half a revolution, the same coil will have the lines of force within it reversed. Between these two positions, therefore, there must have been a generation of electromotive force, and this will in fact be going on most actively half-way between the two places. The coil C is at present the most active contributor of electromotive force, but B and D, the coils lying in front of and behind it, are also contributing a share, and the whole electromotive force between A and E, so far as that side of the ring is concerned, will be the sum of the several effects due to all the coils from A to E. A little consideration will show that the same action is going on on the other side of the ring, so that if the brushes be applied at *a* and *e* they will take off to the external portion of the circuit a current, half of which is contributed by one side, and half by the other side of the ring, the two sides acting like two groups of battery cells arranged in parallel and of equal resistance and equal electromotive force. The whole electromotive force in the armature is the same as that produced by the coils on one side alone, but the internal resistance is halved by the division of the current between the two sides. In actual Gramme armatures, the number of coils on the ring is very much greater than the number shown in the sketch, and each brush is made wide enough where it presses on the commutator to touch two of the segments at once. Hence the current is never interrupted, and the fluctuations in its strength, which occur as one segment passes out of contact and another comes in, may be made almost indefinitely small. As each coil passes, it is for the instant short-circuited through the brush, and this would give rise to a waste of energy in the coil and to sparking at the brushes, were it not that the brushes are set to bear on the commutator at the points where the development of electromotive force in the corresponding pair of coils is a minimum. These neutral points, as they are called, are not exactly midway between S and N, but are in advance of that position in consequence of the magnetic field within the ring being distorted through the action of the currents in the armature coils. Hence the brushes require to have what is called 'lead,' and this lead has in general to be adjusted whenever the output of the machine is considerably varied, more lead being needed if it happen that the arma-

ture current is increased while the field magnets remain of constant, or nearly constant, strength. As it often happens, especially in the case of a dynamo supplying power for traction purposes, that the demand for current is liable to severe fluctuations, it is obviously a great advantage to have a machine which will work sparklessly at all loads without the necessity of altering the adjustment of the brushes. Various expedients have been introduced with this end in view, chief among which are (1) carbon brushes, the high resistance of which checks the rush of current in the short-circuited coils; (2) small auxiliary poles, called 'interpoles,' midway between the main poles, excited by series coils, which supply a reversing field equivalent to giving lead to the brushes appropriate to every load; (3) compensating series windings, arranged to neutralise the distorting effect of the armature current.

A small practical Gramme dynamo of an early form is shown in fig. 6. In this example two field-

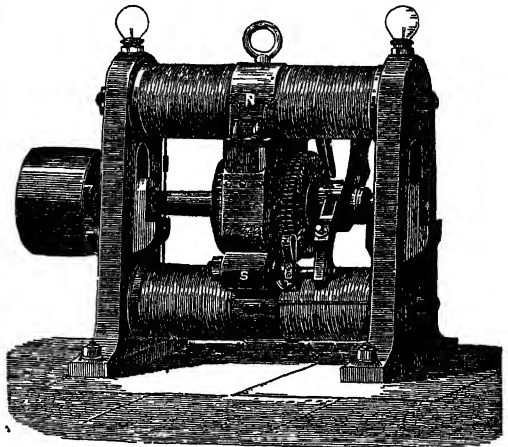

Fig. 6.

magnets conspire to produce a north pole at N, and two others to produce a south pole at S. The commutator is a series of copper bars mounted on an insulating hub fixed to the shaft, and separated from one another by thin strips of mica or other insulating material; these bars have radial projections, which are soldered to the junctions of successive armature coils. Each brush consists of a flat bundle of copper wires pressed lightly against

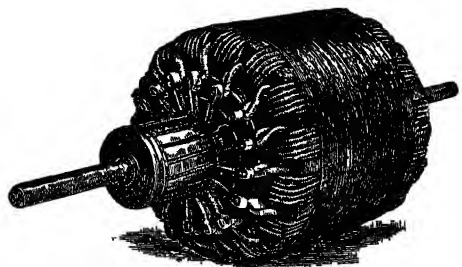

Fig. 7.

the commutator by a spring. The core of the armature is a ring made up of many turns of soft iron wire, on which insulated copper wire is wound to form the coils. It is essential that the core of the armature should not be solid, for in that case currents would be developed in the substance of

the moving iron itself to such an extent as very seriously to impair the efficiency of the machine. Hence the core of dynamo armatures is always subdivided, by being made up either of wire, or more usually of thin plates more or less carefully insulated from one another. Fig. 7 shows the armature of a small Gramme dynamo, removed from its place between the pole-pieces.

Two years after the introduction of the ring armature by Gramme, it was shown by Von Hefner Alteneck that the Siemens armature (fig. 4) might be modified so that it also should give continuous currents of practically constant strength. In the original Siemens armature there was but one coil, all wound parallel to one plane, and the current fluctuated from nothing to a maximum in every half-revolution. In the modified form the coil is divided into many parts, which are wound over the same core, but in a series of different planes, the plane of each successive coil being a little inclined to the plane of the coil before it. The coils are all joined in series, and their junctions are connected to the bars of a commutator just as in the Gramme ring. The Siemens-Alteneck or drum armature may, in fact, be compared to a Gramme armature, in which the coils, instead of being wound on successive portions of a ring, are all wound on one piece of core, preserving, however, the angular position they would have in the ring. Their action depends on their angular motion, and is therefore the same in both cases. As the drum revolves, that coil which is passing the neutral plane (viz. the plane perpendicular to the lines of force) is for the moment inoperative, and the brushes are set to touch those bars of the commutator that are connected with it. The other coils are more or less operative, the most active contributor of electromotive force being that one which is for the moment perpendicular to the neutral plane. The electrical effects in drum and in ring armatures are the same. Nearly all modern continuous current dynamos have drum armatures of the kind shown in fig. 8, mainly on account of the convenient

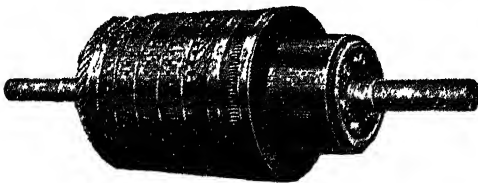

Fig. 8.

mechanical construction which can then be adopted. The core consists of a large number of discs of annealed sheet-steel with slots punched out at regular intervals round the periphery. At intervals of every two or three inches, air-ducts some half-inch wide are left between the plates through which the rotation causes air to circulate. These ducts are useless so far as the transmission of magnetic lines is concerned, but are invaluable for keeping the armature cool. The winding consists of a number of precisely similar coils of insulated copper wire, braid, or strip wound on a former, and then taped and varnished. Some idea of the peculiar shape of these coils will be gathered from fig. 9. They are inserted two-deep in each slot in such a way that each coil has one straight limb at the bottom of a slot, and the other straight limb at the top of a slot a certain number of slots in advance of the first slot. The coils are kept in place by wire bound round the periphery, or by wooden wedges driven into grooves at the tops of the slots, and the free ends of the coils are soldered to lugs attached to each commutator segment. The com-

mutator segments are of hard-drawn copper, and are insulated from each other by prepared mica of the same hardness as the copper, so that the surface under the brushes wears down evenly. The segments are held in place by V clamping-rings insulated with mica. The bolts for drawing these together can be seen spaced at intervals round the shaft.

An important element in the classification of dynamos is the manner in which magnetism is

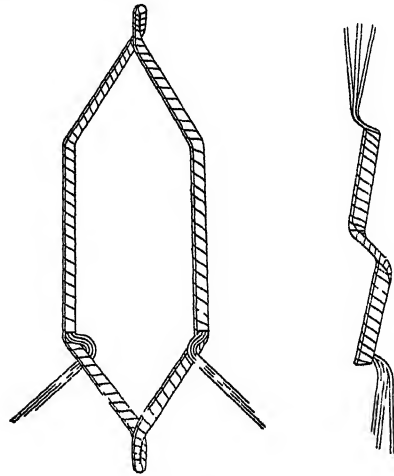

Fig. 9.

induced in the field-magnets. These may of course be excited from an independent source of electricity; but when the machine is self-exciting, there are three important alternative methods. In the early machines the coils on the field-magnets were connected in series with the external part of the circuit, and consequently the whole current produced by the machine passed through both. This arrangement is distinguished as *series winding*, and is shown diagrammatically in fig. 10. It was first pointed out by Wheatstone, in 1867, that the magnet coils, instead of being put in series with the external conductor, might be arranged as a

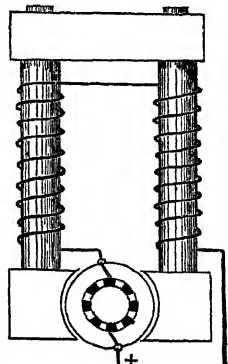

Fig. 10.

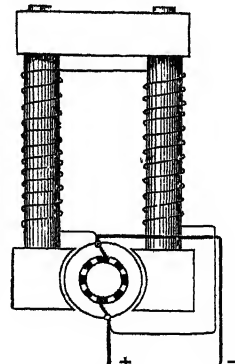

Fig. 11.

shunt to it, thereby forming an alternative path through which a portion only of the current would pass. In this arrangement, which is called *shunt winding* (fig. 11), the magnet coils consist of many turns of comparatively fine wire, so that they may not divert an excessive quantity of current from

the external circuit. Finally, in *compound winding* (fig. 12) the two previous methods are combined. The field-magnets are wound with two coils; one of these (which is short and thick) is connected in series with the external circuit, and the other (which is long and fine) is connected as a shunt to it. This plan appears to have been first used by Varley in 1876, and afterwards by Brush, who pointed out that it, along with simple shunt winding, has the advantage of maintaining the magnetic field even when the external circuit is interrupted. It has, however, when properly applied, another and more important merit, as will appear below.

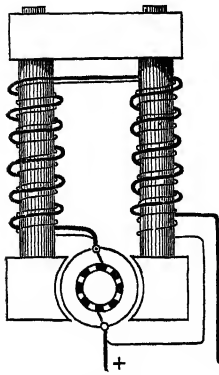

Fig. 12.

In a series-wound dynamo the magnets do not become excited if the external circuit is open, and become only feebly excited when the external resistance is high. Let the external resistance be reduced, while the armature is forced to turn at the same speed. The current will now increase, producing a stronger magnetic field; the electromotive force is therefore greater than before. A curve drawn to show the relation between the current and the difference of potential between the terminals of the machine (which is a little short of the full electromotive force, in consequence of the resistance of that part of the circuit which is within the machine

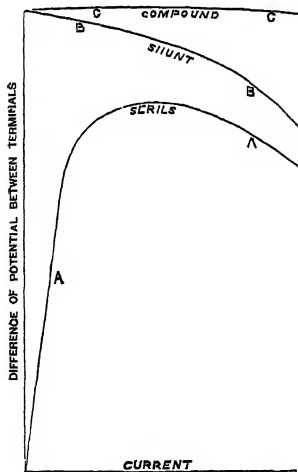

Fig. 13.

itself) will in its early portion rise fast as the current increases, in consequence of the rapid augmentation of the magnetic field. Such a curve is called the characteristic curve of the machine, and is shown at AA in fig. 13. If we continue to increase the current by further reducing the external resistance, the magnets tend to become saturated, and finally even have their magnetism somewhat weakened on account of the influence of the currents in the armature coils. Further, the loss of potential, through internal resistance, becomes more considerable. The difference of potential between the terminals accordingly passes a maximum, and becomes considerably reduced when the current is much augmented, as appears in fig. 13. The characteristic curve for a shunt-wound dynamo is shown at BB in the same figure. Here the strength of the magnetic field is nearly constant, but decreases a little when the machine is giving much current, partly because the current in the shunt circuit is then somewhat reduced, and partly because the current in the

armature coils tends to oppose the magnetisation. Hence the potential falls off as the current increases. This fall will, however, be slight if the resistance of the armature is very low and if the field-magnets are very strong, and under these conditions a shunt-wound dynamo will give a nearly constant difference of potential whether much or little current be taken from it, provided, of course, that the speed remain unchanged. To make the difference of potential more exactly constant, it is necessary that the magnetic field should become stronger when the machine is giving much current, and compound winding achieves this. A compound-wound dynamo may be regarded as a shunt machine in which the action of the shunt winding is supplemented by that of a series coil on the magnets. When the machine is running on open circuit, the shunt coil alone is operative; as the current taken from the machine is increased, the series coil produces a larger and larger supplementary effect on the magnets, and by choosing a proper number of series windings, their effect may be made to neutralise with great exactness the droop in the characteristic curve which would occur if the shunt coil were the only source of magnetism. Compound machines wound for constant potential give a nearly straight horizontal line for their characteristic; CC in fig. 13 is an actual example. By making the series coil more influential, so that the potential at the terminals rises slightly as the current increases, the machine may be compound-wound to give constant potential at the ends of long leading-wires by which the current is conducted to a distance.

Series-wound dynamos were at one time largely employed for electric lighting by arc lamps. Shunt machines are the most suitable for charging storage batteries and for electro-plating.

Fig. 14 illustrates the front and rear of a Westinghouse generator (with shaft removed) for coupling

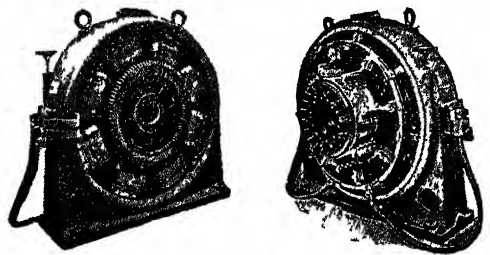

Fig. 14.

direct to a reciprocating engine, which gives a good idea of the modern way of constructing such machines. The rear view shows that the magnetic circuit consists of eight poles projecting inwards from a circular yoke. The series winding, consisting of a few turns of flat copper strip wound on edge, is seen enveloping the poles next to the yoke. The large rectangular coils at the tips of the poles, consisting of a large number of turns of comparatively fine wire, constitute the shunt winding. Turning to the front view, we notice a ring carrying the eight brush-arms, which may be rocked through a small angle by means of the hand-wheel provided for the purpose. The brushes consist of rectangular blocks of carbon set normal to the surface of the commutator, and kept lightly pressing upon it by springs, the strength of which can be adjusted. Just as the polarity of the magnets is alternately north and south, so the polarity of the brush-arms is alternately positive and negative. Cross connections are provided which join up electrically each group of brushes of the same polarity, and flexible leads bring the current from each group to a terminal block fixed

at the side of the machine. It will be noticed that the armature spider on which the laminations are carried is hollowed out so that air may freely enter, to be afterwards whirled through the air-ducts in the armature core, of which mention has already been made.

The rise of the steam-turbine to its present important position as a prime mover has exercised a profound influence on dynamo construction, and has necessitated the development of a distinct class of electric generator to suit the very high speed of rotation. Two difficulties have to be overcome: (1) to make the armature and commutator strong enough to resist the enormous centrifugal forces to which these are subjected; (2) to prevent sparking at the commutator due to the very rapid rate at which the current has to be reversed in the armature coils, and the large difference of potential existing between adjacent commutator segments.

In recent years, due to the expansion that has taken place in the area over which central stations distribute electricity, the *alternating current dynamo* or 'alternator' has more and more taken the place of the direct current dynamo for converting the mechanical energy of the prime mover into electrical energy. This is because there is difficulty in getting any machine with a commutator to work satisfactorily when the potential difference between the brushes exceeds, say, 1000 volts, and because with alternating currents the

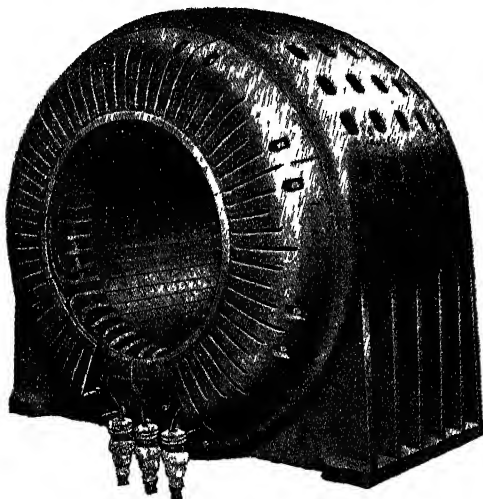

Fig. 15.

static transformer (see article on Electric Light) affords such an easy and efficient means of raising or lowering the pressure.

In early forms of alternating dynamo the armature usually consisted of a group of coils, joined in parallel or series, attached to a disc which revolves in the space between a corresponding group of pairs of magnet poles, so that rapidly alternating transient currents are induced as the coils pass the successive poles, and these currents pass to the external circuit through a simple collector which is not a commutator.

Figs. 15 and 16 show the stator and rotor of a three-phase alternator, designed for coupling direct to a steam-turbine. It will be seen that in this case, as is now usual in large machines, the armature is situated outside and is fixed, and a high pressure is induced in the windings by four field-magnet poles, which rotate within them at a speed of some 1500 revolutions per minute. The current

for exciting the magnets is here obtained from a small low-tension continuous current dynamo fixed at the far end of the shaft, and is led into the field-winding by means of a couple of collector rings

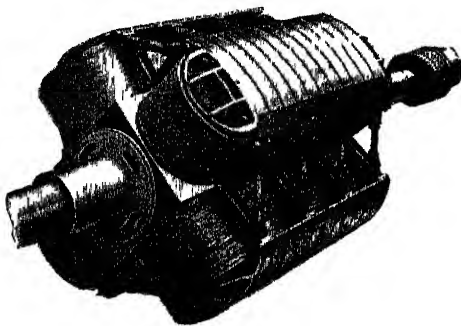

Fig. 16.

(not shown in fig. 16). Interesting mechanical features of the rotor are the very massive end-brackets and diagonal struts necessary to prevent the field-winding bulging under the high centrifugal forces to which it is subjected. The elaborate provision made for ventilating both stator and rotor should also be noticed. The so-called salient pole construction of fig. 16 is now largely confined to rotors of 6 poles or more driven by water turbines. When the prime mover is a steam turbine it is important in the interests of economy of steam to employ the highest possible speed. Now the field system cannot have less than 2 poles, which for a standard frequency of 50 cycles per second means a speed of 3000 r.p.m. This plan is found practicable up to outputs of 20,000 k.v.a. For still larger units recourse is had to a 4-pole design turning at 1500 r.p.m. In these large high-speed turbo-alternators the revolving field is of the non-salient or cylindrical type—i.e. the magnetising coils are embedded in slots somewhat after the fashion of a d.c. armature, except that the slots are grouped between the pole centres instead of being evenly spaced all round the circumference. In alternate current dynamos, the relation between the strength of the current and electromotive force induced in the moving coils depends not merely on the resistance of the circuit, but also on its coefficient of self-induction, which has the effect of making the maximum of strength in each transient current lag behind the maximum of electromotive force. It was shown experimentally and theoretically, by Adams and Hopkinson, that in consequence of self-induction two similar alternate current machines driven independently, but started at the same speed, and connected in parallel, will control one another, so that the phases of the currents will continue to agree, and in alternating current generating stations it is usual to find several machines running in parallel in this way.

Dynamos, of whatever type, may be regarded as machines for converting energy from a mechanical into an electrical form, and from this point of view a matter of prime importance is what is called the efficiency of the machine, which is the ratio of the electrical power the dynamo gives off, available for use outside the machine, to the power used to drive the machine. The electrical energy given off falls short of the mechanical energy absorbed, in consequence of (1) mechanical friction; (2) the generation of eddy currents, to be prevented as much as possible by laminating the iron core of the armature; (3) magnetic friction or 'hysteresis,' by which every reversal of magnetism in the iron causes dissipation of energy, apart from the production

of eddy currents; (4) the energy consumed in maintaining the magnetic field; and (5) the heating of the armature in consequence of the resistance of its own coils. The aggregate effect of these sources of loss is that some 85 to 95 per cent. of the driving-power (according to the size of the machine) is available as electric energy in the external circuit. The efficiency of high-pressure turbo-alternators is remarkably high, often exceeding 97 per cent. in the larger sizes.

The Dynamo as a Motor.—Just as a conductor when made to move across the lines of magnetic force has a current generated in it, so when a current is made to pass along a conductor placed in a magnetic field, the conductor tends to move across the field in the direction which would reduce the current by inducing an opposing electromotive force. Even before Faraday's discovery of the induction of current in a conductor by its movement in a magnetic field, he had shown (in 1821) that the reverse process was possible, and soon afterwards various forms of magneto-electric engines were devised by Barlow and Sturgeon, and later by Ritchie, Henry, Dal Negro, Joule, and others, which employed electric currents to do mechanical work on a small scale. In 1833 Jacobi constructed an electric motor of sufficient power to propel a small boat, using a group of electro-magnets, which revolved on a disc between opposite groups of other electro-magnets, which were fixed. Some time before the application of the ring-armature to dynamos by Gramme, it had been used in a motor by Pacinotti, and the principle had been explicitly stated that any electric motor might be used to produce currents, but it was not until Gramme's time that the full significance of this principle was generally recognised. The action of the dynamo is in fact reversible; the same machine which converts mechanical into electrical energy will serve the opposite function equally well. Power may therefore be conveyed to any distance by using a dynamo to produce currents, conducting these to the distant spot, and utilising them there to produce mechanical effect by means of another dynamo acting as a motor.

Just as there are series, shunt, and compound wound dynamos, so there are series, shunt, and compound wound motors, each of which possesses its own sphere of usefulness. With a constant electromotive force applied at the terminals, a shunt-wound motor tends to rotate at a nearly constant speed at all loads, which makes it suitable for driving machine tools, textile machinery, and the like, where a constant speed of rotation is required. In series and compound wound motors, on the other hand, the speed under similar circumstances falls off when the load increases, which fact renders them suitable for traction purposes, cranes, &c., where it is advantageous that a heavy load should be overcome at a reduced speed. The powerful torque which these last-mentioned motors exert at starting also renders them specially valuable for all classes of work in which the motor has to be frequently started with the load on.

The factors controlling the current passing through the winding of a motor are (1) the impressed electromotive force, (2) the resistance of the winding, (3) the opposing or so-called 'back electromotive force' induced in the conductors in virtue of the rate at which they are cutting magnetic lines of force. When the armature is at rest item (3) is zero, and consequently an abnormally large current tends to flow when the current is first switched on. To prevent this rush of current at starting, an external resistance has to be introduced, which is cut out slowly as the speed (and consequently the back electromotive force) rises.

Alternate current dynamos form fairly efficient

motors when driven by alternate currents; they require to be started in synchronism with the impulses received from the generating machine, but once started they tend to remain in synchronism.

The motor which is most extensively used with polyphase currents, however, is of a totally different type, called the *induction motor*. Its development dates from the discovery of the possibility of producing rotating waves of magnetic flux by means of polyphase currents, made by Ferraris (1885) and by Tesla (1888), in such a manner that a continuous

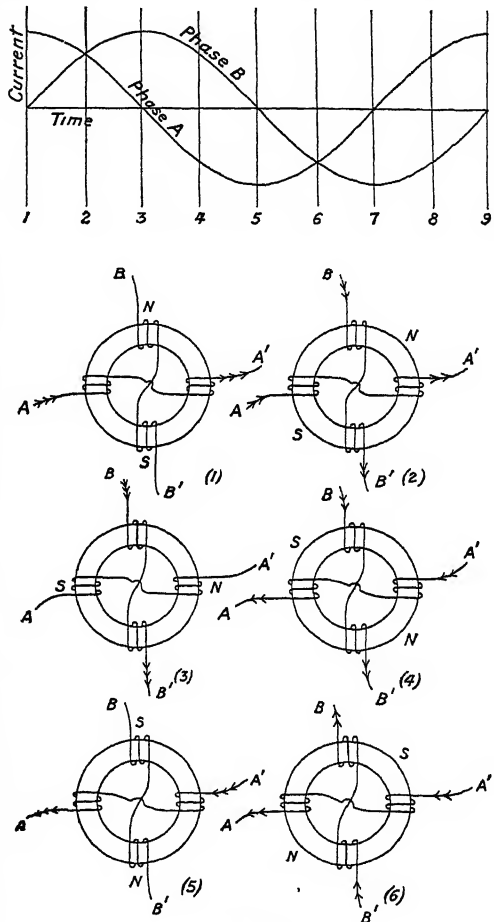

Fig. 17.

turning effect is produced between a stationary winding, called the stator, and a rotating member, called the rotor.

An elementary conception of the so-called 'rotating field' produced can be obtained by tracing step by step the magnetic field induced in a soft iron ring (fig. 17), when two coils (AA' and BB'), whose axes are at right angles, are traversed by alternating currents differing by a right angle in phase. The two sine curves at the top of the same figure, marked phase A and phase B respectively, have been drawn to represent these two currents throughout a complete cycle. At the instant which we will designate (1) the current in phase A has its maximum positive value, flowing in the direction indicated by the arrow-heads. The induced magnetic field will be such that a north pole is produced at the top and a south pole at the bottom, as indicated by the letters N and S. The current

in phase B, being zero at the moment, is without magnetic effect. At the instant (3) the current in phase A has vanished, but now the current in phase B has risen to its maximum positive value, and consequently the new axis of magnetism is horizontal with poles as indicated by the letters N and S. Returning now to the intermediate instant (2), a reduced current is seen to be flowing in at A and out at A' as at instant (1), simultaneously with a reduced current flowing in at B and out at B' as at instant (3). The resultant magnetic effect is evidently to induce north and south poles at positions intermediate between corresponding positions of these poles at instants (1) and (3). Enough has now been said to make it clear that the magnetism travels round gradually

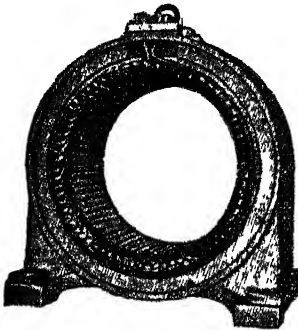

Fig. 18.

through a quadrant between the instants (1) and (3); and, as indicated in the figure, it travels through another quadrant in the time taken for either phase of the supply current to make a complete period. A precisely similar effect is obtainable when the

iron ring carries three coils traversed by three-phase currents. In actual induction motors the soft iron ring is replaced by an assemblage of annular punchings mounted in a hollow cylindrical frame (see fig. 18). The winding is situated in slots punched at regular intervals round the internal periphery of the laminations. The rotor (fig. 19) consists in this case of a core built up of sheet-steel punchings, and threaded all round the periphery by a number of stout copper bars riveted back and front to heavy end rings of copper or brass. From the resemblance of the construction, this type of rotor is called a 'squirrel cage.'

When current is first switched on to the stator winding, large currents are induced in the bars of

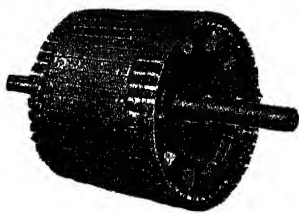

Fig. 19.

the rotor in the same way as currents are induced in the secondary winding of a transformer (see ELECTRIC LIGHTING) by the passage of an alternating current in the primary. The electro-magnetic effect between the current in the copper bars of the rotor and the rotating field of the stator causes the rotor to revolve in the same direction as the field until a speed is attained only slightly less than that of the rotating field itself. An attractive feature of this type of motor is the absence of commutator, brushes, and all rubbing contacts. As regards efficiency, there is practically no difference between that of an induction motor and of a continuous current motor of the same output. A disadvantage of the squirrel-cage type is that if the rotor is designed to have a good efficiency at full load, a large current is taken at starting, and, in spite of this, the turning moment or 'torque' produced may be insufficient to start the motor.

In such cases it is necessary to make the motor drive through some form of clutch by means of which the rotor is enabled to attain full speed before the load is thrown on. A satisfactory method of controlling the speed is also difficult to secure.

A good starting torque and an easy means of controlling the speed can be obtained by employing a 'wound' rotor with slip rings, but this means introducing rubbing contacts, and the performance at reduced speeds is uneconomical.

Induction motors can also be made which will operate on single-phase circuits, but in this case the magnetic field does not rotate, but only pulsates, so that it requires some special device to make the motor self-starting. In fact, the turning effect in a single-phase, two-phase, and three-phase induction motor is analogous to the turning moment experienced by the shaft of an engine operated by a single crank, two cranks at right angles, and three cranks at 120° respectively.

Returning for a moment to the consideration of the continuous-current series motor, a little consideration will suffice to show that this motor may also be operated by a single-phase alternating current, for at each reversal the direction of the current is changed both in the armature and the field, and consequently the turning moment experienced by the armature is always in the same direction. Working on these lines, the Westinghouse Company have produced a single-phase series motor which has been successfully applied for traction purposes; and the Oerlikon Company and Messrs Siemens have also brought out series motors with commutating poles.

Another type of motor for single-phase alternating current, also using a commutator, is the 'repulsion motor' originally invented by Professor Elihu Thomson in 1887. An improved compensated motor of this type has been adopted by the Southern Railway for propelling the trains on the electrified sections of their system (see ELECTRIC RAILWAY).

See ELECTRIC LIGHT, ELECTRIC RAILWAY, TRAMWAYS; and for the utilisation of water-power, ALUMINIUM, FOYERS, NIAGARA. On the theory of dynamos, see papers by J. Hopkinson (*Proc. Inst. Mech. Eng.* 1879-80), in which were explained the construction and uses of curves, such as those of fig. 13 (afterwards called characteristic curves by Deprez); by J. and E. Hopkinson (*Phil. Trans.* 1886), in which it was shown how the strength of the field and the performance generally of a dynamo might be predicted by calculation of the induction in the magnetic circuit of the machine. See articles in *Proc. Inst. Elect. Eng.*, *The Electrician*, &c.; C. C. Hawkins, *Dynamo Electric Machinery*; H. M. Hobart, *Electric Motors*; Miles Walker, *Specification and Design of Dynamo Electric Machinery*; E. Hausman, *Dynamo Electric Machinery*; A. T. Dover, *Electric Motors and Control Systems*; W. J. MacCall, *Continuous Current Electrical Engineering*; also *Alternating Current Electrical Engineering* by the same author; J. F. C. Snell, *Power House Design*.

Dynamometer, originally an instrument for measuring force, such as the pull exerted by a horse in drawing a cart; but the name is now usually given to instruments for measuring power. A friction brake, for example, applied to a drum on the shaft of a steam-engine, may be arranged so that it measures the rate at which the engine is doing work on the brake: the device then forms an *absorption dynamometer*. There are also various *transmission dynamometers* which measure the power conveyed by a belt or by a shaft without absorbing it.

Dyne. See FORCE.

Dyothetism. See CHRIST.

Dyrrhachium. See DURAZZO.

Dysart, an old-fashioned seaport of Fife, on the Firth of Forth, 2½ miles N.E. of Kirkcaldy. It owes

its name (Lat. *desertum*, 'a solitude') to St Serf's cave near Dysart House, Lord Rosslyn's seat; was a thriving place prior to the Union; and now has some textile manufactures and collieries. James V. made it a royal burgh, and with Kirkcaldy, Burntisland, Kinghorn, and Buckhaven, Methil, and Innerleven, it returns one member to parliament. Pop. of royal burgh (1851) 1610; (1891) 3022; (1921) 4598.

Dyscrasia (Gr. *dys*-, 'difficult,' and *krasis*, 'a mixture'), a pathological term much used by some authorities to indicate an altered condition of the blood and fluids of the system, leading to constitutional diseases, as dropsy, cancer, delirium tremens, &c. See CACHEXIA and DIATHESIS.

Dysentery (Gr. *dys*-, 'difficult,' and *enteron*, 'the intestine') is the name applied to disease characterised by pain in the abdomen, frequent and painful efforts to evacuate the contents of the lower bowel, resulting in the passage of small but usually bloody and slimy stools, and produced by severe inflammation of the large intestine. Till a few years ago, it was believed to be one definite disease; it is now known that the conditions above described may be produced by many different causes, so that under one name numerous distinct diseases are included. Far the most important of these are *bacillary* and *amoebic* dysentery, produced by the presence in the intestines of a bacillus and an amoeba respectively.

Dysenteric diseases are much more prevalent in tropical than in temperate countries, but are apt to appear even in the latter under bad hygienic conditions (bad drainage and water-supply, overcrowding, unsatisfactory feeding, &c.), and therefore especially in time of war.

Dysentery may begin suddenly and severely, sometimes with a rapidly fatal issue, or gradually and insidiously; it may be readily curable, or it may become chronic and persist for years; it may occur in isolated cases, usually of a mild type, or may give rise to extensive and fatal epidemics. The most important complication is abscess of the liver, which is frequent in amoebic dysentery, and very rarely met with in Great Britain, except in those who have contracted it in the tropics. At the commencement of an attack the patient should be kept in bed on a light and very sparing diet, and a dose of castor oil and laudanum should be administered. Further treatment ought to be determined by the causation of the disease; but this cannot always be made out, even on microscopic examination of the stools. In amoebic dysentery, ipecacuan, or its active principle, emetine, is far the most effective drug; in bacillary dysentery the sulphates of sodium and magnesium in repeated doses are most useful. It is important, therefore, that medical supervision should be obtained, whenever possible, at the onset of the disease; and hardly less important that it should be continued till the case is cured, as recurrences and complications frequently occur.

Dysodil, a yellow or grayish laminated bituminous mineral, often found with lignite. It burns vividly, and diffuses an odour of asafetida.

Dyspepsia. See INDIGESTION.

Dysphonia. See THROAT (AFFECTIONS OF THE).

Dyspnoea. See ASTHMA, RESPIRATION.

Dysuria (Gr. *dys*-, 'difficult,' and *ouron*, 'urine'), a difficulty of passing urine, may depend on a variety of causes. See URINE.

Dytiscus, or DYTICUS (Gr. *dytēs*, 'a diver'), a genus of water-beetles, including the large British species, *D. marginalis*. See WATER-BEETLE.

Dyveke ('the little dove'), called by the Latin chroniclers *Columbula*, the famous mistress of Christian II. of Denmark. Born at Amsterdam in 1488, she was but nineteen when she first met her lover at Bergen, where her mother had settled as an innkeeper. She followed him to Denmark, where her mother acquired such political influence as to become hated by the nobles. Dyveke, who herself took no interest in affairs, died suddenly in 1517, almost certainly from poison. Christian avenged his favourite's death by executing a young noble, Torben Oxe, whom he suspected at least of having himself aspired to her favour. The unhappy fate of Dyveke has been the subject of dramas in Danish or in German by Samsøe (1796), H. Marggraff (1839), and Rièkhoff (1843); and of romances by L. Schlefer, Tromlitz, Carsten Hauch, and Ida Frick. See Munch's *Biographisch-historische Studien* (1836).

Dyvoor, in the old legal language of Scotland, was a bankrupt who under various acts from 1606 to 1696 was until discharged compelled to wear a hideous and conspicuous costume. Thus an act of 1688 prescribes as the dyvoor's habit 'a bonnet, partly of a brown and partly of a yellow colour, with uppermost hose, or stockings, on his legs, half brown and half yellow coloured, conform to a pattern delivered to the magistrates of Edinburgh.' The barbarous usage had fallen into desuetude long ere the dyvoor's habit was abolished by law in 1836.

Dziggetai (*Equus hemionus*), a species of wild ass, more horse-like than the others. It is probably the hemionus ('half-ass') of Herodotus and Pliny. It inhabits the elevated steppes of Tatar, extending into the south of Siberia and to the borders of India. The Dziggetai lives in small herds, sometimes of several males and several females, sometimes of a single male with about twenty females and foals. The Mongols and Tungús hunt it eagerly on account of its flesh, but its fleetness, watchfulness, and power of endurance often secure its safety. It has been partly domesticated, but does not seem to breed in captivity. It is also known by the names of Kiang, Khur, and Goor. See ASS.

Dzungaria. See ZUNGARIA.

E

the fifth letter of our alphabet, descends from the fifth letter of the ancient Semitic alphabet, which expressed the sound of our *h*. Its form in the 9th century

B.C. was *𐤅*, afterwards *𐤆* ;

in the Aramaic type of Semitic writing it was turned on its side,

and developed into the Syriac *ܐ*, *ܐ*, and the

Hebrew *ה*. The Semitic name of the letter, *hē*

(preserved in Hebrew and Syriac), appears to have no meaning, but to have been arbitrarily invented to denote the sound. Some scholars have conjectured that the character was a modification of

the eighth letter, *𐤈* (see H), which expressed a

cognate sound; but this is very doubtful. The Greeks adopted the letter in the form *Ε*, which when the direction of the writing was reversed became *Ε*. (Some other forms occur in early inscriptions, but the original type ultimately prevailed.) Although the Greeks had the sound *h* in their language, they apprehended it rather as an affection of the vowel than as a separable consonant; hence the name *hē* naturally suggested the use of *Ε* as the needed sign for the mid-front vowel. In most parts of Greece it stood for the narrow variety of this vowel (=French *é* in *été*). This sound was normally short; when by exception it was pronounced long, it was in the 4th century B.C. written *ΕΙ*. Hence, according to ancient testimony, the alphabetic name of *Ε* in classical Greek was *εἴ*. Its name in late Greek, *epsilon*, literally 'bare' or 'simple' *e*, was (according to the now prevailing view) intended to distinguish the letter from the digraph *αι*, which had come to have the same sound. In modern Greek the letter when accented is sounded as *e* in *there*, when unaccented as *e* in *then*.

The Romans adopted the usual Greek form *E*, which is general in inscriptions, though *II* (the origin of which is obscure) is occasionally found. In writing on parchment, the nature of the material favours the development of the rounded form *Ε*,

whence (through the intermediate form *Ε*) our modern printed *e* is derived, as well as the many widely divergent forms found in mediæval manuscripts. The various forms now in use, script and printed, are of obvious origin, except the small German written *ſ*, which represents an older *ε*, the middle stroke being adapted for junction with the following letter.

In Latin, *E* expressed a vowel sound differing from that of *I* (=English *i* in *machine*, *pin*) in being produced with a lower position of the tongue. This description, which includes many varieties of articulation, represents the normal value of the letter in all modern languages except English, where the ordinary long sound of *E* (used as its alphabetic name) is now identical with the Continental sound of *I*. The ordinary English short *E* (as in *bed*) and the long *E* in *there*, &c., retain the original sound.

Italian and French grammarians have long applied the terms 'close' and 'open' to different varieties of the vowel; in French, when the quality is not indicated by position, the close *E* is written *é*, and the open *E*, *ê*, or *è*; in Italian the distinction is not shown in writing. In Middle English the vowel represented by *E* had, when long, two distinct qualities; Chaucer never rhymes a word like *meten*, to meet (close *E*), with one like *eten*, to eat (open *E*). In French and English (and in German, Dutch, and the Scandinavian languages) *E*, in addition to its original use, was early employed to denote the obscure vowel derived from various unaccented vowels in the older language. In English during the 14th century this vowel came to be dropped in pronunciation at the end of words, but the spelling remained unaltered. A mute *E* thus became part of English orthography, and until the 17th century it was often added arbitrarily at the end of words. In modern spelling it is retained chiefly when it serves a phonetic purpose, as to mark a preceding vowel as long (compare *mane*, *man*), or to indicate the 'soft' sound of *C* and *G*. An unfortunate exception exists in such phonetically misleading spellings as *give*, *have*, which have been retained owing to reluctance to use *V* as a final. Other exceptions, of various origin, are seen in *one*, *done*, *come*, *exquisite*, &c. Modern French has a mute *E* of similar origin, but it is still pronounced in singing, and is counted in the scansion of verse. In English, as in some other languages, *E* forms part of vowel digraphs, as *ea*, *ei*, *eo*, *eu*, *ew*, *ey*, *ae*, *ie*, *oe*, which express simple sounds, and have mostly more than one phonetic value.

For *E*, the third note of the natural diatonic scale, see MUSIC, SCALE, KEY; and for *e*, the radix of Napierian logarithms, see LOGARITHMS.

Eadgar, Eadmund. See EDGAR, EDMUND.

Eadie, JOHN (1810-76), United Presbyterian minister and lecturer on exegesis in Glasgow, born at Alva, wrote encyclopædias and commentaries. See Life by J. Brown (1878).

Eadmer, a learned monk of Canterbury about the end of the 11th century, the devoted friend of Archbishop Anselm, to whom he had been sent by Pope Urban. There also he remained in the same favour with St Anselm's successor, Archbishop Ralph, until 1120, when at the request of King Alexander I. he went to Scotland to become Bishop of St Andrews. There was already a controversy between Canterbury and York for jurisdiction over the see of St Andrews; while that see asserted its independence of either. Eadmer claimed to be consecrated by the Archbishop of Canterbury, but the Scottish king naturally refused to recognise this right, and accordingly the monk returned to Canterbury, whence eighteen months later he sent his renunciation of all claims to the bishopric. He died, it is supposed, in 1124. He tells us that from his childhood he was a diligent observer of contemporary events, especially in church affairs; and this habit has given more than usual interest to his writings, which show no little literary dexterity in their clearness and selection merely of such historical details as are really significant. The most valuable are his *Historia Novorum*, first printed by Selden in 1623, and his *Vita Anselmi*, first pub-

lished at Antwerp in 1551. Both were edited (1884) in the 'Rolls' series by Martin Rule. His lives of St Dunstan, and St Biegwin of Canterbury, and of St Oswald of York, were painted by Wharton in the second part of his *Anglia Sacra* (1691).

Eagle, a name given to many birds of prey in the order Accipitres, family Falconidæ, and sub-family Aquilinæ. The Golden Eagle, the White-tailed Eagle, and the Bald-Eagle are characteristic examples. Eagles, which are nearly related to buzzards and vultures, are thoroughly carnivorous birds, of cosmopolitan distribution. They hunt by day, and usually rest and nest in more or less inaccessible rocky places. The strong bill is not toothed as in the falcons; the bony shield over the eye is prominent; the legs and feet are heavy; the claws are long, curved, and very strong; the soles of the toes bear large callosities.

(1) The genus *Aquila* includes the Golden Eagle, the Imperial Eagle, and other species. The bill is large and high, with the upper part much bent, and with notched margins; the powerful wings reach to the end of the tail, and are rounded off; the tail is of medium size, broad, and straight; the leg-feathers extend down to the toes. Representatives of this noble genus are found in all parts of the world except the neotropical and Australian regions. The powers of vision and flight are well known; the power of 'renewing youth' is mythical.

The Golden Eagle (*A. chrysaetus*) is a large and magnificent bird. The predominant colour is dark, tawny brown, but the back of the head and neck are more tawny and look golden in the sunlight. The young birds have tails of a brighter colour. The adult female measures about 3 feet in length; the male is rather less both in length of body and

is loud and shrill, but with some hoarseness. The golden eagle has increased considerably in the north of Scotland since the protection of deer-forests has secured the necessary wildness, and since an appreciation of its nobility has increased among land-owners and sportsmen. The species is widely distributed in Europe, Asia, and North America. Allied species are the Imperial Eagle (*A. imperialis*) in south-eastern Europe, western Asia, and North Africa; and the Screaming Eagle (*A. nevia*), with similar distribution, but commoner in the north of Europe than either of the above species.

(2) *Other Genera*.—The Crested Eagles (*Spizaetus* and *Morphnus*), the former in tropical parts of both hemispheres, the latter in South and Central America, are in some species distinguished by tufts of feathers on the back of the head. The Harrier-eagles (*Circæus*) of Europe, North Africa, and western Asia are usually included with the hawks. The European species (*C. gallicus*) is known as Jean-le-Blanc. The White-tailed or Sea Eagles (*Haliaetus*) are absent only in South America. One species (*H. vibicilla*) is, like the golden eagle, a British species, becoming as usual increasingly rare (see ERNE). Its analogue in America is the Bald-eagle (*H. leucocephalus*), which extends from the north to California and Mexico. The Fishing Eagle, Osprey (q.v.), or Fish-hawk (*Pandion haliaetus*) is an almost cosmopolitan bird, requiring a family (Pandionidæ) for itself. It nests on high trees, and is remarkable for the backward grasping adaptation of the outermost toe. The Harpy-eagle of South America (*Thrasaetus harpyia*) is extremely fierce and strong, but does not take the initiative in attacking man. There are several eagles in Australia, such as the black *Uroaetus* *australis*.

While undoubtedly doing much damage to useful birds and quadrupeds, the eagles must be allowed some share in the credit of keeping down 'vermin.' In one case at least, the prey consists in part of serpents. Eagles seem to be long-lived birds, but precise information is far to seek; there is good evidence of a Sea-eagle attaining to four-score years, and Brehm speaks of a Golden Eagle that was more than a centenarian.

In Mythology, the eagle usually represents the sun; its beak, its talons, or the whole bird itself, the lightning and the sunbeam. The great mythical eagle of India, the Garuda, is the bearer of the god Vishnu, victorious by his brightness over all demons. In the Scandinavian mythology, the eagle is a gloomy figure assumed by demons of darkness, or by Odin himself, concealed in gloomy night or in wind-swept cloud. The storm-giant Hræsvelgr sits in the form of an eagle at the extremity of heaven, and blows blasts of wind over all peoples; and on the great tree Yggdrasil sits an eagle observing everything that happens. When Zeus was preparing for his struggle with the Titans, the eagle brought him a thunderbolt, whereupon the god took the bird for his emblem. He holds the bolts of Zeus in his talons, inspires heroes with courage, and also carries out the tyrannous behests of Zeus, as in tearing at the heart of Prometheus, and carrying off Ganymede from the earth. As an emblem of the immortal gods he becomes also a symbol of abstract immortality and of the human soul ascending after death. From the analogy of the heavenly authority of Zeus, the eagle also became the symbol of earthly power. Ptolemy Soter made it the emblem of the Egyptian kingdom. In the Roman story, an eagle was the herald to Tarquinius of his royal power, and it was one of the most important insignia of the republic, was also assumed by the emperors, and adopted into medieval heraldry after the time of Charlemagne. In the apotheosis of the Roman emperors,

The Golden Eagle (*Aquila chrysaetus*), Adult Male.
From E. T. Booth's *Birds of the British Islands* (Porter, London, 1881).

wing. The golden eagles have their homes in remote rocky regions, but often wander far in search of booty. They prey upon numerous mammals and birds, but are rarely willing to run any great risks in so doing. Rabbits, hares, lambs, and even young deer; ducks, plovers, ptarmigan, and the like, are seized and torn up, or carried home to the eyry. They have been known to drive roe deer over the rocks, and even to attack a pony, but at the same time they do not disdain carrion. The nest, usually upon a rocky ledge, is large and roughly made. There are most commonly two eggs. Though a strong and majestic bird, it cannot be credited with much bravery. The occasional cry

an eagle ascending from a funeral pyre symbolised their reception among the gods. Even in Christian symbolism the eagle has preserved to the present day its significance as the symbol of St John the Evangelist in the lecterns of churches.

As a standard of war the eagle seems first to have been used by the Persians, but the most famous eagles of antiquity were those that so often carried the Romans on to victory. These were made of silver or bronze and with outstretched wings, and were carried before the legions upon long poles, just as the great Napoleon's armies after 1804 carried gilded eagles with outstretched wings in place of banners.

The German imperial eagle was originally one-headed, and was first adopted by Charlemagne as a symbol of his empire after his coronation at Rome in 800. We find it already on the imperial banner in the time of the Emperor Otto II. When it came to be armorially depicted, its blazon was or, an eagle displayed sable, beaked and membered gules. The eagle is occasionally figured as two-headed towards the end of the 13th century, and is so represented on coins of Ludwig the Bavarian in 1325. Two headed eagles are found in Sumerian and Hittite symbols. The eagle of the Holy Roman Empire was first crowned in the 15th century; somewhat later the sword, sceptre, and orb came to be borne in its claws; and on the breast of the eagle were the personal arms of the emperor. In the arms of the later German empire (fig. 1) an eagle (with one head) displayed sable, beaked and membered gules, sustained on its breast a shield containing the arms of Prussia—viz. argent, an eagle displayed sable, crowned, armed, and membered or, and charged on the breast with the arms of Hohenzollern—viz. quarterly argent and sable, with which was entwined the collar of the order of the Black Eagle. On the

Fig. 1.—German Empire.

Fig. 2.—Austrian Empire.

head of the imperial eagle rested the imperial crown, from which fell down on both sides golden fillets embellished with arabesques. The republic dropped the crown and the shield with its arms, and closed the plumage. The Prussian eagle is the original imperial eagle granted as a special mark of honour to the Teutonic knights by the Emperor Frederick II., and retained by them after the double-headed eagle had become the imperial emblem. The Austrian empire preserved the double-headed eagle (fig. 2) of the earlier German empire. This also was modified at the revolution, but the crown was retained. Russia assumed in 1472 the double-headed eagle under Ivan III. to signify that the tsar sprang from the Greek emperors, who had borne it as a symbol since the partition of the Roman empire. The Russian arms (fig. 3) differ from the Austrian in the eagle's holding only a sceptre in its dexter claw, and being charged with a shield gules, bearing a figure of St George and the dragon. The shield was encircled with the collar of the Russian order of St Andrew, and the wings of the eagle were charged with groups of small shields representing the provinces of the

empire. A white crowned eagle in a red field is the shield of Poland (kingdom and republic); and the United

States of America have adopted a dark-brown eagle with outspread wings, having in one of its talons a bundle of arrows, in the other an olive-branch, bearing on its breast a shield whose upper part is blue and under part silver, and crossed by six red vertical bars (fig. 4). In its beak it holds a band with the inscription

E pluribus unum, surmounted by thirteen stars, the original number of states. In France, the eagle was assumed as his imperial symbol by Napoleon I. (fig. 5), was set aside at his fall,

Fig. 3.—Russian Empire.

restored by Napoleon III. in 1852, and once more abolished by the republic in 1870. The arms of the French empire may be blazoned azure, an eagle rising and respecting to the sinister, grasping in both his claws a thunderbolt all or.

Eagle, a gold coin of the United States of America, of the value of ten dollars, or over forty-one shillings sterling. The double-eagle is a gold twenty-dollar piece. See DOLLAR.

Eagle, BLACK and RED, Prussian orders. See ORDERS.

Eagle-hawk, a name applied to several eagles of comparatively small size, belonging to the genera *Spizæus* and *Morphnus*. They are natives of

warm climates, and are often very beautiful in form and colour. Some species are adorned with well-developed crests extending backwards from the

Eagle-hawk (*Morphnus guianensis*).

crown of the head. Hence they are sometimes called *Crested Eagles*. The crest is well seen in a species of *Morphnus* from Guiana. See **EAGLE**.

Eaglehawk, a mining town of Victoria, Australia, 4½ miles from Bendigo, and 106 NW. of Melbourne, with both of which it is connected by rail. Much gold has been found here in the quartz lodes with which this hilly district abounds.

Eaglehawk and Crow. See **TOTEMISM**.

Eagle-owl (*Bubo*), a genus of large owls. The familiar disc of feathers round the ear is incomplete above, there is a large free tuft on each side, and the feathers on the legs extend down to the toes. The members of the genus are widely distributed, occurring in most parts of the world except Australia. The largest eagle owl (*B. maximus*) has a wide range in Europe and Asia. It is a large and powerful bird, said sometimes to cope with the golden eagle, and to prey upon young deer; in length it may measure over two feet; the colour is rusty yellow, varied with brown and black; its voracity is excessive, and has made it an Ishmaelite among birds.

Eagle-owl (*Bubo maximus*).

The loud weird cry has given origin to the German name *Uhu*, and has been the basis of many evil omens and superstitious terrors. Its favourite haunts are desolate and wooded rocky regions. The eagle-owl of America (*B. virginianus*), the Virginian Horned Owl, is somewhat smaller, but very bold and powerful. It carries off with ease almost any inhabitant of the poultry-yard. It is found in almost all parts of America. See **OWL**.

Eagre. See **DORE**.

Ealing, a parliamentary and municipal borough in Middlesex, 5½ miles W. of Paddington by rail. It is the birthplace of Huxley. Pop. 68,000. Brentford (q.v.) is in this parish.

Ear. The apparatus of hearing, as it exists in man and the mammalia, is composed of three parts—the external ear, the middle ear or tympanum, and the internal ear or labyrinth.

The *external ear* consists of two portions, the *auricle* or *pinna* (the part popularly recognised as the ear), and the *auditory canal* or *external acoustic meatus*.

In man the auricle, on its outer or more exposed surface, presents various eminences and depressions, resulting from the form of its cartilaginous framework. These have received special anatomical names, to which it is unnecessary to advert further than to mention that the deep capacious central space to which several grooves converge is termed the *concha*, and that the lowest and pendulous portion of the ear is termed the *lobe*. The cartilage forming the basis of the external ear consists of one principal piece, in which there are several fissures, which are filled up by fibrous membrane. Several muscles are described as passing from one part of the auricle to another, but they are so little

developed in man that they do not require notice; there are additionally three muscles—the *musculus auricularis superior*, the *m. auricularis anterior*, and the *m. auricularis posterior*, which pass from adjacent parts of the scalp to the ear, and which, though more developed than the previous group, are of little or no real importance in man (at least in his civilised state), but are of considerable use in many mammals. They are rudimentary, and usually functionless.

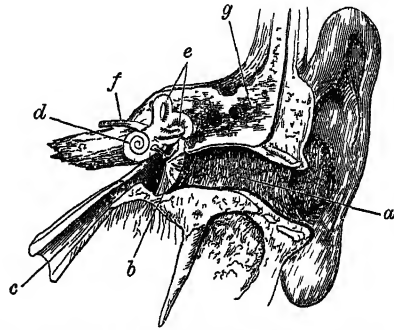

Fig. 1.—Sectional view of the external, middle, and internal Ear, showing the interior of the External Acoustic Meatus, Tympanic Cavity, and Auditory Tube (or Eustachian Tube):

a, the external acoustic meatus; b, the tympanum; c, the auditory tube leading to the pharynx; d, the cochlea; and e, the semicircular canals and vestibule, seen on their exterior by the removal of the surrounding bony tissue; f, auditory nerve; g, temporal bone.

The external acoustic meatus passes from the concha inwards, and a little forwards, for rather more than an inch. It is narrower at the middle than at either extremity, and on this account there is often considerable difficulty in extracting foreign bodies that have been inserted into it. The membrane of the tympanum which terminates it is placed obliquely, in consequence of the lower surface of the meatus being longer than the upper. The canal is partly cartilaginous and partly osseous, the osseous portion consisting in the foetus of a ring of bone, across which the membrane is stretched, and in many animals remaining persistently as a separate bone. The orifice of the meatus is concealed by a pointed process, which projects from the facial direction over it like a valve, and which is called the *tragus*, probably from being sometimes covered with bristly hair like that of a goat (*tragos*); and it is further defended by an abundance of ceruminous glands, which furnish an adhesive, yellow, and bitter secretion, the cerumen or wax, which entangles small insects, particles of dust, and other small foreign bodies, and prevents their further passage into the meatus.

The *middle ear*, or *cavity of the tympanum*, is a space filled with air which is received from the Pharynx (q.v.) through the auditory tube (see fig. 1, b, c), and traversed by a chain of very small movable bones (fig. 2), which connect the membrane of the tympanum with the internal ear. It lies, as its name implies, between the external meatus and the labyrinth or internal ear, and opens posteriorly into the cells contained in the mastoid portion of the temporal bone, and anteriorly into the auditory tube. The cavity is of an irregular shape, and is lined by a very delicate ciliated epithelium, which is a prolongation of that of the pharynx through the auditory tube.

Its external wall is in great part formed by the membrane of the tympanum, which is nearly oval, and placed in a direction slanting inwards, so as to form an angle of about 55 degrees with the lower

and anterior walls of the external acoustic meatus (see fig. 1). The handle of the malleus (or hammer), the first of the chain of ossicles (see fig. 2), is firmly attached between the layers of this membrane in a vertical direction as far downwards as the centre, and by drawing it inwards renders its external surface concave.

Its internal wall has two openings communicating with the internal ear, each of which is closed by a delicate membrane. These openings are termed the *fenestra vestibuli* and the *fenestra cochleæ*, the former leads to the vestibule, and is connected by its membrane with the base of the stapes (or stirrup-bone), the last of the chain of ossicles; while the latter opens into the cochlea.

The ossicles of the tympanum are three—viz. the *malleus*, the *incus* (or anvil), and the *stapes*. We have already explained how the malleus is connected with the membrane of the tympanum by means of its handle. Through this connection, the tension of that membrane may be modified by the agency of a muscle which is attached to this ossicle. This muscle is the *tensor tympani*, which arises from the under surface of the petrous portion of the temporal bone, and is inserted into the medial edge and anterior surface of the

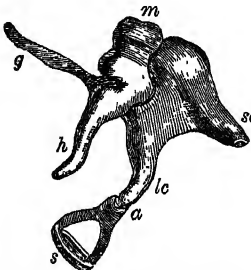

Fig. 2.—Ossicles of the left Ear, as seen from the outside and below:

m, head of the malleus; *g*, the slender process, or *processus anterior*; *h*, the manubrium or handle; *sc*, the short crus, and *lc*, the long crus of the incus; *a*, the position of the lenticular process, through the medium of which it articulates with the head of the stapes; *s*, the base of the stapes. Magnified three diameters.

of the stapes is attached. The *stapes* is almost sufficiently described by the figure. It has a head, neck, two branches, and a base, which, as has been already mentioned, fits into the *fenestra vestibuli*. A minute muscle, the *stapedius*, takes its origin from a hollow conical eminence termed the *pyramid*, which lies behind the *fenestra vestibuli*, and is inserted into the neck of the stapes; its function is probably to act as an antagonist to the *tensor tympani*.

The Eustachian tube, into which the tympanic cavity opens anteriorly, is about an inch and a half in length, and passes downwards, forwards, and inwards to its opening in the pharynx. It is partly osseous, but chiefly cartilaginous. Its chief use is to allow the free passage of air in and out of the tympanum.

The *internal ear* or *labyrinth* is the essential part of the organ of hearing, being the portion to which the ultimate filaments of the auditory nerve (see BRAIN, NERVOUS SYSTEM) are distributed. It is composed of three parts—viz. the *vestibule*, the *semicircular canals*, and the *cochlea*, which form a series of cavities presenting a very complicated arrangement, and lying imbedded in the hardest

part of the petrous portion of the temporal bone. They communicate externally with the tympanum by the two openings already described—the *fenestra vestibuli* and the *fenestra cochleæ*; and internally with the internal auditory canal, which conveys the auditory nerve from the cranial cavity to the internal ear. The very dense bone immediately bounding these cavities is termed the *osseous labyrinth*, to distinguish it from the *membranous labyrinth*, which lies within a portion of it.

The *vestibule* is a common central cavity into which the semicircular canals and the cochlea open (see fig. 3, V). It is about a fifth of an inch in height and in length from before backwards, its transverse diameter (from side to side) being somewhat less. On its posterior wall are five orifices

Fig. 3.—Interior of the Osseous Labyrinth:

V, vestibule; *av*, aqueduct of the vestibule; *r*, macula cribrosa; *s*, semicircular canals; *s*, superior; *p*, posterior; *l*, lateral; *a*, *a*, *a*, the annular extremity of each; *C*, the cochlea; *sl*, osseous zone of the lamina spiralis, above which is the scala vestibuli, communicating with the vestibule; *st*, scala tympani, below the spiral lamina. Magnified $3\frac{1}{2}$ diameters.

for the semicircular canals, one of the orifices being common to two of the canals. Anteriorly, the cochlea enters it by a single opening, partially divided by an osseous partition—the *lamina spiralis ossea*. On its outer wall is the *fenestra vestibuli*, and on its inner are the *maculae cribrosæ*, containing several minute orifices for the entrance of filaments of the auditory nerve.

The *semicircular canals* are three in number, and open into the vestibule by means of five orifices, the two vertical canals having at their non-ampullate extremities a common orifice. They vary in length, and notwithstanding their name, each is considerably more than a semicircle, the superior vertical canal being the longest. The average diameter is about a twentieth of an inch, one extremity of each canal exhibiting a dilatation or *ampulla*. Each canal lies in a different plane, very nearly at right angles to the planes of the other two; they are distinguished from each other by their position, and are named superior, posterior, and lateral.

The *cochlea*, which derives its name from its resemblance to a common snail-shell, forms the anterior portion of the labyrinth. It consists of an osseous and gradually tapering canal, about an inch and a half in length, which makes two turns and a half spirally around a central axis, termed the *modiolus*, which is perforated at its base for the entrance of the filaments of the cochlear portion of the auditory nerve. This spiral canal gradually diminishes towards the apex of the cochlea. At its base it presents an opening into the vestibule, partially divided into two. In

the recent state, one of these openings (*scala tympani*) does not communicate with the vestibule, but is closed by the membrane of the *fenestra cochleæ*. Its interior is subdivided into two passages (*scalæ*) by an osseous lamina. This is the *lamina spiralis*, which incompletely divides the cochlea into an upper passage, the *scala vestibuli*, and a lower one, the *scala tympani*—i.e. the division is incomplete so far as the skeleton goes, but is completed during life by soft parts afterwards to be described. At the apex these two passages communicate by an opening to which the term *helicotrema* has been applied.

We now return to the *membranous labyrinth*. The membranous and osseous labyrinths have the same shape, but the former is considerably smaller than the latter, a fluid, termed the *perilymph*, intervening in some quantity between them. At certain points recent investigations have shown that the membranous is firmly adherent to the inner surface of the osseous labyrinth. The vestibular portion consists of two sacs, an upper and larger one, of an oval shape, termed the *utricle*, and a lower and smaller one, of a globular shape, called the *sacculus*. The membranous semicircular canals resemble in form and arrangement the osseous canals which inclose them, but are only one-third of the diameter of the latter.

It will be remembered that the osseous structure of the cochlea is that of a tube almost but not quite divided into two by the *lamina spiralis* ossea. The division is completed by the *lamina*

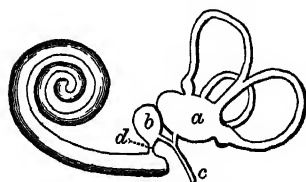

Fig. 4.—Scheme of Mamalian Labyrinth:

a, utricle; *b*, sacculus; *c*, aqueductus vestibuli, dividing into two branches, going to sacculus and utricle respectively; *d*, canalis or ductus reuniens

extremity is connected with the sacculus through a delicate membranous channel known as the *ductus reuniens*. Upon the basilar membrane is situated the organ of Corti, which consists of the following parts (to name only those of most importance) from within outwards: (1) a single row of so-called inner hair-cells; (2) the two rods of Corti (known as inner and outer); (3) four or five rows of outer hair-cells. These are again protected by the curtain-like *membrana tectoria*.

The auditory nerve leaves the medulla oblongata together with the facial, and passing into the internal auditory meatus, divides into two branches, which pass respectively to the vestibule and the cochlea. The former ends in a peculiarly modified epithelium with projecting processes situated in the ampullæ of the semicircular canals and on certain spots within the sacculus and utricle, known as the *maculæ acusticæ*. In the latter situation are also found small crystalline bodies, called

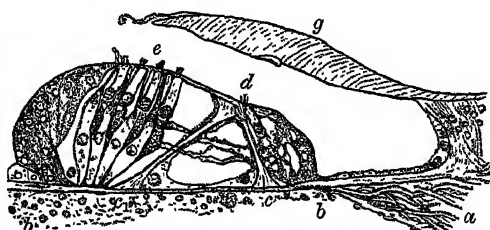

Fig. 6.

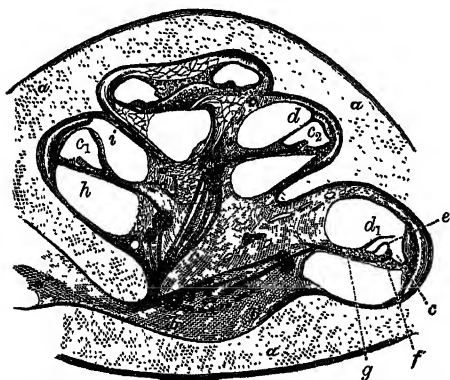

Fig. 5.—Section through the Cochlea of a Human Embryo:

a, *a*, cartilage, which afterwards ossifies; *b*, *b*, tissue, which afterwards becomes the modiolus; *c*-*c*₂, duct of the cochlea; *d*, *d*₁, membrana vestibularis; *e*, membrana tectoria, rather elevated from its proper position; *f*, position afterwards occupied by the organ spirale; *g*, lamina spiralis; *h*, scala tympani; *i*, scala vestibuli.

spiralis membranacea (or basilar membrane). From near the junction of the osseous with the membranous lamina springs the membrane of Reissner, which, stretching across to the wall of the osseous cochlea, shuts off a third space known as the *ductus cochleæ*. The cochlear duct terminates blindly at both ends, but near its lower

otoconia (Gr. *konis*, or *konía*, 'dust'), which are suspended around the maculæ; they consist of small rhombic crystals of carbonate of lime. The cochlear branch of the auditory nerve probably terminates in the inner and outer hair-cells of the organ of Corti (see fig. 6). The sacculus and utricle communicate with each other and with the interior of the skull through the *aqueductus vestibuli*, while the *aqueductus cochleæ* connects the perilymph of the scala tympani with the arachnoid space.

PHYSIOLOGY.—(1) *Of the External Ear.*—A true auricle only exists in the mammalia, and in this class it varies from little more than an irregularly shaped cartilaginous disc with little or no motion, as in man and the quadrumana, to an elongated funnel-shaped ear-trumpet movable in all directions by numerous large muscles, as in the horse, the ass, and the bat. The mode in which we see it employed by those animals in which it is highly developed sufficiently indicates that its main function is to collect and concentrate the sounds which fall upon it. But the experimental investigations of Savart, with an apparatus constructed to resemble the tympanic membrane and the external auditory apparatus, show that these parts are also adapted to enter into vibrations in unison with those of the air; and he suggested that the human auricle, by the various directions of different parts of its surface, could always present to the air a certain number of parts whose direction is at right angles with that of the molecular movement of the air, and therefore is the most favourable position for having the vibrations communicated.

(2) *Of the Tympanum and its Contents.*—Savart's experiments show that the membrane of the tympanum is thrown into vibration by the air, and that it always executes vibrations equal in number to those of the sonorous body which excites the oscillations in the air. He further ascertained that

the malleus participates in the oscillations of the tympanic membrane, and that these vibrations are propagated to the incus and stapes, and thus to the membrane of the *fenestra vestibuli*. The malleus has further the office of regulating, through the *tensor tympani* muscle, the tension of the tympanic membrane; and to allow of the motion necessary for this purpose, we find movable joints between it and the incus, and again between the latter bone and the stapes. The contraction of the stapedius muscle similarly modifies the tension of the membrane of the *fenestra vestibuli*; and as compression or the reverse exercised on this membrane extends to the perilymph, and is propagated through it to the *fenestra cochleæ*, the tension of the membrane of the latter opening is also influenced by the muscle in question. The incus is much more limited in its motions than either of the other bones, and its use seems to be to complete the chain of ossicles in such a manner as to prevent any sudden or violent tension of the membranes, such as we can easily conceive might occur if the conductor between the membranes were a single bone. The presence of air in the tympanic cavity serves a double purpose: in the first place, it preserves a uniform temperature on the outer surfaces of the fenestral membranes, and thus supports a fixed elasticity in them, which would not be the case if they were freely exposed to ordinary atmospheric changes; and secondly, the action of the chain of ossicles as conductors of sound is materially increased by their being completely surrounded by air, as is obvious from the first principles of acoustics; further, were it not for the presence of air within the tympanum, the drum membrane would be arched inwards, and the resulting displacement and change of tension would produce deafness.

(3) *Of the Labyrinth*.—Sonorous vibrations may be conducted to the labyrinth through the bones of the skull; but during the ordinary act of hearing, the movements of the tympanic membrane are propagated through the chain of ossicles and the labyrinth, and thus perceived by the auditory nerve. A considerable amount of mystery surrounds the functions of the sacculæ and utricles. The fact that they are so closely connected with the semicircular canals suggests that, like the canals, they function as organs of equilibration. Breuer has advanced the view that these organs give us information regarding the position of the head when at rest, or when making progressive, as opposed to rotary, movements, and accordingly supplementing the functions of the semicircular canals.

The semicircular canals have been much studied. It has now been conclusively demonstrated that they are intimately associated with the maintenance of the body in the erect position. Injury of a semicircular canal tends to produce rotatory movements of the body and eyes, and it has therefore been suggested that the functions of these organs may be connected with the reflex act of listening, as exemplified in the lower animals by pricking the ears and rotation of the head. From experiments on animals, and observations on the human subject in disease, it has now been proved that a lesion of the semicircular canals is followed by giddiness or vertigo, which manifests itself either in involuntary falling, rotation, or in a subjective condition, during the continuance of which surrounding objects seem to revolve round the patient. It is generally believed by physiologists that the cochlea has the special function of analysing sounds. It has been found that the basilar membrane is not equally broad throughout, but that it increases gradually from base to apex. It therefore presents a series of strings of different lengths, and the short ones are assumed to vibrate in the perception of high notes, while the long ones are stimulated to motion

by low tones. The lower part of the cochlea is therefore chiefly concerned in the perception of sounds of high pitch, while the upper parts respond to those of low pitch. Some observers, however, do not accept this view—e.g. Voltolini and Rutherford, but believe that sounds are analysed in the auditory centre, which, according to the investigations of Munk and Ferrier, is located in the temporal lobe. For the hearing of birds, reptiles, &c., see BIRD, REPTILES, &c.

THE DISEASES OF THE EAR.—It is manifestly impossible to attempt any account of the various individual ear diseases in an article like the present. Since aural surgery has become an exact science, the medical profession have come to realise that such phrases as a 'cure for deafness,' or a 'treatment for earache,' are not only inexact but absurd. Deafness—varying in degree from a slight impairment of hearing up to total inability to perceive sounds—may be due to a great variety of causes, and any of these causes may produce not only deafness, but noises in the head. Thus the auditory canal may be blocked by wax, the products of skin eruptions affecting its lining membrane, tumours, masses of fungus, the results of inflammation, &c. The tympanic membrane may be displaced or thickened, the ossicles may be impeded in their movements by the presence of exudation, or by fibrous adhesions or swelling of the mucous membrane within the tympanum. Then again these parts may be injured either by disease or by violence. The auditory nerve may be affected in any part of its course from the auditory centre to the labyrinth, and thus deafness may result. We have only indicated some of the pathological causes of impaired hearing, but enough has been said to show that before deafness can be prescribed for with any hope of success, an examination of the ear must be made by a competent medical man.

Turning now to earache, let us consider some of its causes. Sometimes it is due to the presence of boils in the auditory canal, or the whole lining membrane of the passage, including the outer layer of the *membrana tympani*, may become inflamed. Perhaps the most common cause of earache is inflammation of the drum-cavity. Such inflammation often stops before the inflammatory products have taken on a purulent character. This mild form is very common in children, and often sows the seeds of deafness in after-life if appropriate treatment be not applied. Occasionally earache is altogether due to the presence of a diseased tooth, which need not necessarily be tender or painful. By far the most dangerous form, however, is that which arises in connection with a so-called 'running ear.' The general meaning of this symptom in such cases is an accumulation of decomposing matter and sometimes diseased bone in close proximity to the brain, and a fatal result is by no means uncommon. Vertigo, or giddiness, is a very frequent symptom of ear disease, and can often be relieved or cured by attention to this organ.

A feeling of fullness in the head, and disinclination for mental effort, is far from uncommon. Rarer or less important symptoms of aural affections are (1) anomalies of taste, owing to involvement of the chorda tympani nerve on its way through the drum-cavity; (2) paroxysmal cough and sneezing; (3) neuralgia of the head; and (4) epilepsy; the last named being fortunately extremely uncommon. We should not be justified in omitting to mention that adenoid vegetations in children are often the cause of deafness. This is all the more important, because such cases when taken early can almost always be cured.

From what has been said, it will be obvious that any remarks we could, without unduly extending

this article, make with regard to treatment would be useless. We feel it, however, to be our duty to warn those who suffer from ear disease from consulting unqualified quacks. This resort to empirics is all the more uncalled for as there are now numbers of respectable highly-qualified practitioners who devote attention to aural maladies.

There are, however, a few points of general interest and of great importance which may be touched upon.

It is a common delusion that it is a dangerous thing to cure a discharge from the ear. Now this is by no means true; indeed it may be at once stated that life is never safe so long as a chronic putrid discharge issues from the ear. In all such cases it is not only safe but necessary to syringe the meatus with a warm disinfecting solution, such as boracic lotion, or water to which some Condy's fluid has been added. The ear should then be dried by carefully introducing a wick of absorbent cotton-wool. The origin of the superstition ament the danger of stopping a discharge is easily explained. If the putrid matter be present, it is better that it should find its way out. Now, if in such a case some physical obstacle prevents its exit, a fatal result is apt to supervene. It had thus been noticed that in many cases the 'running from the ear' stopped before dangerous symptoms set in, and hence the delusion. Another point as to which much misapprehension exists, is the danger caused by the presence of a foreign body in the ear. It has been observed by a noted specialist that 'the point of a dagger in the meatus is less likely to do harm than unskilled efforts to remove it.' No endeavour should ever be made to remove a foreign body which is not seen, and all probing in the dark is to be absolutely avoided. Most extraneous objects can be removed simply by means of warm water and a syringe used by a skilled hand. If the object be a pea, bean, or any other body which is likely to swell from absorbing moisture, it is better not even to attempt syringing, and to wait until skilled advice can be obtained.

Should an insect get into the ear, it can almost invariably be syringed out with warm water, or if a syringe be not at hand, the ear may be filled with warm oil or even water.

Deafness occasionally runs in families, and the symptom is then usually due to chronic thickening of the tympanic structures. Persons in whom this hereditary tendency exists should, on the first indication of ear trouble, seek advice.

It need hardly be said that picking the ears ought to be avoided. This habit may lead to the 'ear pick' being driven through the drum membrane. Should the ear be made to bleed, and should there be any doubt as to whether the drum membrane be wounded, scrupulous care should be taken to prevent the entrance of fluid. If the tympanic membrane be accidentally perforated, syringing, or instilling ear drops is almost certain to be followed by inflammation. After fifty the hearing tends to fall off a little, but except possibly in extreme old age, marked deafness for conversation is always abnormal. It is a curious fact that elderly people who require a watch to be put quite close to the ear, can often hear conversation well. This is explained by the fact that after middle life the auditory nerve is less sensitive, and the power of readily perceiving high-pitched tones is then less acute.

According to the writer's experience, almost complete deafness in one ear, while the other is perfect, does not necessarily endanger the sound organ. Others, however, take the opposite view. It must be remembered that in most cases, impairment of hearing is bilateral, and this is always the case when deaf persons have to be addressed in an elevated voice.

The instruction and training of children who have been born deaf is dealt with in the article **DEAF AND DUMB**.

EAR-TRUMPETS, &c.—The number of ear-trumpets now advertised makes any detailed account of them impossible. The application of one of three principles exists in most, if not all, to wit: (1) a tube with a suitable ear-piece at one extremity, and a more or less conical mouthpiece at the other; (2) a bell-shaped sound-collector, with an ear-piece for insertion into the auditory canal; (3) appliances for tilting the auricle forwards. There can be no doubt that a person who desires to purchase an ear-trumpet will best gain his end by carefully testing a large number of instruments, and choosing that which suits him best.

As a rule small invisible instruments are useless. Politzer has constructed a small tube made of vulcanite and flesh-tinted, the object of which is to prolong the tragus backwards; in a very few cases this is found to be an exception to the above rule. The micro-telephone has been much advocated as an aid to hearing, its use being suggested by the fact that deaf persons often hear telephones well. In many cases, however, it is not of much service, and causes the patient great annoyance by producing a considerable amount of secondary noise. In some cases—those in which the drum membrane is destroyed—the introduction of an artificial drum is useful. The simplest and most effective form of drum (also fortunately the cheapest) consists of a pledget of cotton-wool.

In all cases of marked deafness, when the sight is not defective, the patient may with advantage take lessons in lip-reading. At least thirty are required, besides practice at home.

Ear-cockles. See **WHEAT**.

Earl, a title of nobility now the third in the peerage of the United Kingdom. Among the northern races of Europe a *jarl* or *eorl* was one of the noble class, as opposed to the *ceorl*, who was the mere freeman (see also **THANE**). Of the noble class, a certain number, under the name of *ealdormen*, were made governors and judges over particular districts, and were sometimes designed in Latin phraseology *comites*, sometimes *duces*. William the Conqueror rewarded his chief followers by granting them the lands and also the offices of the Saxon nobles. The office of ealdorman, so long as Norman-French continued to be spoken in England, was, as on the Continent, called *count*, and its holder was considered the *comes* of the sovereign (see **COUNT**); and though the designation earl was afterwards reintroduced, the French term continued to give a name to the district (county) over which the earl presided, and the title of countess to his wife. After, as before the Conquest, each earl, besides having supreme authority under the crown in his own county, had a fixed revenue from it, consisting of the third penny of the pleas. When Geoffrey de Mandeville was made Earl of Essex, the Empress Maud, besides giving him and his heirs the third penny of the shrievalty of the pleas as an earl ought to have within his county, made him and his heirs in direct terms 'hereditabiler' earls of Essex. In other cases, however, down to the reign of King John, an earl was so constituted by a grant of the third penny of the pleas, of which the earldom was assumed to be a pertinent, the words being added, '*unde comes est*,' or '*ut sit inde comes*,' and the newly-created earl was invested with his dignity by girding on the sword, a ceremony which was a survival from Saxon times.

William the Conqueror, by making earldoms hereditary, probably took the first step to convert a title of office into one of dignity. Deputies, *vice-*

comites, or sheriffs had necessarily to be appointed when the earl was a minor, or otherwise incapacitated from discharging his duties, and by degrees the office itself passed to the deputy. In the reign of King John a fixed sum, payable from the profits of the county, began to take the place of the third penny, and the words '*unde comes est*' were supplanted by the words '*sub nomine comitis*,' showing that the official power had ceased, and the dignity only survived. In the reign of Edward III. earldoms began to be created by charter or patent, certain lordships or lands being generally erected into a *comitatus* to descend with the newly-created dignity. But the girding on of the sword as a solemnity of investiture still continued, to which the imposition of a cap of dignity or golden circlet was added in the reign of Edward VI. In 1615 these ceremonies were declared unnecessary, and in the reign of Queen Anne it became the practice to insert a clause in patents expressly dispensing with them.

Until late in the reign of Edward III. earldoms were limited by the charters constituting them to heirs-general, and an heir-female often succeeded, her husband generally obtaining the title of earl; but in the case of more co-heirs than one, the lands were divided, and the dignity, which could not subsist without them, reverted to the crown. So inseparable at that period were the lands from the dignity, that there seem to be one or two instances where the title was taken away on the ground of poverty. But in fact the will of the crown at times diverted the succession from its regular channel, and occasionally the rights of the heir were suspended for a time and then recognised.

Towards the end of the 14th century it became the rule for patents of earldom to be limited to the heirs male of the body of the grantee, the title on their failure merging in the crown; and there are a few occasional instances of the dignity being conferred for life. The title of countess, more than any other degree in the peerage, has from time to time been conferred for life on females. The idea of earls being territorial officers has been so entirely departed from that the designation bestowed on them is occasionally (as in the case of Earls Grey, Nelson, Spencer, Russell, and Cairns) their own surname with the prefix earl.

In Scotland the earl was the successor of the Celtic *moruar* or great steward, who was first a tributary king, and afterwards a hereditary judicial officer placed over a certain territory. In the reigns of Alexander I. and David I. the *moruar*s gradually assumed the title of earls or *comites*, while vice-comites or sheriffs were appointed, who, if they did not at once supersede them, at least exercised a concurrent jurisdiction with them. Seven earls are enumerated by their names, not titles, in the foundation charter of the abbey of Scone in 1114; and during the 12th century there existed a body called the Seven Earls, with whose sanction the king acted. With the introduction of feudalism, the earls passed into the position of feudal lords, holding the lands with which their connection had at first been judicial as an earldom of the crown. The creation of additional earldoms formed a part of the feudalising process; and though the earldoms continued to be spoken of as seven, those enumerated were not always the same. The coronation of Alexander II. (1214) is the latest date at which the earls are specified as seven in number; and their functions as advisers of the sovereign were afterwards merged in those of the '*communitas*.'

Earldoms continued territorial much longer in Scotland than in England. From the beginning of the feudal period down nearly to the 17th century, the title was usually conferred by the erection of certain lands into an earldom, the charter but

rarely making specific mention of the dignity of earl. In 1578 the practice first became general of introducing the title of earl into the charter; and from that date till 1600 half the charters of earldom in the Register of the Great Seal (they are eighteen in all) make special mention of it. Patents of the dignity of earl after the English fashion were first introduced in 1600, the earliest being that of the Earl of Winton. The older earldoms, like lands and other heritable subjects, passed to heirs of line; and in the case of co-heirs the lands were divided, the dignity with the principal messuage passing to the eldest. The husband of a countess was often, though not always, designed by the courtesy title of earl.

An earl's mantle is scarlet with three doublings of ermine. He is styled the 'Right Honourable,' and in formal documents the sovereign usually designs any peer of the degree of an earl as 'Our trusty and well-beloved Cousin,' an appellation which originated in the reign of Henry IV., who was either by descent or alliance related to every earl in the kingdom. An earl's eldest son takes as a Courtesy Title (q.v.) one of his father's inferior titles. The younger sons take 'The Honourable,' with Christian name and surname added, and the daughters 'Lady,' with Christian name and surname. See ADDRESS (FORMS OF), CORONET.

Earle, JOHN (1601?-65), probably the best and most humane of English character-writers (see CHARACTER), was born in York, studied at Oxford, was chaplain and clerk of the closet to Charles II. in exile, and bishop first of Worcester and then of Salisbury. His anonymous *Microcosmographie* appeared in 1628.

Earle, JOHN (1828-1903), philologist, born at Elston, South Devon, was educated at Plymstock, Plymouth, Kingsbridge, and Magdalen, Oxford, took a first in classics (1845), was elected a fellow of Oriel (1848), and was professor of Anglo-Saxon in 1849-54 and again permanently from 1876, being also a prebendary of Wells.

Earle, WILLIAM, was born in Liverpool in 1833, entered the army in 1851, and served through the Crimea; he held several staff appointments abroad, and was military secretary to the governor-general of India in 1872-76. Promoted major-general in 1880, he commanded the garrison of Alexandria in 1882-84, and was killed leading a column of the Gordon rescue expedition in 1885.

Earl Marshal. See MARSHAL.

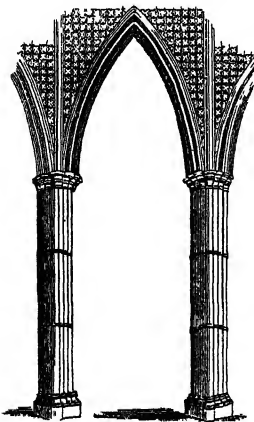

Earlom, RICHARD, mezzotint engraver, born in London in 1743, was a pupil of Cipriani, and early began his art under the patronage of Boydell. He engraved over sixty plates, which were very popular, and are still highly esteemed by collectors. He died in 1822. Among his works was a fine series of prints from the originals of Claude Lorraine's *Liber Veritatis*.

Earlston, or **EROLDOUNE**, a village of Berwickshire, 4 miles NNE. of Melrose, with a railway station and manufactures of ginghams, woollens, &c. Between it and Leader Water is a fragment of the 'Rhymer's Tower,' the traditional abode of Thomas the Rhymer (q.v.); whilst one mile south is Cowdenknowes, with its 'bonny broom.'

Early, JUBAL ANDERSON, Confederate general, was born in Virginia in 1816, graduated at West Point, and served in the Florida and Mexican wars. During most of the years 1838-61, however, he practised law in his native state. On the outbreak of the civil war he entered the Confederate service as a colonel, and commanded a brigade at Bull Run, and a division at Fredericksburg and Gettysburg. In 1864, after some successes, he was

defeated by Sheridan in several battles; and, Custer having also routed him at Waynesboro in March 1865, he was relieved of his command a few days later. He returned to legal practice, and died 2d March 1894. See *Life* by R. H. Early (1913).

Early English, the term generally applied to the form of Gothic in which the pointed arch was first employed in Britain. The Early English succeeded the Norman towards the end of the 12th century, and merged into the Decorated (q.v.) at the end of the 13th. Its characteristics are beautiful and peculiar. Retaining much of the strength and solidity of the earlier style, it exhibited the graceful forms without the redundancy of ornament which latterly degenerated into a fault in the Decorated. Generally, it may be said to bear to the Decorated something like the relation which an expanding rosebud bears to a full-blown rose. The pointed arch was introduced in the 12th century in the north of France, when it was found convenient in enabling the cross vaulting of oblong spaces to be carried out, so that the ridges of the groins might all be kept at the same height. The wall ribs being pointed, led to the windows within them being made of the same form, and thus the pointed arch came to be gradually adopted in all the wall openings. The windows are long and narrow, and are often acutely pointed, when they are called lancet windows. When gathered into a group, they are frequently surmounted by a large arch, which springs from the extreme mouldings of the window on each side. The space between this arch and the tops of the windows is often pierced with circles, or with trefoils or quatrefoils, which by degrees led to the development of tracery. Each window, however, is generally destitute of any tracery in itself. 'The mouldings,' says Parker, 'in general consist of alternate rounds and deeply-cut hollows, with a small admixture of fillets, producing a strong effect of light and shadow.'—*Glossary of Architecture*. From the same work we borrow the accompanying illustration of two very beautiful piers, surmounted by a lancet-shaped arch, and decorated in the manner peculiar to the style. They are from Westminster Abbey. Circular windows are much used, and trifoliated archways over doors are also to be found, as at Salisbury Cathedral. By far the most characteristic decoration of the style is the Tooth-ornament (q.v.), which is often used in great profusion. Where foliage is used, it is conventionally treated and cut with great boldness, so as to throw deep shadows, and produce a very fine effect. The under-cutting is

Early English Piers and Arch.

often so deep as to leave nothing to connect the leaves with the mouldings but the stalks, and occasionally the edge or point of a leaf. The caps of the columns are often composed of mouldings only, and are circular in plan, both of which features distinguish Early English from the Early Pointed style of France. The buttresses are more prominent than in the Norman style, and pinnacles and flying buttresses are introduced. The term Early English is said to have been introduced by Mr Millers in 1805. It corresponds to *Ogivaie primi-*

tive of French writers, and is very often known as the First Pointed or lancet-arched amongst ourselves. See *GOTHIC ARCHITECTURE*.

Earn, a river and loch in the south of Perthshire, in the finely-wooded, beautiful valley of Strathearn. Loch Earn lies to the north of Ben Vorlich; its eastern extremity is 24 miles west of Perth. Lying 306 feet above sea-level, it is 6½ miles long from east to west, from a half mile to nearly a mile broad, and 287 feet deep; it is surrounded by bold and rugged hills. The river Earn flows east from the loch 46 miles through the strath, past Comrie, Crieff, and Bridge of Earn, into the estuary of the Tay, 7 miles south-east of Perth. Its waters contain salmon, trout, perch, and pike.—The Bridge of Earn, a much frequented village, stands on the right bank of the river, 4 miles SSE. of Perth, and near the saline springs of Pitcaithly.

Earnest (in Scotland, *ARLES*) is a sum of money given in token that the parties to a bargain are in earnest (though 'earnest' in this sense is etymologically distinct), and mean their agreement to be binding. The contracts in which earnest is most frequently given are sale and service. Earnest is not the same as part payment; it is something given 'to bind the bargain;' whereas it is plain that there can be no part payment until the bargain is concluded. It is also necessary to distinguish between 'dead earnest'—i.e. some small gift or payment made by way of evidence of the bargain, and the payment of a sum to be deducted from the price if the bargain is completed, to be forfeited by the purchaser if he fails to complete. For the English law on this subject, see Benjamin on *Sale*; for the Scots law, Eiskine's *Institutes*. The term 'earnest' is sometimes used to include the symbolical acts of hand-shaking, thumb-licking, &c., by which, in various countries, consent to a bargain is or has been signified.

Ear-ring, a ring suspended from the ear by a hook passing through a hole bored for the purpose, or (latterly) by a clamp. They were used by both sexes among the Persians, Babylonians, Lydians, Libyans, and Carthaginians. They were always worn by the Greek women, from Hera in the *Iliad* down to the Venus de Medici, whose ears are pierced for the reception of ear-rings. Pliny tells us that there was no part of dress on which greater expense was lavished amongst the Romans. Many Egyptian ear-rings of very beautiful design have been preserved, and these antique designs have often been imitated in modern times. During the reigns of Elizabeth and James I., ear-rings were worn in England by men, a custom which is still continued by many sailors. Otherwise, at the present day in England and the United States they are worn only by women. The ears are bored usually at about seven years of age. The boring is still popularly believed to be a valuable remedy in cases of sore eyes, by producing counter-irritation. This idea, however, is without satisfactory evidence in its support, and certainly there are much more efficient and beneficial methods of producing the desired effect.

Ear-shell. See *HALIOTIS*.

Earth is the name applied to the third planet in order from the sun. This planet is of unique importance as the dwelling-place of man, and is the only portion of the universe of which we have direct knowledge. Like other members of the solar system, the earth revolves in an elliptical orbit round the sun in a definite plane termed the plane of the Ecliptic (q.v.). The mean distance of the earth from the sun has been calculated from the Transit of Venus observations in 1874 and 1882 as 92,800,000 miles. The minimum distance,

attained in December, is 91,250,000, and the maximum in June, 94,500,000, the difference, or 3,250,000 miles, is the eccentricity of the earth's orbit or the extent of its departure from a circle. The earth is accompanied by one satellite, the moon, at a mean distance of 238,800 miles.

Figure of the Earth.—It was anciently believed that the earth was a flat disc of land (see PROLEMAIC SYSTEM), surrounded by a great world-river (Oceanus), but the theory of a flat earth has been abandoned by all but a few fanatics. The earth's figure may be popularly said to be that of a ball; many irregularities in form make it impossible to speak of it strictly as a sphere or even a spheroid. In consequence of the dip of the horizon, the field of view—the boundary line of which is a circle in all parts of the earth—becomes wider as the height of the observer increases. On a wide, smooth surface also, such as the sea or a great plain, the upper part of a distant receding object remains in sight when the lower part has disappeared. These facts, being verified experimentally in innumerable places scattered over the earth's surface, can only be explained on the assumption that the earth is like a ball. On travelling northwards or southwards from any place, the position of the stars, their daily path in the heavens, and the time of rising and setting are altered; and new stars, altogether invisible before, come into view as the traveller proceeds. This also can be explained only by the rotundity of the earth. The most convincing proof to the popular mind is, however, that the earth has been circumnavigated by vessels steering always in the same general direction.

If the earth were a sphere or perfect ball, the arc of the surface subtending an angle of 1° at the earth's centre would be equal in every part of the circumference. The angle in degrees subtended by any arc of a meridian can readily be found astronomically (see LATITUDE), and the length of this arc in ordinary lineal units such as feet or metres can be accurately measured (see GEODESY). This has been done in several places, and the result (see DEGREE) shows that towards the north and the south the degree becomes longer than it is near the equator. It results that the earth is flattened somewhat at the poles and projects in the equatorial region. Delicate experiments at sea-level by means of the spring-balance or the pendulum show that the force of Gravitation (q.v.) is greater in high than in low latitudes. A standard mass weighed in a spring-balance is heavier in Greenland than in Brazil, even after making the necessary correction for the result of centrifugal force (see CENTRE). Since the mass of the two attracting bodies remains the same, their centres must be nearer at the station where the weight is greater—i.e. the polar regions must be flattened so as to lie nearer the earth's centre than is the equator. The extent of the flattening is such that the polar diameter is approximately $\frac{1}{23}$ shorter than the mean equatorial diameter, a deviation from the form of a sphere far too slight to be detected by sight or touch in any model which is small enough to be seen at one view. Accurate measurements of degrees of longitude in tropical regions suggest that the equator is not a circle, as it would be if the earth's figure were that of an oblate spheroid, but an ellipse of very slight eccentricity (estimated by some calculators as $\frac{1}{10000}$, by others as $\frac{1}{2000}$), the longer diameter running from about the meridian of Ireland to that of New Zealand.

The earth's surface is ridged and wrinkled with innumerable irregularities, so that the simile of an orange with its slightly corrugated rind, its flattened poles, and slightly irregular equator gives a very fair idea of the form. The surface of the sea,

supposed to be produced through the continents, would give the geometrical figure of the earth or *geoid*. For 'sea-level,' see CONTINENT.

Dimensions.—Supposing the earth to be an oblate spheroid or ellipsoid of revolution, its polar or shortest diameter has been determined as 7900.2 miles, sufficiently near the value of 500 million inches to be conveniently remembered. The longer, or equatorial mean diameter is 7926.9 miles, a difference of 27 miles. The vertical distance between the greatest natural height and hollow (Mount Everest, and a point in the Pacific Ocean near the Ladrones) amounts to $11\frac{1}{2}$ miles, or $\frac{1}{23}$ of the mean diameter.

The meridional circumference of the earth is 24,856 miles, and the Metre (q.v.) was intended to be $\frac{1}{10000000}$ of this distance, though really made somewhat shorter. The circumference at the equator is 24,899 miles, and this is the longest distance which can possibly be travelled in a direct line over the surface. The total area of the earth's surface calculated from these dimensions is 197 million square miles, and the corresponding volume 260,000 million cubic miles.

Mass of the Earth.—The problem of measuring the mass or amount of matter in the earth is one of peculiar interest. The usual mode of measuring mass is by means of weight or the attraction of the earth on bodies, and this method is of course inapplicable in determining the mass of the earth itself. The method that is employed is to compare the attraction of gravity between two known masses, and between one of these masses and the whole earth. The simplest method is by observing the deviation from the vertical of a plumb-line near an isolated mountain. The volume of the mountain is first found by survey, and its density calculated from the geological structure and the density of its component rocks. Observations have been made on Chimborazo, on Schiehallion in Perthshire, and on Arthur's Seat, with fairly concordant results. Airy in 1834 made experiments in a coal-pit at South Shields, and Von Sterneck in 1882-85 in deep shafts in Austria, on another principle. The rate of vibration of a pendulum at the surface depends on the attraction of the earth as a whole; but at the bottom of a shaft the same pendulum will vibrate at a different rate for two reasons: (1) faster, because it is nearer the centre; (2) slower, as the attracting mass is less. The spheroidal skin of the earth's crust equal in thickness to the depth of the shaft ceases to exert any influence, and the force of gravity due to this spheroidal shell is the difference between the force measured by the vibration of the pendulum at the surface and that at the bottom of the mine. If then the mean density (and hence the mass) of this spheroidal skin can be ascertained, the problem would be solved; but this it is impossible to do in a satisfactory way, and so the experiment is vitiated, and the results compare badly with other methods. Professor P. G. Tait pointed out that an excellent opportunity of making an experiment of a similar kind is afforded on the shores of estuaries where there is a high rise of tide—e.g. the Bay of Fundy. It would be easy to estimate the gravitational influence exerted by the alternate piling up and clearing away of a readily calculated mass of water.

The most satisfactory method of finding the mass of the earth is that devised by the Rev. John Mitchell, but carried out carefully by Cavendish, and hence known as the 'Cavendish Experiment.' It consists of measuring very accurately the minute attraction exerted by two large spheres of metal on two much smaller metal balls fixed to the extremities of a light lever which is suspended by a wire. The slight attraction of the large spheres is

measured by the Torsion Balance (q.v.), of which the smaller balls form part, and the distance of the attracting bodies is known. Hence, making the proper allowance for distance in each case, the attraction of the large spheres on the small balls is to the attraction of the earth on the small balls—i.e. the *weight* of the small balls—as the mass of the large spheres is to the mass of the earth. The attraction measured is so minute that the most elaborate precautions are necessary to get a definite result. Cavendish used leaden spheres a foot in diameter, which were swung round so as to exert their attraction alternately on opposite sides of the torsion balance. The apparatus was much simplified by Cornu, who alternately filled with mercury and emptied hollow iron spheres suitably placed with regard to the small balls. When Professor C. V. Boys succeeded in making extremely fine quartz fibres he applied them in the construction of a torsion balance of such extreme delicacy that in 1895 he repeated the Cavendish experiment with an apparatus little more than one foot square, and obtained the best results yet secured. Von Jolly and later Mr J. H. Poynting made a modification of this experiment by using an ordinary Balance (q.v.) of great delicacy, with double scale pans, the lower pan of each pair being suspended by a fine wire from the centre of the upper. In the simplest form the experiment was conducted thus: on the right-hand side this fine wire is surrounded by a massive perforated cast-iron cylinder built up in sections. On standard masses being placed in the upper pans, the one on the right-hand side is *heavier* by the attraction of the iron; then when the masses are changed to the lower pans the right-hand mass is *lighter* by the attraction of the iron, so that the difference of weight represents twice the attraction. The iron cylinder is then taken to pieces, and built up round the left-hand wire, and the process repeated several times.

Mean Density of the Earth.—The result of all these experiments shows the mass of the earth to be approximately 6,000,000,000,000,000,000 tons. The mean density calculated from this mass, and the known volume of the earth, is a more manageable figure, and may be given as an example of the degree of accordance in the various measurements. The values arrived at by the various experimenters varied between 4.86 and 5.56. The average of the concordant results yielded by the best methods may be taken as 5.5, the density of pure water at 4° C. being 1. The density of surface rocks is only about 2.5, but lavas of deep origin have densities ranging up to 3 or even higher, and it follows that the density becomes greater towards the centre. The whole earth is bound together mainly by the force of gravity, cohesion being of much less importance, and the pressure at great depths is so enormous, that at the centre it is calculated to amount to 15,000 tons per square inch. At this pressure the density of the ordinary rocks would be far greater than the mean density of the earth will warrant, so that instead of being obliged to suppose that all the heaviest metals have accumulated at the centre in order to account for the high mean density, we have to seek in the elevated temperature of the interior a reason for the mean density being so small as it is. The density of the crust of the earth is irregularly distributed. It must be greater under the Pacific Ocean, in order to balance the projecting mass of Africa and Europe on the opposite side of the world, otherwise, the globe would be lop-sided. In many places observations with the pendulum or plumb-line show discrepancies that cannot be accounted for by the configuration of the neighbouring surface, and must be due to irregularities in the density of the crust. The dimensions given

refer to the earth as a perfectly smooth figure, the solid lithosphere being surrounded by a fluid shell, the hydrosphere, about 2 miles thick, which is included in the estimate, but this is unwrapped by the Atmosphere (q.v.), which is of undefined extent, and is left out of account.

Constitution of the Earth.—The elements present in the earth are, as far as can be ascertained, the same as those in the sun and other members of the solar system. Of the ninety or more elements recognised by chemists, very few occur free in those parts of the crust accessible to us, except the oxygen, nitrogen, and argon of the atmosphere. The hydrosphere (5000 of the mass of the earth) is composed of about 97 per cent. of pure water, a compound of hydrogen and oxygen. The lithosphere is made up mainly of silicates—i.e. compounds of silicon, oxygen, and a few metals. The table shows, according to Prestwich, the approximate composition of the crust of the earth; but more recent estimates give a larger proportion of iron:

As Elements.		As Oxides, &c.	
1. Oxygen..	50.0	1. Silica	53.0
2. Silicon ..	25.0	2. Alumina	19.0
3. Aluminium..	10.0	3. Lime.	6.3
4. Calcium.....	4.5	4. Magnesia. . . .	5.8
5. Magnesium..	3.5	5. Soda	2.5
6. Sodium.....	2.0	6. Potash.	2.4
7. Potassium. .	1.6	7. Carbonic acid	} ... 7.5
8. Carbon	}..... 2.4	8. Iron oxides	
9. Iron		9. Sulphuric acid	
10. Sulphur		10. (Chlorides)	
11. Chlorine	}..... 1.0	11. Other oxides. .	3.5
12. Other elements...			
	100.0		100.0

The character of the rocks composing the lithosphere varies with depth. Beneath the outer part of the crust composed of sedimentary or metamorphic rocks, there seems to occur a zone of acidic lavas—i.e. rocks in which the proportion of silica is greater than is required to saturate the bases. At greater depths, basic lavas of greater density occur, in which there is a deficiency of silica. The thickness of the crust, and the constitution of the earth beneath it, can only be guessed at from superficial indications, or by deductions from its movements. The change of temperature with depth has been carefully studied (see TEMPERATURE), especially by the Committee on Underground Temperatures of the British Association, who have collected great masses of data, and shown that as a rule beneath the stratum of invariable temperature (which lies at a variable depth, and is the limit of solar influence), the temperature increases at the rate of about 1° F. in every 55 or 60 feet. There are indications of this rate diminishing at great depths. The deepest depressions of the oceans extend about 6 miles below sea-level, and it might be expected that the heat of the earth's crust would raise the temperature of the water there, and keep up, if not a boiling sea, at least energetic oceanic circulation. This is found not to be the case, as the cold water from the polar regions has long since cooled down the bed of the open oceans to a temperature everywhere between 30° and 40° F. When a tunnel is bored horizontally through a mountain, the temperature in the interior is found to be higher than corresponds to its distance from the centre of the earth, but quite in accordance with the depth beneath the summit of the mountain. Although the temperature in the interior of the earth is unquestionably high enough to melt, and possibly even to vaporise all known substances, the fact that the melting-point of rock-materials is raised by pressure makes it probable that the earth as a whole is a solid body, and is not merely a thin hard crust like an egg-shell encircling a vast molten sphere. Astronomical observations, and the investigations on

earth-tremors and tides, indicate that the lithosphere, as a whole, has a rigidity approximately equal to that of steel. The theory of a solid earth in no way hampers the explanation of Volcanoes (q.v.) emitting vast quantities of fused rock-materials, as these may be relatively small accumulations of fluid rocks here and there, or more likely some temporary relief of pressure lowers the melting-point, and allows the rocks to liquefy explosively. Considerations of the thickness and rate of deposition of stratified rocks have suggested that the crust has been solid for about 1000 million years. Lord Kelvin, arguing from the rate of loss of heat, allowed less than 100 million; but the discovery of radium and the remarkable thermal effects of radio-active minerals deprives this line of reasoning of all quantitative value, and a greater age must be conceded. The transformation of radio-active elements supplies a new measure for the antiquity of the earth, and Lord Rayleigh deduces an age of several thousand million years by this method for the earth while in a condition to support life. This figure gives the geologists sufficient elbow-room for their processes. See GEOLOGY, NEBULÆ.

The Surface of the Earth.—After a solid crust had been formed, the contraction consequent on cooling caused the core of the earth to shrink away, parts of the unsupported crust either fell into the cavities formed, or were drawn in by the contracting nucleus, and so gave rise to hollows and ridges on the surface. The oceans conceal so much of the earth's surface from our view, that we are apt to form a wrong idea of its real configuration. If the hydrosphere were of one quarter its present extent, only the deepest hollows would be covered with water, and all the rest would be land, while, if it were four times as extensive, even the highest ridges would be submerged. As it is, the emergent ridges or land areas amount to 28 per cent. of the entire surface, with a mean height of about 2300 feet above the sea, and the submerged hollows occupying the remaining 72 per cent. of surface have an average depth of about 11,500 feet beneath sea-level. The distribution of land and water is such that the land is massed mainly in the northern hemisphere, the Arctic Circle having the largest proportion of land in its course, nearly seven-eighths of its length; the equator crosses land only for one-sixth of its length, and the parallel of 57° S. runs entirely over sea. If the world were divided into two hemispheres, with the English Channel at the centre of one and New Zealand at the centre of the other, the proportion of land to sea in the former would be twelve to thirteen, and it would contain seven-eighths of the land; the proportion of land to sea in the latter would be one to twelve, and it would contain three-quarters of the sea of the globe. The question of the permanence of the main lines of surface-features is referred to in CONTINENT and in SEA. Sir John Murray's discussion of the height of land and depth of sea has been supplemented by estimates by Professors Wagner and Krummel. According to Wagner's classification the *Depressed Area* or ocean deeps more than 16,400 feet below sea-level occupy 3 per cent. of the earth's surface, the *Oceanic Plateau* depths between 7400 and 16,400 feet occupy 54 per cent., the *Continental Slope* between 660 and 7400 feet 9 per cent., the *Continental Plateau* between 660 feet below and 3300 feet above sea-level 28 per cent., and the *Culminating Area* above 3300 feet 6 per cent. Unsurveyed regions leave some doubt as to the exact figures. The total volume of ocean is fourteen times as great as that of dry land; if all the land were levelled down to sea-level, only one-fourteenth of the oceanic depressions would be filled up. For the comparative area of land and water, see SEA.

Movements of the Earth.—The fact that the earth rotates always in the same way gives the globe *polarity*, or the property of two-endedness, and the fact that the axis of rotation coincides with the shortest diameter of our planet, strongly confirms the nebular hypothesis by indicating that the earth assumed its existing form, approaching an oblate spheroid, by rotating rapidly about its present axis while in a fluid or at least a plastic state. The rotation of the earth gives the power of distinguishing and defining directions. The direction towards which rotation takes place is the east, that from which it takes place is the west. These terms are purely relative. Compared with Britain, America is the western continent; compared with Japan, it is the eastern continent; there is nothing like an east or west pole. The ends of the earth's axis are fixed points—one called the north pole, the other the south pole. The north pole is defined as that end of the axis which points towards a bright star in the constellation of the Little Bear, the star being named in consequence Polaris, or the Pole-star (see LATITUDE, POLES). While the rate of angular rotation is uniform in all parts of the earth, namely, one complete revolution in 24 sidereal hours (or in 23 hr. 56 min. 4 sec. solar time), or 15° per hour, the tangential velocity varies with the cosine of the latitude. At the equator, with its circumference exceeding 24,000 miles, the velocity of a point on the surface of course exceeds 1000 miles an hour. At the parallel of 60°, which is only half the length of the equator, the tangential velocity is 500 miles an hour, while at the poles themselves there is no tangential velocity, but rest as far as axial rotation is concerned. In virtue of inertia, the property of matter defined in Newton's first law of motion, the direction of the axis of a rotating body tends to remain unchanged. As the earth has a rapid motion of revolution round the sun, varying from a maximum in perihelion to a minimum in aphelion, the plane in which it moves also tends to remain unchanged, and these two directions afford standards in space to which the inclination of all other planes and lines may be referred. The eccentricity of the earth's orbit is subject to changes, maxima of eccentricity occurring at irregular intervals of about half a million years, but its plane is much more constant. The time occupied by the earth in its circuit of 580 million miles is one year, or 365 days, 6 hours, 9 minutes, which implies an average velocity of 66,000 miles per hour.

The inclination of the earth's equatorial plane to the plane of the ecliptic is 23° 28', and the variations are scarcely perceptible. The most important of the earth's motions resulting from perturbations by other heavenly bodies, is Precession (q.v.), which is due to the differential attraction of the sun and moon on the bulging equatorial region. This attraction constantly tends to turn the earth's axis at right angles to its orbit; but it results only in a slow rotation round a perpendicular axis which occupies about 25,800 years, and has the effect of making the pole describe a circular path in the heavens. The possibility of changes in the inclination of the earth's axis having taken place within recent periods, is a question of great importance with regard to geological climate (see GLACIAL PERIODS); but the balance of evidence seems to be against the probability of any such change. Astronomical observations indicate a movement of the poles over the surface of the earth at the rate of a foot per annum, within a circle of about 50 feet in diameter, giving rise to minute variations in latitude. The proofs of the diurnal rotation of the earth are numerous and complete. A consequence of rotation from west to east has been deduced by Ferrel to the effect that any body

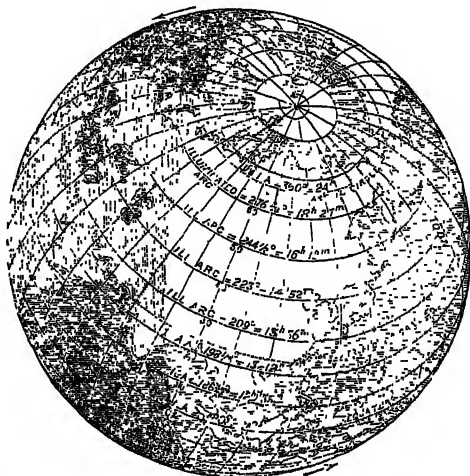

moving on the earth's surface, in whatever direction, tends to deviate from a straight path towards the right in the northern hemisphere, and towards the left in the southern. For bodies moving towards or from the equator, this can be easily understood. Suppose an ocean current to start from the equator, flowing due north. At the equator it has, if the earth rotates from west to east, a much greater eastward velocity than has the part of the earth's surface to which it flows, so that it must of necessity flow eastward as well as northward—i.e. it must turn towards the right as it proceeds. Similarly moving southward from the equator, the current must retain an easterly drift as it advances, thus deviating to the left. This is the mode of circulation which actually takes place in the oceans. Many large rivers of the northern hemisphere, such as the Volga, press harder on the right bank, which is accordingly steep and always receding, while the left bank is a more gentle slope. The same thing is observed in a more marked degree in the case of winds; and even in gunnery, allowance has to be made for the deviation of the projectile from this cause. The fact that a bullet dropped from a lofty tower falls a little to the east of the vertical, has been repeatedly verified, and can only be accounted for by the upper part of the tower having a greater tangential eastward velocity than the base, on account of its being farther from the earth's centre, this greater velocity being shared in by the dropping bullet. But the most convincing proof was given by Foucault with the Pendulum (q.v.). A long and heavy pendulum swings in a plane, the direction of which is by Newton's first law of motion constant in space. Yet when such a pendulum is set swinging in a room, its plane of vibration very soon appears to be changing. The plane always appears to twist round in the same direction, and since we know that the plane of the pendulum does not change, we must conclude that the room turns round it in consequence of the rotation of the earth. Direct proofs of the revolution of the earth round the sun are less simple. The Aberration of Light (q.v.) proves that the observer accomplishes some yearly journey at a rate that is comparable, though remotely, with the velocity of light; and the parallax of some of the nearer stars when corrected for aberration, indicates that we view them at opposite seasons of the year from opposite ends of a line, 180 million miles long.

The earth performs none of its motions with rigorous precision. The solar system is so balanced and knit together that each of its members exerts some influence in determining the movements of all the rest. See PERTURBATIONS.

Distribution of Solar Energy on the Earth.—The energy of the sun continually beating upon the earth keeps up the circulation of the atmosphere and hydrosphere, through which it acts on the lithosphere and becomes available for the use of living creatures. Only a small fraction of the energy actually given out by the sun is intercepted by the earth, but this minute fraction is great enough to produce enormous results. As the globe rotates, one half is always exposed to sunlight, one half always immersed in darkness. The refractive power of the atmosphere makes the rising or setting sun appear higher than its true position in the sky, and so keeps it visible for a longer time than if there were no air. The length of the day and the amount of daylight in high latitudes are thus very considerably increased.

Not considering the effect of refraction, it is easily understood how at the summer solstice of the northern hemisphere, when the north pole is inclined towards the sun, sunlight falls $23\frac{1}{2}^\circ$ beyond the pole, and as the earth rotates all this region remains in daylight the whole twenty-four hours.

At this time the south pole is turned from the sun to the same extent, and no light can reach within $23\frac{1}{2}^\circ$ of the south pole. The circles bounding those regions of continuous daylight or darkness at the solstices are termed the Arctic and Antarctic circles, and the space within them the North and South Frigid zones. At the summer solstice of the northern hemisphere the sun is vertical at a distance of $23\frac{1}{2}^\circ$ N. of the equator. This is the highest north latitude at which a vertical sun is experienced, and is termed the Tropic of Cancer from the constellation in which the sun appears at the time. At the

View of Earth from the zenith of a point in 50° N. lat. and 90° E. long. at 6 o'clock A.M., on its summer solstice (21st June):

The figures on the parallels of latitude indicate the length of the illuminated arc in degrees, and the period of daylight (longest day) in hours.

winter solstice of the northern hemisphere the sun is vertical at a distance of $23\frac{1}{2}^\circ$ S. of the equator or on the Tropic of Capricorn, which is the highest south latitude for a vertical sun. As the sun appears overhead in all places between these circles twice in the year, and thus exerts its maximum heating power, this broad belt of the earth is termed the torrid zone. Between the tropics and the polar circles there are two regions, each 43° wide, in which the sun is never overhead, nor is it ever beneath or above the horizon continuously for a period of twenty-four hours. These are the northern and southern temperate zones. In high latitudes the sun's rays strike the earth's surface obliquely, and have thus less heating power than in low latitudes (see CLIMATE; see also DAY and SEASONS). The northern winter and southern summer occur in perihelion, so it might be supposed that more heat reaches the southern than the northern hemisphere. Kepler's second law explains, however, that the earth moves so much more rapidly when near the sun than it does when distant from that centre, that the amount of heat received in equal times is the same in both cases.

Work of Solar Energy.—The sun's heat-power is constantly at work breaking down the rocks of the higher parts of the lithosphere, and spreading the triturated substance as soil over the lower ground. The circulation of water is the great instrument for this work; vapour raised from the oceans and carried by wind is condensed as rain on the high-lands, and returning to the sea in the form of springs and streams, has a chief share in wearing down the surface of the land. This process would ultimately reduce all the land to a uniform

low level, were it not counteracted by the continual gentle elevations and depressions of the surface, consequent on internal changes (see UPHEAVAL). The energy of the sun acting through living plants enables these to recombine the elements of the soil and the air, and thus to form a variety of new products, most of which can as yet be produced in no other way. Thus the greater part of the land surface of the earth is covered with growing vegetation. The distribution of plants over the earth's surface depends on configuration, climate, and soil. Where these conditions were favourable, great stores of solar energy have been laid up in the potential state by the preservation as fossils of ancient forests. Coal is the best example, and the distribution of coal is at present one of the most important factors in the life of a modern manufacturing community. Animal life, which is ultimately dependent on plant-life, and cannot get energy from the sun direct, carries on the process of rearrangement and redistribution of matter farther. It also has had a share in producing the present condition and aspect of many parts of the earth. The chalk, limestone, and marble which characterise many regions of the land, and the coral reefs and islands of tropical seas, are immediate consequences of the action of animal life. The distribution of plants and animals in their natural state is determined solely by the physical conditions of their surroundings; but the actual distribution has been greatly modified by the action of man.

Man to a large extent modifies and reverses the ordinary course of natural phenomena and the laws of Geographical Distribution (q.v.). The greatest density of human population would occur naturally in those regions where the means of life are most abundant and most easily obtained, such as the alluvial plains of hot regions; hence the valleys of the Nile and Ganges and the plains of China have always been amongst the most populous parts of the world. With the development of means of transport and of manufacturing processes a drift of population set in towards regions of mineral wealth, so that in manufacturing countries, such as western Europe and the eastern United States, the coal-fields are most densely peopled, and the population is fed by grain and flesh raised in far distant parts of the earth. Tribes of the human race early began to claim exclusive rights to the region of the earth's surface they inhabited, and definite districts of the earth have from remote historical times been associated with particular races, who either continue to hold them if strong enough to resist invasion, or are superseded by more powerful immigrants. The artificial boundaries of countries appeal so much more strongly to the popular mind than the natural boundaries of such regions of the earth's surface as plains, plateaus, or river-basins, that until recently in most atlases the maps were coloured to show only the arbitrary human divisions. It is the purpose of Geography (q.v.) to consider the earth in its special relations to man.

The intense manufacturing activity of modern life has an important bearing on the future of the earth as a habitable planet. Mineral fuel and metals are being extirpated and consumed with great and increasing rapidity, and from many causes they are being produced and stored up at a slow and decreasing rate. Hence, to view the subject from the standpoint of geological time, the supply of potential energy is approaching an end. The sun pours upon the earth every day enormous quantities of energy, continually available in wind and water power, and these must be utilised more and more as the accumulated reserve of energy in coal and metals diminishes. In the same way vegetation is a regenerative process; but by the destruction of forests without replanting and the

exhaustion of soils the availability of solar energy in this way has been destroyed in some parts of the world, and greatly impaired in others. It is necessary, in viewing the earth as a home for man, to bear in mind that if it is to continue capable of maintaining its present population in comfort—not to speak of the increase at the rate of about 10,000,000 a year—the stores of potential energy must be carefully preserved, and care must be taken to allow the daily solar supplies to produce their fullest effect by applying the principles of forestry and agriculture.

The Future of the Earth.—The principle of the degradation of energy as stated before the possibilities of radio-activity were known, taught that the earth will gradually cool down. The sun also cooling, although at a slower rate (about 1° in 3000 years), will gradually reduce the supply of external energy, the friction of lunar tides will lengthen the rotation period of the earth until it coincides with its reduced period of revolution round the sun. Ultimately, if this principle holds good, all the bodies of the solar system will clash together, restoring by the impact much of the potential energy to the kinetic state, and in so doing they will start a reduced duplicate of the old solar system, with a less supply of energy. The cycle of nebula, sun, and planet will go through the same round again and again with diminishing speed, until ultimately in the course of infinite time all the matter of the universe will be accumulated in one vast mass, with all the energy of the universe uniformly diffused through it at one level of temperature and utterly unavailable, and the universe will be dead.

The internal composition and gradual changes of the interior, the somewhat complicated distribution and mode of origin of the surface irregularities of the lithosphere, the various motions of the earth as a whole, and the action, modified by all these conditions, of solar energy on the atmosphere, hydrosphere, and lithosphere, determine all the changes of the earth's condition and appearance, including its relations to living plants and animals. The investigation and description of these features and their rationale constitutes the study known to the Germans as *Erdkunde*, to the French as *Physique de Globe*, and in this country by the unsatisfactory and inadequate names of physical geography and physiography.

Earth-houses, or YIRD-HOUSES, the name which seems to have been generally given throughout Scotland to the underground buildings, which in some places are called also 'Picts' Houses' (q.v.), and in others, it would appear, 'Weems,' or caves. Martin, in his Description of the Western Islands, printed in 1703, when their use would appear to have been still remembered, speaks of them as 'little stone-houses, built under ground, called

earth-houses, which served to hide a few people and their goods in time of war.' The prehistoric earth-house of the Scottish mainland, however, is a long narrow gallery of a curved form, increasing in height and in width from the entrance to the farther end. These cave-like structures, which are sometimes over 80 feet in length, are built of unhewn and uncemented stones, roofed by unhewn flags, and entered usually at the narrow end. When the chamber is unusually wide, the side-walls converge, one stone overlapping another, until the space at top can be spanned by stones of 4 or 5 feet in length. In some cases the earth-house shows two or more chambers, communicating with one another by a narrow passage. Occasionally, as many as forty or fifty earth-houses are found in one group, as in the moor of Clova, not far from Alford, in Aberdeenshire. They are generally so near the surface of the ground that the plough strikes upon the flagstones of the roof, and thus leads to their discovery. The objects most frequently found in them are those of domestic use or personal ornament, and the refuse of food. The indications afforded by the character of the relics assign the occupation of the earth-houses in Scotland to post-Roman times. Occasionally, the surface of the ground beside the earth-house shows vestiges of dwelling-houses, and folds or inclosures for cattle. This, with other things, would indicate that the earth-houses of Scotland and Ireland (for they are found also in that island) were put to the same purpose as the caves which, as Tacitus (writing in the 2d century) tells us, the Germans of his day dug in the earth, as storehouses for their corn, and as places of retreat for themselves during winter, or in time of war. For plans and descriptions of many earth-houses in Scotland, see Anderson's *Scotland in Pagan Times: the Iron Age* (1883).

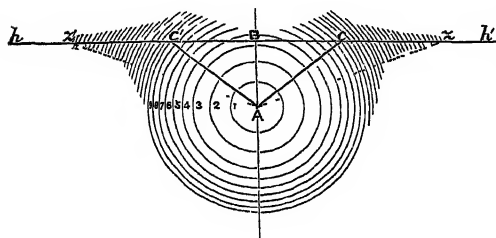

Earth-nut, a popular name of the tubers of certain umbelliferous plants, particularly *Bunium bulbocastanum* and *B. flexuosum*, which are common in most parts of Europe. Names of the same signification are given to them in a number of European languages. *Arnut*, *Yernut*, *Ground-nut*, and *Jurnut*, Scots and English provincial names, are corruptions of earth-nut. *Pig-nut* and *earth-chestnut* are also common English names. They are wholesome, nutritious, sweet, starchy, and very slightly acrid on the palate. When boiled or roasted they are delicious; cooked in the latter way under embers they resemble chestnuts, but are more aromatic, and generally preferred to them by the inhabitants of countries where both are indigenous. In Holland, the Alps, and in some parts of England, particularly in Hertfordshire and Cambridgeshire, where they are plentiful, they are used in soups. They form an article of trade in Sweden, and have sometimes been recommended as worthy of an attention which they have never yet received in Britain. The two species are very similar in general appearance, although *B. bulbocastanum* has by some botanists been referred to the genus *Carum*, because its carpels have single vittæ between the ribs, *B. flexuosum*, with three, to *Conopodium*. The former is also a plant of stouter habit. Both have umbels of small white flowers, much divided leaves with very narrow segments, and a single roundish tuber at the root of each plant. *B. flexuosum* is common in woods, pastures, waysides, &c., in most parts of Britain. *B. bulbocastanum* is found only in some of the chalk districts of England, but is abundant in many parts of Europe. *B. ferulaceum* likewise affords tubers, which are used as food in Greece.—The somewhat similar tubers of another umbelliferous plant, *Oenanthe pimpinelloides*, which grows in the pastures of some parts of the south of England, are sometimes also used for food, notwithstanding the

very poisonous qualities of some of its congeners (see *WATER-DROPWORT*).—A Himalayan umbelliferous plant (*Cherophyllum tuberosum*), a species of Chervil (q.v.), yields edible tubers or *earth-nuts*.—The name earth-nut is sometimes extended to other small tuberous roots of similar quality although produced by plants widely remote in the botanical system, as *Apios tuberosa* and *Lathyrus tuberosus*; as also to the very different Ground nut (q.v.) or Ground-bean, the *Arachis*.

Earthquake, the term applied to any tremor or shaking of the ground. Many earthquakes are so gentle as to pass almost unrecognised, others again are sufficiently pronounced to excite general remark or alarm, without, however, causing any damage, while some spread enormous destruction over wide areas. Probably no part of the earth's surface is entirely free from vibration, but, fortunately, destructive earthquakes are confined to comparatively limited regions. According to Mallet, the well-known authority upon seismology (*seismos*, 'an earthquake,' *logos*, 'a discourse'), the almost universal succession of phenomena recorded in notable earthquakes is first a trembling, next a severe shock, or several in quick succession, and then a trembling gradually but rapidly becoming insensible. In most cases, each shock lasts only a few seconds, but the tremblings that follow may be continued for days, weeks, or even months. Noises of sundry kinds usually precede, accompany, or succeed an earthquake. These have been variously described, some likening them to the howling of a storm, the growling of thunder, the clanking and clashing of iron chains, the rumbling of heavy wagons along a road, the shattering and crashing of enormous masses of obsidian or glass, &c. Such noises are conducted through the ground, or they may travel through the sea, or be transmitted through the air. They are often propagated through the ground for very great distances, so that they may be heard in regions far removed from the disturbed area. Cases are on record where such sounds have travelled more than 158 geographical miles. Some earthquakes, however, are not attended by any subterranean sounds. This has been the case with some of the most destructive South American disturbances. Thus at the time of the terrible shock which destroyed Riobamba in Ecuador on 4th February 1797, a complete silence reigned. On the other hand, subterranean sounds may be heard without any earthquake being perceived. Humboldt tells us that at Guanajuato, in Mexico (1784), the inhabitants were terrified by loud subterranean thunder, which continued for more than a month, but was not accompanied by any trace of earthquake. The noise ceased gradually as it commenced, and was curiously local, as it was not heard at the distance of only a few miles.

Earthquakes are felt either as *vertical shocks*, from below upwards, as *horizontal* or *lateral shocks*, or as *undulatory movements*. As illustrating the force of a vertical shock, it is related that in 1837, at the fort of San Carlos in Chile, a flagstaff which was sunk for 30 feet in the ground, and secured with iron rods, was violently shot into the air, leaving a round hole in the ground. Again, at the time of the great earthquake of Riobamba, the bodies of many of the inhabitants were projected across the river and fell upon La Culla, a hill over 300 feet in height. During the Calabrian earthquake of 1783, the undulatory motion was well marked by the way in which the trees swayed to and fro, their branches touching the ground. The same appearance was noted at New Madrid (Missouri) during the earthquakes of 1811-12, where the trees were observed bending as the earth-waves passed under them, and immediately afterwards recovering their

position. Numerous observations of this kind have led physicists to the belief that an earthquake is a wave or true undulation of the crust. The wave produced by the original impulse travels outwards

Earth-waves :

h, the horizon ; *A*, centum ; *B*, epicentrum ; *AB*, *Ac*, *Ac'*, *Az*, wave-paths ; 1, 2, 3, 4, &c., spherical concentric shells, or similar phases of the earth-wave. The most destructive effects upon buildings are produced at some point between the epicentrum, *B*, and *z'* or *z*, say at *c'* or *c*.

in all directions from the 'focal cavity,' or 'centrum,' *A*, in successive spherical shells (1, 2, 3, &c.), the form of which, however, as we shall see presently, is subject to many modifications. The point or area on the surface of the ground directly above the 'origin' or centrum is called the 'epicentrum,' *B*, and it is at this point where usually the shock is felt as a vertical stroke coming from below upwards. As we recede from this point, the direction of motion becomes more and more horizontal, and gradually also decreases in intensity until it becomes insensible. Away from the epicentrum, then, it is obvious that the earth-wave at every point comes up obliquely from below—the radial lines along which an earthquake is propagated from the centrum being called 'wave-paths,' *AB*, *Ac*, *Ac'*, *Az*, etc. If the earth's crust were composed of perfectly homogeneous materials, then the undulations propagated from the centrum would extend equally in all directions, and might be shown diagrammatically by describing a series of concentric circles round the epicentrum. But the crust is very far from being homogeneous. It is composed of different kinds of rock, arranged often in very discordant ways, and traversed by irregular joints, fissures, cavities, and dislocations. All these differences affect the transmission of an earthquake; and the direction of motion is still further influenced by the configuration or varying topographical features of the disturbed districts. Thus geological structure and topographical features combined lead to continual deflections and delays of the earth-wave; but inasmuch as the topography of the surface is fundamentally influenced by the nature and structure of the underlying rocks, we may assign the irregularities of the isoseismic circles primarily to geological causes. Hitherto we have been supposing that the earth-waves are propagated in successive spherical shells, the shape of which is modified in various ways. We must remember, however, that the impulse may not originate from a point or spherical cavity, but from a fissure inclined at a considerable angle from the vertical. In such a case the waves, even in a homogeneous medium, would not be concentric circles, but, originating from all points of the fissure, would spread outwards in *ellipsoidal shells* to the surface, where the waves would take the form of ovals or distorted ellipses. In such a case as this, the greatest effect of shock would not be felt in the area vertically above the centrum, but rather to one side of the epicentrum; in other words, the direction of greatest effect would coincide with the

major axis of the ellipsoidal shells. As a matter of fact, isoseismic lines, or lines of equal disturbance, are seldom circles; elliptical or irregular curves being the common forms. And that their form is greatly influenced by geological structure and topography, is shown by the circumstance that earthquakes are propagated not unfrequently in lines or zones—the major axis of elliptical areas of disturbance often having a general direction parallel to the trend of some great valley or considerable mountain-range. In the South American earthquakes, the vibrations are confined to the long narrow strip of low ground between the Andes and the sea, and are not felt on the eastern side of the mountains. Similarly the earthquakes that shake the coast lands of Venezuela, Caraccas, and New Granada are rarely transmitted inland across the coast-ranges.

The velocity of propagation of an earthquake is very variable. Thus in the case of the earthquake of Lisbon in 1755, it seems to have considerably exceeded 1000 feet per second, while in the Lisbon earthquake of 1761 the rate was three times greater. At Tokio, in 1881, the velocities, as estimated by Professor Milne, varied between 4000 feet and 9000 feet per second. From his own observations, taken in connection with those of previous investigators, Milne thought we might conclude (1) that different earthquakes, although travelling across the same country, have velocities which may vary between several hundreds and several thousands of feet per second; (2) that the same earthquake travels more quickly across districts near to than far from its origin; (3) that the greater the intensity of shock, the greater is the velocity.

Various attempts have been made to estimate the depth at which earthquakes originate. Mallet was of opinion that the centrum of the Neapolitan earthquake of 1857 was probably 5½ miles from the surface. His calculations were based on the assumption that the earth-wave radiated in straight lines from the centrum. Immediately above the centrum the wave-path was supposed to be vertical, while at points at different distances from the epicentrum the wave-paths would be oblique, and emerge at different angles at the surface. These angles he obtained by drawing lines at right angles to the direction of the large cracks and rents observed in numerous buildings. The lines so drawn converged approximately to a point below the area of greatest disturbance (epicentrum)—the point of convergence indicating the site of the original impulse or earthquake centrum. The same eminent physicist thought that an earthquake centrum probably never exceeded a depth of 30 geographical miles. According to Professor Milne, the angles of emergence of the earth-waves obtained during the Yokohama earthquake of 1880 showed that the depth of origin of that earthquake might be between 1½ and 5 miles; and he gives a table, compiled from the writings of various observers, which exhibits the mean depths at which certain earthquakes have originated. These estimated depths range from 17,260 feet to 127,309 feet. Two of these depths were obtained by Mallet's method, and four were made by the assistance of Seebach's method, which depends, amongst other things, on the assumption of exact time-determinations, direct transmission by waves from the centrum, and a constant velocity of propagation. Milne's conclusion, however, was that even if the observations of time be practically accurate, yet the other assumptions may often lead to errors of such magnitude that the calculated results may be of but little value.

The area disturbed by an earthquake is generally proportionate to the intensity of the shock.

The great earthquake of Lisbon disturbed an area four times as great as the whole of Europe. In the form of tremors and pulsations, Mr Milne remarks, it may have shaken the whole globe.

Mr Mallet made a preliminary subdivision of all the earthquakes recorded in his great catalogue (British Association Report, 1854) into three classes, as follows: (1) *Great earthquakes*, in which large areas were shaken violently, numerous cities destroyed, and multitudes of people killed, rocky masses dislocated, and powerful secondary effects produced; (2) *mean earthquakes*, sometimes with a wide superficial area, but doing less damage to cities, and attended by scarcely any loss of life, and effecting little or no change on natural objects; (3) *minor earthquakes*, in which buildings were shaken and sometimes fissured, but natural objects were not at all affected, and which left few or no traces of their occurrence after the shock. The first class may be assumed to have a sensible diameter of about 1000 to 1200 miles; the second about 400 miles; and the third about 100 or 150 miles. These of course are only mean results made upon the assumption that the areas of disturbance had sensible surface-boundaries approaching to irregular circles or ellipses. When we come to the great earthquakes of modern times, the boundaries of which have been approximately ascertained, we find that these have been sensible in certain surface radii, or great circles, over 18°, or perhaps even 20°.

Earthquakes are not confined to the land. Many, perhaps the larger number, seem to originate under the sea, particularly along lines parallel to the shores of continents and islands that rise abruptly from great depths. In a violent submarine earthquake, the ordinary earth-wave and sound-wave are accompanied by sea-waves. When the earth-wave is started, a great sea-wave is generated at the same time, while a sound-wave is produced in the air. These waves travel shorewards at different rates. The earth-wave, carrying on its back a small 'forced sea-wave,' is the first to reach the shore, and as it passes inland, it causes a slight recession of the sea as the 'forced wave' slips from its back. The 'great sea-wave' is the last to reach the shore. Its appearance is generally heralded by the flowing back of the sea—the recession varying from 30 or 40 feet or less in some cases, to several miles in others. The time taken for the withdrawal of the water from the shore is equally variable—sometimes it is only a few minutes, in other cases half an hour, or even several hours have elapsed before the appearance of the great sea-wave, or waves. These waves may be 20, 60, or even 80 feet higher than the highest tide, and are usually more dreaded than the earthquake shock itself in such regions as the maritime districts of South America. The greatest sea-wave on record is that which, on October 6, 1737, is said to have broken near Cape Lopatka, at the south end of Kamchatka, 210 feet in height.

The changes which earthquakes produce on the earth's surface deserve the careful attention of the geologist. By causing landslips, and now and again producing crevasses in the ground, they occasionally interrupt or even entirely revolutionise the drainage system of a country, and have thus frequently led to many modifications of a land-surface. Very considerable changes are likewise caused by the great sea-waves which so frequently accompany the violent disturbances of low-lying maritime tracts—blocks of rock, shingle, gravel, and sand, and marine organisms being often swept inland for great distances beyond the reach of the highest tide. Permanent elevations and depressions of the land are sometimes accompaniments of earthquakes. Thus, after the great

earthquakes of 1750, the coast of Chile was found to have been permanently raised from three to four feet. Well-known examples of permanent depressions are those of the Runn of Cutch and the coastlands near Chittagong, which were submerged suddenly during the Bengal earthquake of 1762.

Earthquakes are of most common occurrence in volcanic and mountainous regions. The 'great belt of fire' which circles round the shores of the Pacific Ocean marks out for us the most earthquake-shaken regions of the globe. Professor Milne draws attention to the fact that the shores of those regions slope into the sea at a much steeper angle than the shores of countries where earthquakes seldom occur. Looking at the broad features of the globe, he says, we see on its surface many depressions. Some of these saucer-shaped hollows form land surfaces, as in Central Asia; the majority, however, are occupied by the oceans. Now, most earthquakes seem to have their origin on or near the bottom of these slopes; but to this rule there are of course exceptions.

When we come to inquire into the cause of earthquakes, we are left very much to conjecture. Some earthquakes may be due to the sudden collapse of underground cavities. Some doubtless are associated with volcanic explosions, which for long were held to be, directly or indirectly, the cause of all great earthquakes. Investigation has shown clearly, however, that volcanic explosions are distinctly local in their effects, and, moreover, that earthquakes are more numerous and more potent in non-volcanic than in volcanic regions. Most authorities agree that the chief cause of great earthquakes is to be found probably in the snapping of rocks subjected to great strain. The destruction of Messina and Reggio may be taken as an example. The affected area lies close to one of the great lines of folding of the Alpine system, and the earthquake in all probability was due to a settling down along lines of fracture of the depressed area which forms the Tyrrhenian sea. Many other causes of earthquakes besides those already referred to have been suggested. Amongst these are the attractive influences of the sun and moon, fluctuations in temperature, and the pressure of the atmosphere, &c. But according to Professor Milne, exogenous phenomena such as these play but a small part in the production of earthquakes—their greatest effect being to cause a slight preponderance in the number of earthquakes at particular seasons. Thus, most earthquakes occur during the cold months or winter, and it is then also that barometrical fluctuations are most numerous.

EARTH-TREMORS are vibratory motions of the ground so gentle as seldom to be perceived without the aid of instruments. These microseismic movements appear to be experienced in every region where scientific observations have been made, and may be common to the surface of the whole globe. Their cause has not been determined. They may be due, according to Professor Milne, to slight vibratory motions, the result of the bending or crackling of rocks, produced by their rise upon the relief of atmospheric pressure. Another notion is that they may be caused by an increased escape of vapour from the molten matter under the earth's crust consequent upon similar relief of pressure.

EARTH-PULSATIONS are another set of phenomena discussed by Milne. According to him, these pulsations are slow but large wave-like undulations travelling over or disturbing the surface of the globe. Their existence may be indicated by changes in the levels of seas and lakes, by pendulums, by delicate levels, &c. Some of these pulsations are attributable to earthquakes, while on the other hand certain earthquakes are attributable to earth-pulsations. Thus, according to Milne, the short

quick vibrations of the Lisbon earthquake which overthrew the cities of Portugal had, by the time they had radiated to distant countries, become changed into long flat waves, having a period of perhaps several minutes. These movements were too gentle to be perceived, except in the effects produced by tipping up the beds of lakes and ponds.

Among memorable earthquakes may be noted that of Lisbon, 1st November 1755, which left the city a heap of ruins, destroyed 35,000 lives, and was felt from the Madeiras to Britain; that which destroyed Aleppo in 1822; that at Mount Ararat in 1840; at Brussa, Asia Minor, in 1855; at Quito, 1859; Mendoza, South America, 1860; Manila, 1863; in Peru, 1868; Cúcuta, in Colombia, 1875; Manila, 1880; Valparaíso, 1880; Ischia, 1881 and 1883; at the eruption of Krakatau, 1883; Colchester, 1884; Málaga and Granada, 1884 and 1885; Charleston, 1886; Japan, 1891; Assam, 1897; NW. India, 1905; San Francisco, 1906; Valparaíso, 1906; Messina and Reggio, 1908-9; Turkey, 1912; Central Italy, 1915; Mexico, 1920; China, 1920; Japan, 1923. Milne reckoned that there is at least one earthquake daily in Japan, and probably from twenty to fifty daily on the earth's surface. Buildings are specially erected to withstand earthquakes in Japan, South America, and elsewhere; and similar principles have been applied even to lighthouse-building.

The Seismometer (q.v.) will be described under that head.

See Humboldt's *Cosmos and Travels*; Mallet's *Reports to the British Association* (1850-52, 1854, 1858, 1861); Milne's *Earthquakes* (1898) and *Seismology* (1899); F. Fouqué, *Les Tremblements de Terre* (Paris, 1838); Dutton's *Earthquakes* (1904); Davison's *A Study of Recent Earthquakes* (1905) and *British Earthquakes* (1924); and Hobbs's *Earthquakes* (1908).

Earths, the name applied by the alchemists and earlier chemists to certain substances now known to be oxides of metals, which were distinguished by being infusible, and by insolubility in water. The term was made to include the oxides of calcium, strontium, and barium, which undergo chemical change by contact with water, and yield alkaline solutions. On account of this property these oxides were called the alkaline earths. The term earth is now disappearing from modern text-books of chemistry. See SOILS.

Earth-shine, the light by which the dark portions of the moon's surface are rendered faintly luminous for a few days before and after new moon, resulting in an appearance popularly known as 'the old moon in the new moon's arms.' It is caused by the light reflected to the moon from the sunlit surface of the earth. It is stronger before than after new moon. See MOON.

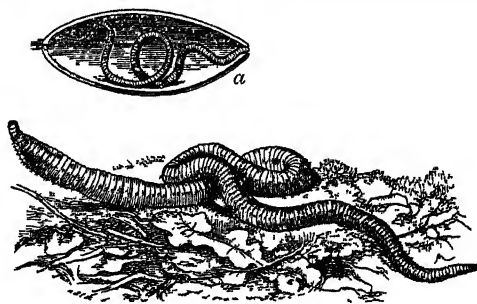

Earthworks. See CAMP, CASTLE, FORTIFICATION, HILL-FORTS; also such books as Windle, *Remains of Prehistoric Age in England*, Mis Armitage, *Early Norman Castles*, Hadrian Allcroft, *Earthwork of England*, the 'Victoria County History,' and the reports of the Earthworks Committee of the Congress of Archaeological Societies.

Earthworm, a general name for terrestrial Oligochæta, or Chætopods with a relatively small number of bristles. There are many genera, such as *Lumbricus* and *Allolobophora*, which are well represented in Britain.

Structure.—A common earthworm, such as *Lumbricus herculeus*, shows a body with many rings or segments, a transparent, often iridescent, cuticle, a sensitive hood or prostomium overhanging the mouth, a swollen glandular 'saddle' or clitellum, four double rows of minute bristles or setæ, and a terminal anus. By contracting its well-developed

muscles, some of which are connected with the bristles, the animal moves along the surface of the soil, sticking its bristles like pins against the ground. Its burrowing progress underground is helped by its habit of eating the soil as it goes, and the head is also used as a lever. The body-cavity is divided by cross partitions into segments corresponding to the external rings.* The food canal has a number of distinct parts: first, the muscular pharynx, by aid of which the worm grasps leaves or stones; then the gullet, with three pairs of lateral lime-glands, which act chemically upon the food; then the swollen crop; then the muscular mill or gizzard where the soil is ground up; and lastly, the long digestive portion, covered with yellow cells, which are familiar to those who pierce the worm with the hook. The nervous system exhibits the usual dorsal brain, ring round the gullet, and ventral chain of double ganglia, with numerous lateral nerves. There are no special sense organs, but the worms are sensitive to light, and though they have no ears, they disappear 'like rabbits into their holes,' when somehow aware of vibrations on the ground or even in the air. The circulatory system is well developed. The excretory system is represented by a pair of small kidney-tubes (*nephridia*) in almost every segment; through these waste particles may be by means of cilia removed from the body-cavity to the exterior. The reproductive organs are hermaphrodite and complex.

Habits.—Earthworms are shy of the light, and keep underground during the day. Of the activity of their nocturnal peregrinations the abundant trails left on the damp soil bear witness. At night they often keep their tails fixed in the mouth of the burrow, while they explore with their bodies in a circle round about. They feed on vegetable matter in the soil, on leaves, &c.; the food is chemically

Common Earthworm :
a, young worm escaping from the cocoon.

acted on by the gullet-glands, ground up in the gizzard, digested in the intestine; the debris is expelled in the familiar castings. A number of eggs, along with spermatozoa and albumen, are surrounded by a common cocoon, which is formed from a secretion of the skin. The cocoon is stripped off towards the head of the worm by contractions of the body, and when it is freed the ends close. There is no asexual reproduction, but the animals are able to regenerate a lost head or tail. Some species of *Lumbricus* exhibit superficial Phosphorescence (q.v.). Leaves are frequently carried below ground, sometimes for food, but also for making the burrows comfortable. Darwin's observations showed that the earthworms display considerable dexterity in seizing even strange leaves in the manner most convenient for transport. Stones of relatively large size are cleverly moved along, and used to protect the mouths of the tunnels. Moles and birds are their chief enemies. Gregarinida (q.v.) are always found parasitic in the male reproductive organs,

and little threadworms are common in the kidney-tubes.

Related Forms.—Besides *Lumbricus* and *Allolobophora*, of which many species occur, there are numerous other genera, such as *Perichaeta*, *Cryptodrilus*, *Acanthodrilus*, *Eudrilus*, *Criodrilus*, and *Alma*. The great *Anteus* of South America is several feet in length, the African *Ilyogenia* only an inch. An Australian species (*Megascolex gippslandicus*) measures towards 6 feet, and produces a gurgling noise as it retreats underground.

Geological Importance.—Earthworms have strong claims to be ranked as the most useful animals. They were ploughers before the plough. In the long past they have made a great portion of our most valuable soil, and now they are improving and renewing it without ceasing. They burrow and open the way alike for the rain-drops and the plant-roots; they bruise the soil particles in their gizzard mills, and liberate the mineral elements. They are continually burying the surface by titurated castings brought up from below. The importance of their humble labour is sublime. This was long ago appreciated by Gilbert White and Jenner, but was only realised after Darwin's marvellously patient observations. Some of these lasted about thirty years. The result was to show that earthworms have been the principal agents in the formation of vegetable mould. In some cases vegetable mould does seem to accumulate without much aid from earthworms, and the constant rain of dust, as Richthofen emphasised, must not be overlooked; yet there is not a shadow of a doubt as to the momentous action of earthworms as soil-makers. Darwin showed that there are on an average over 53,000 worms in an acre of garden, that ten tons of soil per acre pass annually through the bodies of the inhabitants, that they bring up mould from below at the rate of 3 inches thickness in fifteen years. Greater results have seldom been demonstrated by the adding up of infinitesimal items. Darwin's loving patience included many most interesting observations on the habits of earthworms, and his whole work most clearly shows that the truth of nature is stranger than romance. The archaeologist owes the worms thanks for the way in which they have buried and thus preserved tessellated pavements and other antiquities. The use of worms to anglers needs no comment.

'Earthworms, though in appearance a small and despicable link in the chain of nature, yet, if lost, would make a lamentable chasm. . . . Worms seem to be the great promoters of vegetation, which would proceed but lamely without them, by boring, perforating, and loosening the soil, and rendering it pervious to rains and the fibres of plants, by drawing straws and stalks of all kinds into it; and, most of all, by throwing up such infinite numbers of lumps of earth. . . . Worms probably provide new soils for hills and slopes where the rain washes the earth away. . . . The earth without worms would soon become cold, hard-bound, and void of fermentation; and consequently sterile.'—Gilbert White, 1777.

'It may be doubted whether there are many other animals which have played so important a part in the history of the world as have these lowly-organised creatures.'—Darwin, 1881.

See Darwin, *The Formation of Vegetable Mould through the action of Worms* (Lond. 1881); Vejdovsky, *System und Morphologie der Oligochaeten* (Prague, 1844); Perrier, 'Lombriciens Terrestres,' *Nouv. Arch. Mus. Hist. Nat.* (Paris, viii. 1872); Beddard, *Monograph of the Oligochaeta* (1895), and *Earthworms and their Allies*.

Ear-trumpet. See **EAR**.

Earwig, a general name for members of the family *Forficulidae*, often ranked with cockroaches,

&c., in the order *Orthoptera*, often kept in a special order *Dermaptera*. The body is elongate; the segments are imbricate; the hind-wings are folded in a very complicated way under the leathery forewings or tegmina, but wingless forms are common; there is a pair of forceps or callipers or the like at the posterior extremity of the body; the young form is very like the adult.

The common earwig (*Forficula auricularia*) is best known for the pincer-like organ at the end of the abdomen. This is sometimes used in defence, giving a slight nip; and it is also of service in packing up the hind-wings. The forceps are larger and more curved in the males. The hind pair of wings serve for rare flight; they are much larger than the firm front pair, and are folded when at rest in a complex way, not only like a fan, but also transversely. When folded up they are almost completely covered by the anterior pair. The shape of the expanded hind-wing is somewhat ear-like, and this has given origin to the improbable etymology which regards earwig as equivalent to earwing.

Earwigs avoid the light, and do most of their work in the dark. They feed on decaying vegetable and animal matter, and sometimes nibble flowers to get at the nectar. They are given to seeking shelter in crevices, and are thus readily caught in artificial shelters provided for their destruction. They are very sensitive to tobacco smoke. In spite of their names—*earwig*, Ger. *Ohrwurm* ('ear-worm'), Fl. *Perce-oreille* ('pierce-ear'); the Armenian name also means 'ear-enterer'—they are not known to enter the ears of sleepers.

The eggs of the common species are laid in spring, fifteen to twenty, in some convenient cavity. These are carefully watched, and some naturalists have stated that the mother tends the newly hatched young as a hen her chicks.

The distribution of the common earwig is very wide, and the same is true of the order. The largest European species (*F. gigantea*) measures about an inch in length. A little earwig (*Labia minor*) is common in Britain and elsewhere, and may be often seen flying on warm summer afternoons. In the genus *Chelidura* the hind-wings are lost, and the front pair rudimentary. *Labidura* is another important genus.

Easdale, a small isle on the west coast of Argyllshire, in the Firth of Lorn, 16 miles SW. of Oban. It contains $1\frac{1}{2}$ sq. m., and is separated from the much larger Seil Island by a channel 400 yards wide. It is noted for its great slate-quarries. The workings date from about 1630, and extend to a depth of 220 feet below sea-level.

Easel (Dut. *ezel*, 'an ass,' cf. *clothes-horse*), the wooden frame on which painters place pictures while at work upon them.

Easement. In English law, a person may have rights of several kinds in the land of another. He may have the right to take or receive part of the produce or profit of the land; this right is

Common Earwig:

a and b, young stages; c, adult with wings expanded.

called a Profit. He may have the right to use his neighbour's land for his own convenience (as e.g. by making use of a road over it, by laying out nets to dry upon it, &c.), and this kind of right is called a Positive Easement. Again, he may have the right to prevent his neighbour from making an inconvenient use of the land—e.g. the right to prevent him from erecting buildings which obstruct the light—and this kind of right is called a Negative Easement. An easement can only be enjoyed by an owner and occupier of land; the property in respect of which the right is enjoyed is called the dominant tenement; the property over which it is enjoyed is called the servient tenement. Profits and easements are both regarded as rights of property in land; they are 'incorporeal hereditaments.' Easements are of many kinds; they include rights of way, rights to water, light, and air, rights to support from neighbouring land, rights to transmit the vapours and noises of an offensive trade, &c. They are acquired by express or implied grant (as when a house is conveyed together with a right of way), and also by prescription and custom; they may be extinguished by express or implied release and in other ways. The period of enjoyment which gives a good title is for an easement 20 years and for a profit 40. The American law on this subject is in its general principles the same as the English. In Roman and Scots law, profits and easements are both included under the title of Servitudes (q.v.).

East (O.E. *east*, cognate with Lat. *aurora*, 'dawn', Gr. *aurion*, 'morning'; compare also *Easter*, *Austria*) is, vaguely speaking, that quarter of the horizon where the sun rises, or which a person with his face to the south has on his left hand. It is only at the equinoxes that the sun rises exactly in the east point. A line at right angles to the meridian of a place points exactly east and west. From very early times, the east has been invested with a certain sacred character, or at least held in higher respect than other points of the compass. It was the practice of many ancient pagans to fix their altar in the eastern part of their temples, so that they might sacrifice towards the rising sun (see *SUN-WORSHIP*). Contrariwise, in the temple of Jerusalem the Holy of Holies was at the western end; and hence it was customary for Jews in other parts of the world to turn towards the west in prayer. But the custom of praying towards the east was adopted by the early Christian church from at least the 2d century, as a symbol of Christ as the 'Sun of righteousness,' the 'Dayspring from on high,' and the 'Morning Star,' a reason assigned by Clement of Alexandria, who died about 220 (*Stromata*, vii.), and who is followed by Tertullian and St Athanasius. Accordingly, in the ancient baptismal forms, the candidate was made to face westward when renouncing the devil and his works, but then to turn round to the east in order to make his profession of faith in Christ; while, for a similar reason, the sanctuaries of Christian churches, wherein the altar stood, were built at the east end, a custom enjoined as early as the compilation of the *Apostolical Constitutions* (ii. 57). It was said, further, that Christ had been placed in the tomb with his feet towards the east, and that at the day of judgment he should come from the eastward in the heavens. From these various circumstances (see *ORIENTATION*) bowing to the east on uttering the name of Jesus, and burying with the feet to the east, were also introduced as customs in the church. The churches of the city of Rome do not conform generally to the principle of orientation, probably because some of the more important among them were originally secular buildings of the imperial times, and served as

examples for subsequent erections. It is a curious instance of the inveteracy of popular custom, that in Scotland, where everything that savoured of ancient usage was set aside as popish by the reformers, the practice of burying with the feet to the east was maintained in the old churchyards, nor was it uncommon to set down churches with a scrupulous regard to east and west. In modern cemeteries in England, Scotland, and America, no attention appears to be paid to the old preference for burying with the feet to the east, the nature of the ground alone being considered in the disposition of graves.

The eastward position of the officiating priest at the prayer of consecration of the eucharist has been matter of much controversy in the Church of England. The High Church party interpret the rubric (1552) as allowing or enjoining that position (the consequence of which is that the celebrant has his back to the congregation); but the legality of the position, decided against in the *Purchas* case (1870), was again called in question in that of the Bishop of Lincoln (1889).

Eastbourne, a favourite Sussex watering-place, especially for the wealthier classes, in the Rape of Pevensey, nearly midway between Brighton and Hastings, and 66 miles S. of London. Roman remains bear witness to its antiquity, but nothing is known of its ancient history. In the Domesday Book it is called *Borne* (after the burn or stream which still flows there), and is stated to have been held by the Confessor at forty-six hides. The Conqueror bestowed it upon the Earl of Morton, and it subsequently passed through the Barons of Badlesmere and De Roos to the Manners family, and thence to Selwyns, Gildridges, and Burtons, from whom the Duke of Devonshire and C. Davies Gilbert inherited the manorial rights. The fine 12th-century church clearly belonged to a much more important place than the four groups of houses and cottages which, at a late period, constituted the fishing-hamlets of East Borne, South-Borne, Meads, and Sea-Houses. The last third of the 19th century witnessed the growth of the modern watering-place, which now challenges comparison, in respect of its attractions to visitors and advantages to residents, with any of its south-coast rivals. Its air is singularly healthy, and on the hillside bracing. The death-rate is low. The close vicinity of the bold promontory of Beachy Head and the 'front-hills' of the South Downs affords unusual facilities for exercise, and the country is regularly hunted. The sea-front, defended by a redoubt and other obsolete fortifications, boasts a parade three miles long, laid out in spacious terraces in three tiers, bordered by creeping plants. The streets are broad and lined with trees. Devonshire Park has a winter garden and a concert hall. There are admirable golf links. Much of the improvement is due to the seventh Duke of Devonshire, but the town took an enterprising share, for which loans were incurred since 1864 to the amount of £173,000. The handsome town-hall was opened in 1886, the Free Library in 1896. The acreage of Eastbourne borough is 6474; the population in 1821 was but 2007; in 1861, 5795; in 1891, 34,977; in 1911, 52,542; and in 1921, 62,030. Eastbourne was incorporated a borough in 1883. By an Act of Parliament of 1910 Eastbourne became a county borough in 1911, with a greatly extended area, a portion of Willingdon parish being absorbed.

East Cape, the name of the south-eastern extremity of New Guinea, in Goschen Strait, and of the most easterly headlands of Madagascar, the North Island of New Zealand, and Siberia. The last, on Behring Strait, and in 169° 38' W. long., is the easternmost extremity of Asia, and is a bold, rocky promontory of syenite, almost cut off from the mainland by swamps and lakes.

East Chicago, a city and port of Indiana, on Lake Michigan, practically part of Chicago, has iron and steel manufactures; pop. 36,000.

Easter (Ger. *ostern*, Fr. *pâques*, Scot. *pasch*, from Gr. *pascha*, 'the passover'), the festival of the resurrection of Jesus Christ, derives probably its name from Eastre, an English spring (and dawn) goddess, whose festival was kept at the vernal equinox. In the ancient church, the celebration of Easter lasted an octave (eight days). After the 11th century, however, it was limited to three, and in later times, generally to two days. It was formerly the favourite time for performing the rite of baptism. The courts of justice were closed, and alms dispensed to the poor and needy, who were even feasted in the churches—a custom which led to much disorder. Slaves also received their freedom at that season; and as the austerities of Lent were over, the people gave themselves up to enjoyment; hence the day was called the 'Sunday of joy' (*Dominica gaudii*). In the East it is still known as the 'Bright Day,' and in Bohemia it is designated the 'Great Night.' To the popular sports and dances were added farcical exhibitions, in which even the clergy joined in some places, reciting from the pulpits stories and legends, with a view to stir the hearers to laughter (*risus paschalis*). Against this indecency the Reformers of the 16th century loudly and successfully raised their voices. During the whole week before Easter—i.e. in the interval between Palm Sunday and the beginning of the Easter festival—daily services were held (see HOLY WEEK, and GOOD FRIDAY).

On Easter Day, the people saluted each other with the Easter kiss, and the exclamation *Surrexit* ('He is risen'); to which the reply was *Vere surrexit* ('He is risen indeed')—a custom still retained in the Greek Church. Thus, in Russia, at the time of salutation, red eggs are exchanged, and cage-birds are let loose, as emblematical of that liberty which is consecrated by the Easter solemnities. The chief solemnity has always consisted of the celebration of the Lord's Supper; and Easter is the one time in the year at which, by the Fourth Lateran Council, Roman Catholics must communicate.

The proper time for the celebration of Easter has occasioned no little controversy. In the 2d century a dispute arose on this point between the Eastern and Western Churches. The great mass of the Eastern Christians celebrated Easter on the 14th day of the first Jewish month or moon, considering it to be equivalent to the Jewish Passover. The Western churches kept it on the Sunday after the 14th day, holding that it was the commemoration of the resurrection of Jesus. The Council of Nice (325 A.D.) decided in favour of the Western usage, branding the Eastern usage with the name of the 'quartodeciman' heresy. This, however, only settled the point that Easter was to be held, not upon a certain day of the month or moon, but on a Sunday. The proper astronomical cycle for calculating the occurrence of the Easter moon was not determined by this council. It appears, however, that the Metonic cycle was already in use in the West for this purpose; though great discrepancies obtained as late as 541; and the British churches clung closely to an old cycle of

eighty-four years, originally adopted from the Roman Church. The controversy as to the celebration of Easter in England was practically authoritatively settled by the adoption of the Roman usage at the Council of Whitby in 664, Wilfrid being the spokesman of the victorious party, Colman the defender of the traditional Celtic usage. It was on the metonic cycle that the Gregorian Calendar, introduced in 1582, was arranged. The method on which this calendar is constructed is too complex for description here. An elaborate account of the whole matter was published by Professor De Morgan in the *Companion to the British Almanac* in 1845. The time of Easter, being the most ancient and important of all the movable feasts of the Christian church, determines all the rest. It was debated, at the time of the introduction of the Gregorian Calendar, whether Easter should continue to be movable, or whether a fixed Sunday, after the 21st of March, should not be adopted. It was deference to ancient custom that led the ecclesiastical authorities to adhere to the method of determination by the moon. It must be remembered, however, that it is not the actual moon in the heavens, nor even the mean moon of astronomers, that regulates the time of Easter, but an altogether imaginary moon, whose periods are so contrived that the new (calendar) moon nearly always follows the real moon (sometimes by two days). The effect of this is, that the 14th of the calendar moon—which had, from the times of Moses, been considered 'full moon' for ecclesiastical purposes—falls generally on the 15th or 16th of the real moon, and thus as a rule after the real full moon, which is generally on the 14th or 15th day. With this explanation, then, of what is meant by 'full moon'—viz. that it is the 14th day of the calendar moon—the rule is, that Easter Day is always the first Sunday after the paschal full moon—i.e. the full moon which happens upon or next after the 21st of March (the beginning of the ecclesiastical year); and if the full moon happens upon a Sunday, Easter Day is the Sunday after. For any given year, the day on which the paschal full moon falls, and then Easter Day, are found by the following table and rule:

Days of the Month	Dom Letter	Golden Number	Days of the Month	Dom Letter	Golden Number
March 21	C	14	April 9	A	15
" 22	D	3	" 10	B	4
" 23	E	"	" 11	C	"
" 24	F	11	" 12	D	12
" 25	G	"	" 13	E	1
" 26	A	19	" 14	F	"
" 27	B	8	" 15	G	9
" 28	C	"	" 16	A	"
" 29	D	16	" 17	B	17
" 30	E	5	" 18	C	6
" 31	F	"	" 19	D	"
April 1	G	13	" 20	E	"
" 2	A	2	" 21	F	"
" 3	B	"	" 22	G	"
" 4	C	10	" 23	A	"
" 5	D	"	" 24	B	"
" 6	E	18	" 25	C	"
" 7	F	7			
" 8	G	"			

First ascertain the Dominical Letter (q.v.)—taking the second, where there are two—and the Golden Number (q.v.); look for the golden number in the third column of the table, and opposite to it stands the day of the full moon; then look for the dominical letter, next after the day of full moon, and the day standing opposite the dominical letter is Easter Day. It sometimes happens that Easter Day, as thus determined, is different from what it would be if by 'full moon' were understood the astronomical full moon. Thus, in 1818 Easter Day, by the calendar, fell, and was celebrated on the 22d of March, the earliest

possible day, although the full moon was on that day; and in 1845 it again fell on the day of the actual full moon (the 23d March).

One object in arranging the calendar moon was that Easter might never fall on the same day as the Jewish Passover. They did occur together, however, in 1805 on the 14th of April; in 1825 on the 3d of April; in 1903 on the 12th of April; in 1923 on the 1st of April; and will do so again in 1927 on the 17th April; and in 1981 on the 19th April. The Jewish festival usually occurs in Passion-week, and never before the 26th of March or after the 25th of April (new style). On the other hand, the Christian festival is never before the 22d of March, or after the 25th of April. In 1761 and 1818 Easter fell on the 22d of March, a date which will not recur before the end of the 20th century. In 1913 it fell on the 23d of March, as it did in 1845 and 1856. The latest Easters in the 19th and the 20th century occur in 1886 and 1943 on the 25th of April. In 1848 Easter fell on the 23d of April; and in 1859, on the 24th of April. A fixed date for Easter is among the ends that have been proposed in various plans for the reform of the calendar. A bill for this purpose, for instance, was introduced in the British parliament in 1921. In 1923 a congress of the Orthodox Churches at Constantinople adopted the Gregorian calendar, and passed a resolution in favour of keeping Easter upon the first Sunday after the first full moon after the equinox—full moon and equinox both being reckoned by astronomical tables. Many Anglicans favour the second Sunday in April.

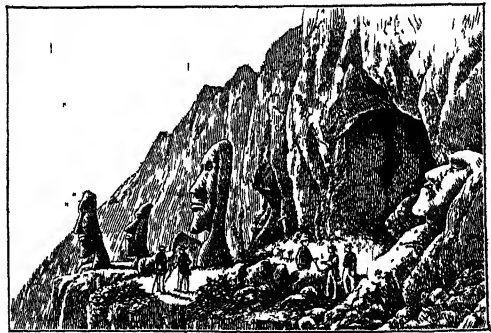

Popular Observances.—Many of the popular observances connected with Easter are clearly of pagan origin, and traceable to the feast of the goddess 'Eostre,' the Old English name of April having been Easter-month, which still survives in the German Ostermonath. The worship of this deity, introduced into England by the Saxons, continued to be celebrated in many parts in the north of Germany down to the beginning of the 19th century by the kindling of bonfires and numerous other rites (see BELTANE). Like the May observances of England, it was especially a festival of joy. With her usual policy, the church endeavoured to give a Christian significance to such of the rites as could not be rooted out; and in this case the conversion was particularly easy. Joy at the rising of the natural sun, and at the awaking of nature from the death of winter, became joy at the rising of the Sun of Righteousness—at the resurrection of Christ from the grave. The bonfires can be traced in the great 'paschal tapers,' or 'Easter candles,' sometimes weighing 300 lb., with which the churches were lighted on Easter Eve. In the ancient church disbursements of St Mary-at-Hill, in the city of London, there is even an entry 'for a quarter of coles for the shallowed fire on Easter Eve, 6d.'

The Easter offerings or dues are 'customary sums' which from time immemorial have been paid, and are recoverable as small tithes before the justices of the peace.

One of the most popular features of Easter was the Pasch or Easter egg, an old emblem of the resurrection; although the egg, as symbolical of renewed life, may be traced back to a very primitive period. De Gebelin has connected it with the ancient Egyptians, Persians, Greeks, and Romans; and Schwartz says it was customary among the Parsees to distribute red eggs at their spring festival. In Germany, instead of the Easter egg, is presented an emblematical print, in which three hens are holding a basket wherein are three eggs; whereas in Vienna the Easter egg is composed of silver, mother-of-pearl, or bronze, and filled with

knuck-knacks of some kind. Formerly in this country the Easter egg was solemnly blessed by the priest, and being elaborately coloured, was often kept as an amulet. Most of the old customs and superstitions associated with the Easter festival have fallen into disuse, but as a holiday season its popularity is not likely to decrease. Easter cards are greetings like Christmas (q.v.) cards. For the Easter term, see TERM.

Easter Island, a lonely Pacific islet in 27° 8' S. lat., and 109° 24' W. long. Discovered by Roggeveen on Easter Day 1722, and visited in 1773 by Captain Cook, it is 47 sq. m. in area; is entirely volcanic, with many extinct craters rising more than 1000 feet; and is fertile, but badly off for water. Sheep and cattle grazing was started by a French house in Tahiti, after the departure in 1875 of the missionaries, with 300 natives, for the Gambian Archipelago, 500 having been shipped to Tahiti four years earlier. The natives still left are fair Polynesians, with some Melanesian characteristics; since 1860 they have dwindled from 3000 to 220, as well from polyandry as from emigration. They have little to say as to the origin of the picturesque remains that

Stone Statues on the side of the Volcano Ronororaka, Easter Island.

have made Easter Island famous. These include over 500 rude stone statues or busts, varying from 3 feet high to 70. There are besides 100 stone houses, with painted interiors and (undeciphered) incised tablets. Most of the natives were carried off in 1863 by the Peruvians to work guano. The island has been, since 1888, a Chilean possession. See Thomson, *Report to the U.S. National Museum* (1892); Churchill, *Easter Island* (1912); Mrs. Routledge, *Mystery of Easter Island* (1919); J. M. Brown, *The Riddle of the Pacific* (1924).

Eastern Empire. See BYZANTINE EMPIRE.

Eastern Question is the name given primarily to the problem what is to become of the east of Europe—specifically, the area of Europe now or lately under the authority of the Turks. In the 18th century the western European powers were jealous of Russia and Austria in their wars with Turkey, and sympathised more or less openly with the Turks. England supported Turkey against Bonaparte in Egypt in 1798. The question was from time to time raised by Russia's claim to be the protector of the Christian populations in the Turkish area, which till 1878 comprised more or less directly Rumanians, Serbs, Greeks (of Macedonia, &c.), and Bulgarians; as also by Russia's aim to be regarded and treated as the heir-in-chief of the 'sick man.' The question became acute in 1854, and the Crimean War (q.v.) was an attempt to solve or shelve it, France supporting England in the

struggle to maintain the *status quo*. The Russo-Turkish war in 1877-78, the Berlin Congress of 1878, the Italo-Turkish war, the Balkan wars of 1912-13, the various conferences and treaties connected with them, were chapters in the history of the question. Sometimes the question has been practically how to prevent the undue aggrandisement of Russia, especially as against England; and Asia Minor, Persia, Turkestan, Afghanistan, even Egypt and India, have come within the sphere of this complicated and formidable question, and not merely the Balkan Peninsula. At last Russia's designs upon Constantinople, Germany's 'Drang nach Osten,' France's ambitions in Syria, Italy's in Anatolia, Britain's solicitude about India, Armenian, Arab, Egyptian, Indian, and Balkan nationalism, were merged in the greater complex of the European war and its political sequelæ.—Of late 'the Far-Eastern Question' includes China and Japan, and the rivalries of European powers in these regions.

Eastham, a township and parish of Cheshire, on the Mersey, $6\frac{1}{2}$ miles SE. of Birkenhead, near the seaward end of the Manchester Ship Canal.

East India Army. When the East India Company (q.v.) first sent factors or agents to India, an army was not thought of. Military forces arose out of the exigencies of the times, and at first included adventurers, convicts, and deserters from European armies. Gradually organisation was introduced, and as the power of the Company increased, natives entered the service, until at length most of the troops were Hindus or Mohammedans, drilled by non-commissioned officers sent out from England. A few regiments were raised in England, a much larger number in India; but all alike were officered by the Company's English officers. Before the outbreak of the Mutiny the forces in the pay of the Company comprised about 280,000 men, including 180,000 native regulars, and 60,000 native irregular horse; and these troops formed three distinct armies, one for each presidency, and each with its own commander-in-chief, although the commander-in-chief in Bengal exercised authority over the other two, an arrangement maintained under the later organisation till 1893. To what extent this fine force melted away during 1857 and the two following years is described under INDIA. Under the Act of 1858 the army also was transferred to the crown, the government, to prevent a threatened disturbance, allowing such as chose to retire. As the Sikhs had behaved well, most of the regiments from the Punjab were retained, as well as most of the native regiments in the Bombay and Madras presidencies; but it was not deemed expedient to restore the native regiments of Bengal proper which had proved so treacherous.

The strength of the British forces *lent* to India is annually fixed in the army estimates laid before parliament, and comprises about 80,000 officers and men. The Indian army numbers about 160,000, of whom the infantry exceed 120,000, and the cavalry amount to about 25,000, so that the total military force of India may be stated at 220,000 (see ARMY). These figures are exclusive of the armies maintained by the feudatory or independent states; their total strength is estimated at 350,000 men. During the Eastern crisis a force of native Indian troops was sent to Malta; and in the Egyptian war of 1882 and the European war of 1914 Indian troops fought with distinction along with their English fellow subjects.

East India Company. The establishment of an East Indian trade dates from the time when

the Portuguese navigator, Vasco da Gama, having effected the eastern passage to India by doubling the Cape of Good Hope, cast anchor off the city of Calicut on the 20th May 1498. The Portuguese, however, never actually founded a trading company; their admirals were the king's officers, whose efforts were directed rather towards the conquest and conversion of the eastern races than to mere commerce, except as a royal monopoly. Nevertheless they were supreme in the seas they had opened from 1500 to 1600, and dispensed the treasures of all the islands of the East, from Goa to Celebes, and as far northward as Japan; for it was on the islands that the Europeans, one and all, first gained a permanent footing. In the next century their place was rapidly taken by the Dutch, whose first vessel had rounded the Cape only in 1596, and whose East India Company was founded in 1602. The earliest incorporated East India Company was the English, to which Queen Elizabeth granted a charter on the last day of the 16th century (31st December 1600), under the title of 'The Governor and Company of Merchants of London trading to the East Indies.' Two later companies, after a short period of competition, united with the original association; and in 1709 its last and most formidable rival, the English Company (1698), was amalgamated with the London Company, under the style of 'The United Company of Merchants of England trading to the East Indies.' About 1624 the English were compelled by the Dutch to withdraw nearly all their factories from the archipelago, and, shut out from the trade of the islands, they began to found settlements on the coast of the Indian peninsula. The nucleus of Madras dates from 1639; Bombay came to the Company in 1668; Calcutta was founded in 1686; finally, in 1689 the Company passed the resolution to acquire territorial sway, to 'make us a nation in India,' which was to change its factors and clerks into governors and conquerors. The old Company's charter, granting exclusive trading rights in the Indian and Pacific oceans, had been renewed from time to time, with various modifications, though not without much contention and difficulty; and these exclusive privileges were extended, in consideration of sundry loans to the government aggregating £3,200,000, to the united Company, whose constitution thus established was maintained with little alteration as long as the Company existed. Every shareholder who held £500 of the Company's stock became a member of the Court of Proprietors, which annually chose twenty-four to form a Court of Directors from those of their number who held not less than £2000 of stock. Six of the directors went out of office every year; they retired in rotation, so that each had four years of office. It was a general custom with the proprietors to elect the same persons as directors over and over again. Theoretically, the constitution of the Company was very democratic, but practically the affairs were in the hands of the directors; for the proprietors took little other interest than in receiving their half-yearly dividends. The proprietors had from one to four votes each, according to the amount of stock held by them. The Board of Control, of later formation (1784), bore relation to the governmental affairs of India.

Properly speaking, the Company were only merchants: sending out bullion, lead, quicksilver, woollens, hardware, and other goods to India; and bringing home calicoes, silk, diamonds, tea, porcelain, pepper, drugs, saltpetre, &c. from thence. Not merely with India, but with China and other parts of the East, the trade was monopolised by the Company; and hence arose their great trade in China tea, porcelain, and silk. Until Clive's day, however, paltry and insufficient salaries were paid

to the servants of 'John Company,' who were permitted to supplement their income by every means in their power—to 'shake the pagoda tree.' By degrees avarice and ambition led the Company, or their agents in India, to take part in the quarrels among the native princes; this gave them power and influence at the native courts, and hence arose the acquisition of sovereign powers over vast regions. India thus became valued by the Company not only as commercially profitable, but as affording to the kinsfolk and friends of the directors opportunities of making vast fortunes by political or military enterprises. It is not the purpose of the present article to trace the political affairs of the Company, or the rise of a British empire in India; that will be done under INDIA.

In 1744 the Company obtained a renewal of their charter till 1780, but not without a loan of £1,000,000 to government; for the monopoly was distasteful to the nation at large. France, too, had an East India Company (six had been established between 1604 and 1719), and the struggles between the two companies for power in the southern part of India led to constant warfare between them during the 18th century. Other loans to government were the means of obtaining further renewals of the charter in later years. In 1833 the legislature took away all the trading privileges of the Company. The dividends to proprietors of East India stock were thenceforward to be paid out of taxes imposed by the Company on the people of India, in such provinces as were under British dominion. From that year the Company's powers became anomalous; the Company could not trade, and could not govern without the sanction and continued interference of the imperial government. The wars in India since that year have been waged by Britain as a nation, rather than by the Company; and Britain practically, though not nominally, became responsible for the enormous cost of those wars. In 1853 the charter was renewed for the last time, for an indefinite term of years, but with a further lessening of the power of the Company, and an increase of that of the crown; patronage also was abolished.

After the Mutiny the Company was forced, in spite of a strenuous resistance, to cede its powers in 1858 to the crown, under an act for the better government of India. Most of the distinguished men, military and political, till then in the Company's service, accepted office under the crown, to assist the government by their general knowledge of Indian affairs. These affairs are now managed by a Secretary of State for India. The East India House (1726) was demolished in 1862; and Haileybury (q.v.), the East India college since 1806, was closed in 1853.

See Sir John W. Kaye, *The Administration of the East India Company* (1853); J. T. Wheeler, *India under British Rule* (1886); *Davens' *Records of the E.I.C.* (1896 et seq.); Beckles Willson, *Ledger and Sword* (1903); and other books cited under INDIA.

East Indies, as distinguished from *West Indies*, include not merely the two great peninsulas of Southern Asia, but likewise all the adjacent islands from the delta of the Indus to the northern extremity of the Philippines (see INDIA). For the Dutch East Indies, called sometimes *Insulende*, see HOLLAND.

Eastlake, SIR CHARLES LOCK, President of the Royal Academy, was born at Plymouth in 1793, and studied in London and Paris. When the *Bellerophon*, with Napoleon on board, appeared in the port of Plymouth, Eastlake profited by the opportunity, and produced, from a number of rapid sketches taken in a shore-boat, two full-length portraits of the emperor. From 1816 to 1830 he

made his home in Rome, where he executed the 'banditti' pictures that first attracted attention to him in England. In this period also he exhibited 'Isidas the Spatan,' 'Pilgrims in sight of Rome,' and 'Byron's Dream.' In 1827 he was elected an Associate, and in 1830 a full member of the Royal Academy. In 1839 appeared 'Christ blessing little Children,' and in 1841 his great work, 'Christ weeping over Jerusalem,' now in the National Gallery. In 1850 he was elected President of the Royal Academy, and received the honour of knighthood. In 1855 he was appointed, Director of the National Gallery, in which capacity his services were as valuable as they were unsparingly given; and it was during one of his journeys in search of pictures for the national collection that he died at Pisa, 14th December 1865. Eastlake became an eminent art authority, and published *Materials for the History of Oil Painting* (1847); translated Goethe's *Theory of Colours* (1840); and prepared valuable papers, collected in *Contributions to the Literature of the Fine Arts* (1848 and 1870). To the second series a Memoir is prefixed by Lady Eastlake (Elizabeth Rigby, of Norwich, 1810-93), the authoress of *Letters from the Baltic*, and the venomous reviewer of *Jane Eyre* in the *Quarterly*. (See her own *Journals*, 1896.) Eastlake was F.R.S., D.C.L. of Oxford, and a Chevalier of the Legion of Honour.

East Liverpool, a city of Ohio, on the Ohio River, 32 miles WNW. of Pittsburg, with extensive potteries, steel and rubber works; pop. 21,000.

East London, a South African seaport, at the mouth of the Buffalo River, 36 miles SE. of King Williamstown, and 700 miles E. of Capetown, with a large export and import trade. It is the terminus of a railway to the interior. Harbour works have been erected to protect the formerly exposed anchorage. Pop. 30,000. The division of East London, with an area of 1225 sq. m., was formed from part of British Kaffraria in 1866.

East Lothian. See HADDINGTONSHIRE, LOTHIAN.

East Main, the name formerly given to a region of Canada, also known for a time as Ungava. It occupies all the peninsula of Labrador (q.v.) except the southern portion, from which it is divided by the East Main and Hamilton rivers, and the eastern coast strip belonging to the Newfoundland territory of Labrador (see map at article CANADA). Its area is estimated at about 456,000 sq. m. It was transferred in 1912 from the North-West Provinces to Quebec.

Easton, capital of Northampton county, Pennsylvania, stands in the fork between the Delaware and Lehigh rivers, 52 miles N. of Philadelphia. A number of railways and canals meet here, and the town has considerable trade, and manufactures silks, wire, flour, &c. Easton is the seat of Lafayette (Presbyterian) College (1832). Pop. 34,000.

East Orange, a city of Essex county, New Jersey, inhabited by New York and Newark business men, manufactures electrical apparatus; pop. 51,000.

East Providence, a town of Rhode Island, separated from Providence by the Blackstone River; pop. 22,000.

East River, the strait between Long Island Sound and New York Harbour, separating the New York boroughs of Brooklyn and Queens from Manhattan and the Bronx. It is about 10 miles long, and $\frac{1}{2}$ mile wide at the narrowest point, and is navigable by the largest ships.

East Saginaw (now 'Saginaw East Side'), the former name of that portion of Saginaw

lying east of the Saginaw River, incorporated with Saginaw (q.v.) in 1890.

East St Louis, a city of Illinois, connected with St Louis, Missouri, by a grand steel bridge over the Mississippi. It is an important railway terminus, contains Catholic and Baptist colleges, manufactures iron goods, soda, and glass, and has huge stockyards. Pop. (1890) 15,190; (1900) 29,655; (1910) 58,547; (1920) 66,767.

Eastwick, EDWARD BACKHOUSE, English Orientalist and diplomatist, was born at Warfield, in Berkshire, on 13th March 1814, and educated at the Charterhouse and Oxford. Proceeding to India as a cadet of the East India Company in 1836, he was soon chosen to fill political offices in Kathiawar and Sind. From 1845 to 1859 he was professor of Hindustani at Haileybury College, and in the latter year was appointed assistant political secretary in the India Office. He then spent three years (1860-63) as secretary of legation in Persia. He died at Ventnor, Isle of Wight, 16th July 1883. His best works are translations from the Persian (Saadi's *Gulistan*, 1852; *Arrival of the Parsees in India*, 1845; *Life of Zoroaster*, 1843; and *Anwar-i Suhaili*, 1854); a *Hindustani Grammar* (1847; 2d ed. 1858); *Journal of a Diplomat in Persia* (1864); and *Kausar-nama-i-Hand or Lay of the Empress* (1878-82). He also translated into English Bopp's *Comparative Grammar* (1856) and Schiller's *Revolt of the Netherlands* (1844).

Eau Claire, capital of Eau Claire county, Wisconsin, at the mouth of the Eau Claire River, and at the head of navigation on the Chippewa River, 183 miles NW. of Madison by rail. It has a vast trade in lumber, and contains numerous saw-mills, besides planing-mills, grist-mills, foundries, and machine-shops. Pop. (1870) 2293; (1880) 10,119; (1900) 17,517; (1920) 20,906.

Eau Cr  ole, a very fine liqueur, made in Martinique, by distilling the flowers of the Mam-mee Apple (*Mammea americana*) with spirit of wine.

Eau de Cologne, a celebrated perfume, the reputed inventor of which is Johann Maria Farina (1685-1766), a native of Piedmont, who settled in Cologne in 1709, though his claim to be the inventor is not undisputed. The secret of the process of its manufacture is claimed by from thirty to forty firms, bearing the name of Farina, now existing in Cologne. The recipe is said to be twelve drops of each of the essential oils neroli, citron, bergamot, orange, and rosemary, along with one drachm of Malabar cardamoms and one gallon of rectified spirit. The whole is distilled together, and the condensed liquid constitutes Eau de Cologne. In Great Britain, where chemists and others make an article little, if at all, inferior to the imported one, the oils are usually mixed with a highly purified spirit, and the subsequent distillation dispensed with.

Eau de Vie. See BRANDY.

Eaux Bonnes, a watering-place of France, in the department of Basses-Pyr  n  es, is situated in a narrow gorge of the Pyrenees, at an altitude of 2454 feet, and 29 miles S. of Pau. Pop. 500, with 6000 to 10,000 visitors in the season (July to August). The springs, both hot and cold, the former with a temperature ranging from 53   to 91   F., contain sulphur and sodium; the water is used for disorders of the chest and respiratory organs.

Eaux Chaudes, a watering-place of France, 27 miles S. by W. of Pau, situated in a narrow Pyrenean valley, 2215 feet above sea-level. Its waters, which are sulphurous, and range in temperature from 50   to 93   F., are useful in cases of catarrh and rheumatism, also for skin-diseases.

Eavesdrip, an ancient Saxon custom, corresponding to the well-known urban servitude of the Romans called *stillicidium* (*stillicidium*), where a proprietor was not allowed to build to the extremity of his estate, but must leave a space regulated by the charter by which the property was held, so as not to throw the eaves-drop on the land of his neighbour.

Eaves-droppers 'are such as listen under walls or windows, or the eaves of houses, to hearken after discourse, and thereupon to frame slanderous or mischievous tales' (Blackstone). Such persons are, by the law of England, regarded as common nuisances, and are punishable by fine.

Ebal. See GERIZIM.

Ebb and Flow. See TIDES.

Ebbfleet. See RAMSGATE.

Ebbw Vale, an urban district in the north-west corner of Monmouthshire, 21 miles NNW. of Newport, lies in the middle of a rich iron and coal district. Pop. 35,000.

Ebenace  , an order of dicotyledonous trees and shrubs allied to Sapotace  . About 250 species are known, mostly tropical, of which many furnish hard and durable timber (see EBONY); several are natives of the United States. The fruits are often edible. See DATE PLUM.

Ebenezer (Heb. 'stone of help'), a monument raised by Samuel after his victory over the Philistines, was assumed by early Christian hermits to be at a place now called Deiraban, near the western border of Judah. But the site is not really known.

Eberhard, AUGUST GOTTLIEB, a well-known German writer, was born at Belzig in 1769, studied first theology at Leipzig, then devoted himself to a busy life as a man of letters at Halle, Hamburg, and lastly at Dresden, where he died, 13th May 1845. Eberhard's literary reputation depends upon his *Hannchen und die Kuchlein* (1822), an idyl which has been translated into many languages, and is still popular, and his long poem in hexameters, *Der Erste Mensch und die Erde* (1828). His collected works fill 20 vols. (1830-31).

Eberhard, JOHANN AUGUST, philosophical writer, was born at Halberstadt, 31st August 1739; studied theology at Halle, and after some years preaching in Berlin and Charlottenburg, became professor of Philosophy at Halle in 1778. He died 6th January 1809. Eberhard's first work was his *Neue Apologie des Sokrates* (1772), an able and outspoken book, in which the rights of common sense are vindicated against the assumptions of a narrow theology. Among his numerous books may be mentioned, *Sittenlehre der Vernunft* (1781), and *Versuch einer allgemeinen Deutschen Synonymik* (6 vols. 1795-1802), a work which was enriched and improved by Maas (12 vols. 1818-21), and again by Gruber (6 vols. 1826-30). Towards the close of his life, Eberhard vainly strove to controvert the metaphysics of Kant by vindicating the earlier theories of Leibniz and Wolf.

Ebers, GEORG MORITZ, a distinguished Egyptologist and novelist, was born 1st March 1837, at Berlin, was educated at Froebel's school, and studied law at G  ttingen. He afterwards devoted himself to the study of Egyptology at Berlin, in pursuit of which he visited the chief museums of Europe. He established himself in 1865 as a lecturer at Jena, where in 1868 he was made professor. Next year he made a long journey to the East, and in 1870 was called to Leipzig as professor of Egyptology. His visit to Egypt had resulted in the discovery of the celebrated hieratic medical *Papyrus Ebers*, which he published in 1875. His most important work besides this is *Aegypten und*

die Bucher Moses (vol. i., all published, 1868). His interesting and picturesque, if slight, *Durch Gosen zum Sinai*, and *Aegypten in Bild und Wort*, have been translated into English. In 1876 he became paralysed, and necessary inaction induced him to continue the writing of historical novels, begun in 1864 with his *Egyptian Princess*, in which a good plot is made the foundation for much Egyptological learning. Ill-health compelled him to resign his post, and he lived mainly in Munich. He died 7th August 1898. See his *Story of my Life* (trans. 1893), and a work by Gosche (1887).

Eberswalde, an industrial town of Prussia, 28 miles N.E. of Berlin by rail, with manufactures of nails, felt, &c.; pop. 27,000.

Ebert, FRIEDRICH (1870-1925), first president of the German republic, was born in Heidelberg, a tailor's son. He became a saddler, a social democrat journalist, in 1912 a member of the Reichstag, and in 1913 chairman of his party. In the revolution of 1918 he was a majority socialist leader. He was elected president by the National Assembly in February 1919. In 1922 his term was extended to 1925 by agreement of parties in the Reichstag.

Ebert, KARL EGON, a Bohemian poet, was born at Prague in 1801, was for many years a librarian at Donaueschingen, and died at Prague, 24th October 1882. His poems include lyrics, epics, tragedies, and dramas from Bohemian history, and collected fill 7 volumes (Prague, 1877).

Ebionites (Heb. *ebion*, 'poor'), a term applied probably at the beginning of the Christian church to all Christians, afterwards the general name by which all Jewish Christians who remained outside the Catholic Church were designated after the apostolic age down to the time of Jerome. The name was, doubtless, derived in part from the poverty of the early community at Jerusalem, partly from the close connection between poverty and piety dwelt on in the Psalms and Prophets and by Christ himself. A distinction between the Ebionites and Nazarenes, indicated by Justin and Origen, and first clearly made by Jerome, has been carefully drawn out by Bishop Lightfoot in the dissertation on 'St Paul and the Three' in his commentary on Galatians (6th ed. Lond. 1880); but Harnack holds that the Judaizing Christians, though of many shades, were not divided into two distinct parties, and were not originally distinguished from the 'Great Church' by differences of 'doctrine,' but only in the forms of their religious life, while they had the following points of controversy among themselves: (1) Whether the observance of the law was a necessary condition of the reception of the Messianic salvation; (2) whether it was to be insisted on in the case of Christians born in heathenism, before they could recognise them as Christians; (3) whether, and in how far, they ought to hold fellowship with Gentile Christians, who did not keep the law; (4) whether Paul had been an elect servant of God, or an intruder hateful to God; (5) whether Jesus was a son of Joseph, or miraculously conceived by the power of the Holy Ghost. Their Gospel was some form of that known as the *Gospel to the Hebrews*. On the foundation of earlier Ebionite writings arose the Pseudo-Clementines, which must be used with great caution as evidence of the tendencies and inner history of syncretistic Jewish Christianity, as it is not till the 3d century that acquaintance with them is clearly traceable in the literature of the church. Hippolytus and Origen (in Eusebius) describe a kindred Syrian variety of Jewish Christians, who from their sacred book, supposed to have fallen from heaven, called themselves *el kesi* ('hidden power'), and are hence distinguished as *Elkesaites*. In the time of Epiphanius, who

calls them 'Ebionites,' they were in large numbers in the Dead Sea district. To them Jesus was merely a prophet, whose teaching had been completed by a succeeding prophet, and by a new revelation, which seems to have been a confused mixture of Christian, Essene, and heathen elements. Their characteristic tenets reappear in Mohammedanism. See Harnack's *History of Dogma*, vol. i.; Schurer's *Jewish People*; and the article in Herzog-Hauck.

Eblis. See DEMONOLOGY.

Eboli (ancient *Eburi*), a town of Italy, 49 miles S.E. of Naples by rail: pop. 13,000.

Ebonite. See VULCANITE.

Ebony (Lat. *ebenum*), a wood remarkable for its hardness, heaviness, and deep black colour, is the heart-wood of different species of Diospyros (order Ebenaceæ), the genus of the Date Plum (q.v.) and other fruits. The best ebony is the produce of *D. ebenum*, a large tree of India and Ceylon; but a number of species or varieties are also of value; others present variations in colour, density, and durability, and acquire different names—e.g. *D. hirsuta* of Ceylon is Calamander Wood (q.v.), and *D. lotus* (see LOTUS) is Green Ebony. Part of the true ebony of commerce is furnished by the closely allied *Maba ebenus* of the Moluccas. The African ebony of the Cape is from species of *Euclea*. The Texas Persimmon (*D. texana*) affords a small amount of excellent ebony. Of unrelated forms may be mentioned *Jacaranda brasiliensis* (Bignoniaceæ), Blue Ebony, Jacaranda or Palsander Wood (see ROSEWOOD). Several leguminous trees also share the name, notably *Ebenus cretica*, which yields the red or brown ebony of Crete, *Dalbergia melanoxylon*, ebony of Senegal, and *Brya (Pterocarpus) ebenus*, West Indian ebony, false or green ebony. German ebony is simply yew-wood stained, and other imitations are current (see TIMBER, VENEER). Ebony is chiefly used by cabinetmakers for veneering. The ancient Greeks and Romans are thought to have obtained it either from India or Madagascar. They frequently inlaid it with ivory, for contrast of colour. It is mentioned by Ezekiel (xxvii. 15) as an article of Tyrian commerce. It was at one time used in medicine.

Eboracum. See YORK.

Ebro (Lat. *Hibērus*), a river of Spain, rising at an altitude of 2778 feet, in the province of Santander, within 20 miles of the Bay of Biscay. Thence it flows 442 miles south-eastward past Frias, Miranda, Haro, Logroño, Tudela, Zaragoza, Mequinensa, Mora, and Tortosa, till it falls into the Mediterranean. Its basin comprises 38,580 sq. miles. The mouth is choked up with sand, but a canal called the San Carlos has been carried through the delta. Affluents are the Najerilla, Jiloca, and Guadalupe from the right, and the Aragon, Gallego, and Segre from the left. The Ebro runs chiefly through narrow and sometimes rocky valleys, and its course is obstructed by many shoals and rapids. This is partly remedied, however, by Charles V.'s Imperial Canal, which extends from Tudela to 40 miles below Zaragoza.

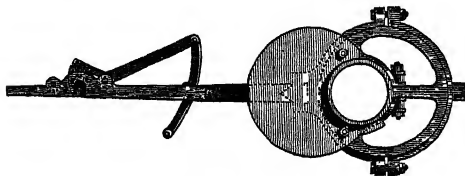

Écarté, a game played with thirty-two cards (all cards from the two to the six being removed from the pack). It is played by two persons. The player cutting the lowest écarté card deals. King is highest, then queen, knave, ace, ten, nine, eight, seven. The dealer gives five cards to each player, by three at a time and by two at a time, or *vice versa*, and turns up the eleventh card for trumps. If the turn-up card is a king, the dealer marks one; if the king of trumps is in either hand, the holder marks one. If the non-dealer is not satisfied with his hand, he may *propose* to discard. The dealer

may either *accept* or *refuse*. If he accepts, each player discards as many cards as he pleases, an equivalent number of cards being dealt from the stock. After taking cards, the non-dealer may propose again, and the dealer may again accept or refuse. The hand is next played (the king, if in hand, being first marked). The highest card of the suit led wins the trick; trumps win other suits. The second player must win the trick if he can. Three tricks count one; five tricks count two. If the non-dealer plays without proposing, and fails to make three tricks, or if the dealer refuses the first proposal and fails to make three tricks, the adversary counts two. The game is five up. *Écarté* was first played in the Paris *salons* early in the 19th century; but a similar game, called *Tromphe* or French Ruff, in which there was no score for the king, is of considerable antiquity.

Ecbatana (Heb. *Achmetha*, as in Ezra, vi. 2), the capital and chief fortress of Media. It was situated $1\frac{1}{2}$ mile from Mount Orontes (now *Elvend*), and at the foot of a hill crowned with the royal citadel and a magnificent temple of the sun. According to Herodotus, Ecbatana was founded by Deioces (about 700 B.C.), who surrounded it with seven walls, each higher than the next outside it, and having its battlements of a different colour. The inmost wall inclosed the citadel, with the treasury and the archives, among which Darius found the roll containing the edict of Cyrus for the rebuilding of the temple at Jerusalem (Ezra vi.). Ecbatana was taken by Cyrus in 549 B.C., after which it became the chief seat of his government. Its cool mountain climate made it a favourite summer residence of the Persian kings; and Alexander the Great lingered here for two months in 324 B.C. After his death Ecbatana sank to a mere provincial town, till, under the Parthians, it became once more the summer residence of kings. From the time of its conquest by the Sassanids it is scarcely again mentioned in history. In the Mohammedan period there rose on the site of the ancient city the modern *Hamadan*. Inscriptions of Xerxes have been found on the summit and slopes of Mount Elvend (10,728 feet).—There were six other Asiatic cities or strongholds to which the name Ecbatana was given by Greek writers, and Sir H. Rawlinson identifies the Ecbatana of Herodotus not with *Hamadan*, but with a hill half-way between it and Tabriz.

Ecce Homo ('Behold the man!') from the words of Pilate, cf. John, xix. 5), a name in art for a picture representing the Saviour wearing the crown of thorns, either in a half-length figure in a group (as Correggio's 'Ecce Homo' in the National Gallery), or the one head alone (as Guido Reni's).

Eccentric, in Machinery, is a contrivance for taking an alternating rectilinear motion from a revolving shaft. It consists of a disc or circular

Eccentric.

frame, fixed on a revolving shaft or axis which does *not* pass through the centre of the disc. The disc is surrounded by a hoop of metal, and to this hoop a rod is attached. When, therefore, the shaft revolves, carrying the eccentric with it, the

rod attached to the encircling hoop receives a reciprocating motion, just as it would do if attached to a crank in the shaft (see **CRANK**).

Eccentric, in pre-Copernican Astronomy. See **PTOLEMAIC SYSTEM**.

Echymosis (Gr. from *ek*, 'out of,' and *chymos*, 'juice'), a discoloration of the surface, produced by blood effused below, or in the texture of, the skin. It is attended by swelling to a greater or less extent, and is usually the result of injury (see **BRUISE**), but also occurs in disease. See **PURPURA**, **SCURVY**.

Ecclefechan, a small village of Dumfriesshire, nearly a mile from a station on the London, Midland, and Scottish Railway, 20 miles NW. of Carlisle. Its only interest is that it is the birth and burial place of Thomas Carlyle, and the 'Entepfuhr' of his famous spiritual autobiography, *Sartor Resartus*. The house in which he was born still stands.

Eccles, a municipal and parliamentary (1918) borough of Lancashire, on the Irwell (where it is merged in the Manchester Ship Canal), 4 miles W. of Manchester, is practically a suburb of Manchester; pop. 44,000.

Eccles, or **EAGLES**, **SOLOMON** (1618–83), born in London, was a teacher of the virginals and viols. About 1660 he burned his books and instruments on Tower Hill, and became a shoemaker; and in 1667, in *A Musick-Lector*, he 'doth give his judgment and sentence' against music, 'but yet approves of the Musick that pleaseth God.' His zeal, sometimes aggressive or eccentric, as when during the Great Plague he ran naked about London with a brazier of burning brimstone on his head, threatening the fate of Sodom, brought him repeatedly into trouble both at home and in the West Indies and New England. He helped to organise Quakerism in Barbados and Jamaica. It is believed that before his death he had returned to the practice and composition of music. His sons John and Henry were composers and violinists, and Thomas a violinist.

Ecclesfield, a northern suburb of Sheffield

Ecclesia (Gr., 'convocation'), a popular assembly, especially that of Athens (q.v.), where the people exercised full sovereignty, and at which every citizen of twenty years of age was entitled to vote. The Athenian ecclesia held originally four, ultimately forty, ordinary meetings in the year (see **SOLO**). The term was applied by the Septuagint translators to the Jewish commonwealth, and so was naturally adopted by New Testament writers to designate the church (compare Fr. *église*; Welsh *eglwys*).

Ecclesiastes. This title is borrowed from the Septuagint, and is the transliteration of a Greek word which means 'Preacher.' The Hebrew title is *Kohleth*, the meaning of which is more difficult to determine. Both the Authorised Version and the Revised Version render 'preacher,' but the margin of the latter translates 'the great orator.' The word itself is a feminine participle, and the noun has to be mentally supplied. Whether that noun is 'Solomon' or 'Wisdom' has been a matter of debate among scholars. The traditional view of the book maintains that it is the work of King Solomon, written late in his career, and containing his reflections upon the value of life. This theory, however, has now been entirely abandoned on the grounds that (a) the language and style of the book belong to a late stage of Hebrew; (b) the book does not reflect the conditions which prevailed in the reign of Solomon; (c) Solomon, if he had been the writer, could not have spoken of himself in the past tense as in i. 12, 'I was king over Israel;' (d) there was a tendency in the late period to ascribe books to Solomon—the Book of Wisdom,

for instance, was called the Wisdom of Solomon. Most modern scholars think that Ecclesiastes was written either at the close of the Persian period, about 320 B.C., or during the Greek period (250–200 B.C.). It was one of the latest books to be admitted into the Old Testament Canon, and for some centuries there was a controversy as to its right to a place in Scripture (see BIBLE: *The Formation of the Old Testament Canon*). Ecclesiastes belongs to the group of books known as the Wisdom Literature, and ranks, therefore, with Job and Proverbs. It contains reflections on the practical questions of life and destiny. At the time when it was written the age of faith, represented by the prophets, had passed away, and been succeeded by an age of doubt and 'obstinate questionings.' The problem with which the writer deals is, 'Is life worth living; and if it is, how can we make the best of it?' But though it is easy to state the problem, it is far more difficult to find the writer's answer to it, and many different suggestions have been made. (1) Some scholars regard Ecclesiastes as a kind of spiritual autobiography of a man who started in quest of the *summum bonum* of life, tried all the ordinary avenues which are supposed to lead to happiness, found them to be 'vanity of vanities,' and at last discovered the solution of the problem 'in the fear of God and the keeping of his commandments.' But though this is the most common interpretation of the book, it is doubtful whether it really represents its message. The references to religion as the key to the problem of life are very scanty. The one clear and definite statement is found in the epilogue (xii. 13, 14), and there is a widespread feeling among modern scholars that this epilogue is a later addition inserted for the purpose of introducing a satisfactory conclusion to the book. (2) Many interpreters have found in the book—especially in the frequent denunciations of the vanity of pleasure and wealth—a plea for asceticism, and even monasticism; but this view can scarcely be maintained in face of such explicit statements as 'There is a time to weep, and a time to laugh; a time to mourn, and a time to dance' (iii. 4); 'A man hath no better thing under the sun than to eat, and to drink, and be merry' (viii. 15). (3) A. B. Davidson thinks that the book enunciates three main principles: (a) Life is vanity; nothing is to be gained by it. 'What profit hath man of all his labour?' 'It is a sore travail that God hath given to the sons of men.' (b) Since, however, life is our portion, we must endeavour to make the best of it. 'There is nothing better for a man than that he should eat and drink, and make his soul enjoy good in his labour' (ii. 24). (c) In order to obtain the highest good from life it is necessary for a man to possess some regulating principle, and the only principle which will enable a man to secure the maximum of happiness is 'wisdom.' (4) Other scholars think that the teaching of the book is frankly pessimistic and utilitarian. Dr Peake sums up the moral of Ecclesiastes thus: 'Life is a bad business at the best, but it lies within our power to palliate its misery by prudence and the due enjoyment of what little pleasure we can get. And we should be all the more eager to make the most of our opportunities for pleasure that in the dreary darkness of Sheol no possibility of enjoyment will be found. His motto is "*Carpe diem*," and if in the abstract it be not a high motto, we must remember the misery of his time, and the absence of any hope of improvement in this world or immortality in the next.'

See articles by Davidson in *Ency. Biblica*, and Peake in *Hastings's Bible Dictionary*; Cheyne, *Job and Solomon*; Dillon, *Scriptures of the Old Testament*; the small commentaries of Plumptre (Cambridge Bible); G. C. Martin

(Century Bible); Wright, *The Book of Koheleth*; Barton (International Critical Commentary).

Ecclesiastical Commissioners. In 1835 commissioners were appointed to inquire into the revenues of the bishoprics, cathedrals, &c. of England and Wales, with a view to the more equal distribution of such revenues, and to a better provision for the spiritual necessities of the people. The commissioners presented four very valuable reports, and on their recommendation a permanent Commission was established by act of parliament in 1836. The Commission now consists of the archbishops and bishops, the deans of Canterbury, St Paul's, and Westminster, certain judges and ministers of state, eminent laymen appointed by the crown (of whom two are appointed to act as Church Estates Commissioners), and a third Church Estates Commissioner appointed by the Archbishop of Canterbury. The commissioners are a corporation, empowered to hold lands and other property. The powers of the Church Building Commissioners were transferred to them in 1856. Though the acts which relate to the Ecclesiastical Commissioners are numerous and complicated, the general outline of their duties is tolerably clear. Certain canonries, prebends, and other offices have been suppressed by parliament; the revenues of other offices have been restricted to a fixed sum, under schemes of reform prepared by the Ecclesiastical Commissioners and sanctioned by the sovereign in Council. The revenues thus set free have been carried to a common fund, out of which grants are made in aid of poor benefices and of the new districts created to meet the wants of the more populous and necessitous parts of the country. Under the Church Building Acts the Commissioners have power to divide and unite parishes, and to make new districts for ecclesiastical purposes. Reports of the work of the Ecclesiastical Commissioners are laid annually before parliament. Their proceedings have seldom led to political discussion; but the very large powers which they exercise render them liable to keen criticism from clergymen and others interested in church matters.

The Ecclesiastical Commissioners are the largest landowners in England; their estates, about 300,000 acres, comprising much of the best agricultural land in the country. The increase due to them in incomes of benefices is over £1,000,000 per annum.

Ecclesiastical Courts. In the early Christian church there were courts, presided over by bishops and presbyters, which dealt with questions of discipline, and with disputes which arose among the brethren. It is to these courts that St Paul refers when he condemns those who go to law with a brother 'before the unbelievers, and not before the saints.' When Christianity became an established religion, these courts changed their character. The state permitted church courts to exercise jurisdiction over the whole civil community in ecclesiastical matters, and in matrimonial and other causes which had to be decided by the 'law Christian.' In England and elsewhere the goods of a deceased person were distributed, or his will was proved, in the court of the 'ordinary' ecclesiastical judge, usually the bishop of the diocese: this was done, because a part of the goods went by custom to the bishop, to be spent for pious uses. The early history of the English church courts is obscure; such information as we possess will be found in the report presented to parliament by a Royal Commission in 1883. These courts became in time a fruitful source of disputes between the crown and the see of Rome. After a long struggle, the crown prevailed: clergymen were made subject to the law of the land; the king's court maintained its right to prohibit ecclesiastical judges from going beyond

their jurisdiction; appeals to Rome were forbidden, under penalty of *Premunire* (q.v.). At the Reformation the king was acknowledged as the legal head of the church, charged as such with the administration of the 'law spiritual'; the final appeal was to delegates or commissioners of review appointed by him. The final appeal in ecclesiastical cases is now to the Judicial Committee of the Privy-council. Modern legislation has greatly diminished the importance of church courts; their jurisdiction in matrimonial and testamentary causes is gone; and Acts of Toleration prevent them from exercising coercive powers over the general community (see CONVOCATION, DOCTORS' COMMONS, and DIVORCE). Under the Public Worship Regulation Act of 1874, a new ecclesiastical judge was appointed to try offences in the matter of ritual. There is a party in the church which objects to the jurisdiction of this judge and of the Judicial Committee on the ground that their decisions are not those of ecclesiastical courts in the proper sense of the term. The Bishop of Lincoln's case, tried in 1889 by the Archbishop of Canterbury, with the assistance of four bishops, raised the interesting question, by what court a bishop may be tried for alleged offences against the law of the church.

In Scotland, the church judicatories are kirk-sessions, presbyteries, synods, and general assemblies. The 'spiritual independence' of these tribunals has been the theme of much controversy, especially at the time of the Disruption of 1843 (see FREE CHURCH). The Commissary Court and the Court of Teinds are semi-ecclesiastical in their character. Both in England and in Scotland, dissenting churches have courts of their own; the jurisdiction of such courts depends entirely on contract or voluntary submission. See Sir R. Phillimore's *Ecclesiastical Law of the Church of England* (2d ed. 1895), and T. E. Smith's *Law and Practice in the Ecclesiastical Courts* (5th ed. 1902).

Ecclesiastical Law. See CANON LAW, TITHES, TEINDS; ENGLAND (CHURCH OF), SCOTLAND (CHURCH OF), ROMAN CATHOLIC CHURCH.

Ecclesiastical Titles Act was the name of a Protestant measure provoked in 1851 by an edict issued by the Papal court in 1850, dividing Great Britain into territorial bishoprics, under an Archbishop of Westminster. The Act of 1851, passed by Lord John Russell, declared the papal edict null and void, and imposed penalties on persons assuming Catholic titles named from bishoprics, deaneries, &c. in England or Ireland. No prosecution took place under the act, the popular excitement died down, and the act was finally repealed in 1871. No opposition was made to the constitution of a regular Catholic hierarchy in Scotland in 1878, with territorial titles.

Ecclesiastical Year. See YEAR, CHRONOLOGY, EASTER, FESTIVALS.

Ecclesiasticus, one of the most important books of the Apocrypha. The word Ecclesiasticus means 'belonging to the church,' or 'used in the church,' and this title was bestowed upon the book by the Vulgate to denote its popularity and its suitability for use in public worship. In the Greek versions the book is generally described as the 'wisdom of Jesus, son of Sirach,' and so it is often referred to as the Book of Sirach. The book was originally written in Hebrew by Jesus, the son of Sirach (between 190 and 170 B.C.), and translated into Greek by his grandson who bore the same name (between 130 and 120 B.C.). All traces of the Hebrew original were lost up to 1896, when Mrs Agnes Lewis brought a fragment from Palestine containing chap. xxxix. 15 to xl. 18. This discovery led to further investigations, and many other frag-

ments have now been brought to light. The book was held in very high esteem by the early Christian Church; and when Augustine, towards the end of his life, made an anthology of the passages of Scripture which he considered specially helpful for the culture of the spiritual life, the quotations from Ecclesiasticus occupied no less than an eighth of the book, twice as much space as was given to the Gospel of St Matthew.

The book consists of a number of moral apophthegms, proverbs, and counsels strung loosely together, without any definite plan or arrangement. It gives advice in the regulation of conduct under all possible circumstances and in every relationship of life. As Schmidt says, 'It teaches a man how to govern his wife, his children, and his slaves; how to deal with his friends and his foes, his superiors and inferiors, his creditors and his debtors, the rich and the poor; how to behave at the banqueting table and in the house of mourning, in the home and in the public assembly, in the temple and in the mart; how to control his passions, practise moderation, cultivate his nobler tastes, emulate the example and seek the company of the wise.' The writer's ethical outlook is utilitarian; all his sanctions are prudential; the end of morality is always the man's own well-being and happiness. He deals mainly with the external aspects of morality, and very little is said about the motives and ideals of the inward life. Another limitation is to be found in the fact that the writer's horizon is limited to the present life; rewards and punishments are therefore restricted to man's present existence. The ethical teaching of the book, too, is individualistic; no interest is taken in the national life or in society as a whole. The book affords us an excellent picture of the moral ideals and practices of the average Jew in the second century B.C., but it lacks originality (the writer describes himself as 'one that gathered after the grape-gatherers') and prophetic glow. In the hands of Sirach religion has become purely practical and entirely commonplace. There is every reason, however, for thinking that if the book had been written a little earlier, and published under a different name, it would have been admitted into the Christian Canon.

The most modern edition is that of Box and Oesterley in the Oxford *Apocrypha and Pseudepigrapha* (1913), while Oesterley's edition in the Cambridge Bible (1912) is the most useful commentary for the general reader. The best English commentary on the Greek text is that of Hart (1909). There are good articles in Hastings's *Bible Dict.* and the *Ency. Biblica*.

Ecclesiology, the study of church architecture, decoration, and archaeology. See CHURCH.

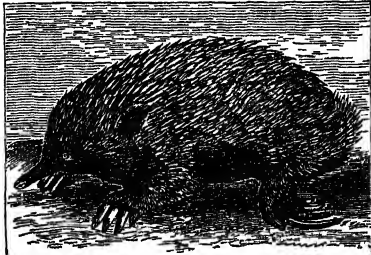

Echegaray, JOSÉ (1832-1916), born in Madrid, was professor of Physics, member of the Cortes (1868), minister of education (1873), dramatist, and minister of finance (1905). Possibly *Folly or Saintliness* (trans. by Lynch, 1895) is his masterpiece; others translated are *El Gran Galeoto*, *The Son of Don Juan*, and *Mariana*.

Echelon (Fr. *échelle*, 'ladder'), is such a formation of troops that, if viewed from a height, they would resemble a staircase. Each division behind has its front clear of that in advance, so that, by marching directly forward, it can form line with it.

Echidna, or PORCUPINE ANT-EATER, a genus included with Ornithorhynchus (q.v.) and another genus in that lowest sub-class of Mammalia which has been variously designated Monotremata, Ornithodelphia, or Prototheria. In many ways the few animals in this section are primitive—in skeleton, brain, heart, and reproductive organs especially.

None of their peculiarities, however, are more striking than their oviparous, instead of viviparous habit. They lay eggs instead of bringing forth their young as such, like other mammals. The temperature of the body is very low (in *Echidna* 28° C.), and this may be taken as a sort of physiological index of the low pitch of the life. In several features besides the egg-laying habit the Prototheria resemble birds, derived doubtless from a far back common ancestry.

The genus *Echidna* is found in Australia, Tasmania, and New Guinea. In size and general appearance the animal (as shown in the illustration) much resembles a hedgehog. The hair is partly replaced by the porcupine-like spines, which are doubtless useful in protection and in burrowing; the toes are armed with strong claws, dexterously used in rapid digging both for food and for concealment; the tail is rudimentary; the skull is prolonged into a narrow snout; the mouth, which has a very small aperture, is entirely toothless, but contains a long extensile worm-like tongue, viscid with saliva, which is quickly moved out and in for catching ants. The hind-leg or heel of the males bears a horny spur, connected with a gland on the thigh, but of unknown significance. The

Echidna aculeata.

Echidna has a better brain than the duckmole, the cerebral hemispheres being not only larger, but well convoluted. A unique skeletal peculiarity for a mammal is the incompletely ossified socket (*acetabulum*), where the thigh-bone works on the hip-girdle. In skull, mouth, feet, tail, skin, and general habit, the *Echidna* is obviously very different from the *Ornithorhynchus*. The animal is emphatically a burrower. In walking, the hind-toes are turned outwards and backwards. It feeds on ants, caught as above described, and crushed by spines on the tongue and palate. The *Echidna* is thus a prophecy of the true Ant-eaters (q.v.). The eggs are large, and inclosed in a tough egg-shell. After being laid, they are carried in a pouch developed round about the depressed area on which the milk-glands open. There are no teats.

There are several species of *Echidna*, the best known being *E. aculeata*, in Australia and Tasmania. Another form, 'with longer fur almost concealing the spines,' is distinguished as *E. setosa*. A third species—*E. laeviss*, from New Guinea—has also been distinguished. All these have five claws on each foot. A larger form, with only three claws, occurs in New Guinea, and is separated as a distinct genus, *Acanthoglossus* or *Pro-echidna bruijnii*. The upper arm of a fossil *Echidna* has been found among Pleistocene remains.

See Gould, *Mammals of Australia* (3 vols. 1845-63); Gervais, *Océographie des Monotrèmes* (Paris, 1878); Oldfield Thomas, *Proc. Zool. Soc. Lond.* (1885); Baldwin Spencer, *Nature*, xxxi. (1884-85); and Haacke on 'Oviparity,' in *Proc. Roy. Soc.* xxxviii. (1884-85).

Echinococcus. See TAPEWORM, HYDATID.

Echinodermata (Gr., 'thorny-skinned'), a well-defined division of Invertebrates, including

Holothuroidea or Sea-cucumbers (see HOLOTHURIANS), Sea-urchins (q.v.) or Echinoidea, Starfishes (q.v.) or Asteroidea, Brittle stars (q.v.) or Ophiuroidea, Feather-stars or Crinoidea (q.v.), and several wholly extinct classes, e.g. Cystoidea (q.v.) and Blastoidea. Limy depositions, forming skeletal framework, are developed to a variable, but usually predominant, degree in the middle layer or mesoderm. Most of the adults show an approximation to radial symmetry, but the larvæ are bilateral. There is a well-developed body-cavity, and from this there is separated off a peculiar water-vascular (locomotor or respiratory) system. A remarkable metamorphosis usually occurs in the life-history. They are all marine barring a few Holothurians in brackish water. They appear in the Lower Silurian strata.

Echinoidea, a sub-class of Echinodermata (q.v.). See SEA-URCHINS.

Echinorhynchus (lit. 'thorny-snout'), a genus of peculiar parasitic worms, forming the class Acanthocephala, which approaches but is quite distinct from the Nematodes. The proboscis armed with hooks, the absence of mouth or food-canal, the exclusively parasitic habit and its results, are characteristic features. There are many species, one of which has been recorded from man. The adults occur in the alimentary canal of various vertebrates—e.g. pig, duck, pike, perch; the immature forms inhabit small invertebrates (eaten by the final hosts), especially small aquatic crustaceans and terrestrial larval insects. See PARASITIC ANIMALS.

Echium. See VIPER'S BUGLOSS.

Echiurida, a group of sausage-shaped marine animals with a long proboscis (used in feeding and locomotion), and a pair of hooked bristles on the ventral surface of the body. See GEPHYREA.

Echmiadzin, or ECHMIADZIN ('the Only-begotten descended'), a monastery of Transcaucasia near the village of Vagarshabad, 12 miles W. of Erivan, the seat of the Catholicos or primate of the Armenian Church. It comprises within its crumbling 18th-century mud walls and bastions a cathedral, library, museum, seminary, unfinished new palace of the Catholicos, and incomplete observatory. Owing to renovations and extensions the monastery buildings are now almost wholly in modern style. The library is a rich storehouse of Armenian literature. The cathedral, of usual Armenian type, and with fine arabesque decorations in its dome, is said to have been founded in 302 by St Gregory, the Illuminator, on the spot where, in a vision, he had seen the earth, when struck by the golden mallet of the descended Saviour, yield up the greatest of four pedestals of gold surmounted by crosses of fire. On the other three pedestals the churches of St Rhipsimé, St Gaian, and Shoghakath were reared. In the cathedral treasury is the right arm of the Illuminator, which, enclosed in a silver case, is placed on the head of each Catholicos at his consecration, and which has for centuries been regarded as the palladium of the Armenian race. Echmiadzin was associated with the primacy from the 4th to the 5th century, when the patriarchal seat was removed first to Dvin and then to Ani; but in 1441 it was again restored.

Echo, a nymph whom Zeus employed to talk incessantly to Hera in order to keep her from observing his infidelities. The goddess discovering his artifice, changed Echo from a nymph into a mere echo. She next fell in love with Narcissus, but finding her love unreturned, pined away in hopeless grief till nothing but her voice remained.

Echo (Gr., 'sound'). Sound is produced by waves of compression and rarefaction in the air;

when such a wave comes against a wall or other opposing surface, it is reflected, and proceeds in another direction, and the sound caused by this reflected wave is called an echo. Even the surface of a cloud suffices to reflect sound, as may be observed during thunder and the discharge of cannon. That the echo of a sound may return to the point where the sound originated, the reflecting surface must be at right angles to a line drawn to it from that point. Oblique walls send the echoes of a person's voice off in another direction, so that they may be heard by others, though not by him. In order to echo words distinctly, the reflecting surface must on the whole be plane, or so curved as to resemble a concave mirror. A curved form is necessary for returning a distinct sound when the distance is considerable. Great evenness of surface, however, is not essential, as it is no uncommon thing for the edge of a wood to return an echo. The distance of the reflecting surface must also be such as to allow a sufficient time to elapse between the sound and the return of the echo for the ear to distinguish them; when they succeed too closely, they merge into one. An interval of about $\frac{1}{3}$ of a second is necessary to discriminate two successive sounds; so that if we assume 1125 feet as the distance traversed by sound in a second, $\frac{1}{3}$ of 1125, or 62 feet, will be the least distance at which an echo can be heard, as the sound will go that distance and return in $\frac{1}{3}$ of a second. If the distance is less, the echo only clouds the original sound, and is not heard distinct. It is these indistinct echoes that interfere with hearing in churches and other large buildings (see ACOUSTICS); hence anything that breaks the evenness and continuity of the reflecting surfaces is an improvement in this respect. The number of syllables that any particular echo will repeat, depends upon how many can be uttered in the time that the sound takes to go to and return from the reflecting surface. The echo at the tomb of Metella, in the Campagna, near Rome, of which Gassendi speaks as repeating a hexameter line requiring $2\frac{1}{2}$ seconds to utter it, must therefore come from a distance of about 1500 feet. Such echoes are rare, as the various conditions are seldom all fulfilled. When there happen to be several reflecting surfaces at different distances in the direction of the sound, with a sufficient interval between them, each gives a separate and distinct echo. A similar effect is produced when two surfaces are inclined to each other in such a way as to give repeated reflections of the sound from the one to the other like the mirrors of a kaleidoscope, thus producing echoes of echoes. To this multiple and repeating class belong the famous echoes of Killarney, and that produced between the wings of the castle of Simonetta, near Milan, which repeats the report of a pistol 60 times.

Echuca (formerly Hopwood's Ferry), a town of Victoria, Australia, stands on a peninsula formed by the Murray and Campaspe rivers, 156 miles N. of Melbourne. It has considerable trade in red-gum timber, wool, and wine, and important river traffic by steamer. A bridge (1905 feet) which carries a roadway and railway connects Echuca with Moama on the New South Wales side of the Murray. There are great irrigation works. The vineyards are important. Pop. 5000.

Écija, a city of Spain, in the province of Seville, 34 miles SW. of Córdoba by rail, is situated in a fertile district, producing corn, wine, and some cotton. An old Roman and Moorish town, it possesses several traces of the architecture of those peoples. On account of its great heat, it is popularly known as the 'Frying-pan of Andalusia.' The manufacture of oil and weaving are the chief industries. Pop. 30,000.

Eck, JOHANN (properly JOHANN MAIER), the zealous opponent of the Reformation, was born at the village of Eck, in Swabia, 13th November 1486. From his twelfth year he was a student, first at Heidelberg, and afterwards at Tübingen (1499-1501), Cologne, and Freiburg im Breisgau (from 1502). Having entered the priesthood in 1508, he left Freiburg in 1510 to be canon of Eichstätt and professor of Theology at Ingolstadt, and was the ruling spirit of that university till he died there, 10th February 1543. Learned and vainglorious of his great reputation for dialectic skill, he offered a challenge to Luther in his *Obelisci* (against Luther's *Theses*), attacking Carlstadt at the same time. This led to the famous disputation held in the Pleissenburg at Leipzig from the 27th June to the 16th July 1519. Eck first disputed with Carlstadt about grace and free-will, and defended the Roman Semi-Pelagianism with superior ability. Thereafter he contended at greater length with Luther for the primacy of the pope, penance, indulgences, and purgatory, and pressed the Reformer hard with the charge of Hussite heresy. Eck fought with quotations from Fathers and Councils, and sought to dazzle his numerous hearers with scholastic learning; Luther appealed to history and Scripture, and at last cried to Eck that he 'ran away from the Bible like the devil from the Cross.' Both parties claimed the victory, and at Leipzig Eck certainly achieved his object, which was to compel the great heretic to declare that disobedience to pope and council might under certain circumstances be right, and thus complete the breach between Luther and the pope. After this Eck wrote his chief work, *De Præmatu Petri*, and went to Rome in 1520 to reap the fruits of his labours. He returned to Germany with the bull of 15th June 1520, which declared Luther a heretic. Eck henceforth continued with passionate violence his struggle with the Reformation. He made two more journeys to Rome; took part in the convention at Ratisbon in 1524; opposed Œcolampadius in the Baden conference in 1526; was engaged at the Augsburg Diet (1530) in the preparation of the confutation to oppose the Augsburg Confession, and was present at the conference begun at Worms in 1540, and ended at Ratisbon in 1541. Eck's appearance at the Leipzig disputation is thus described by the humanist Petrus Mosellanus: 'Eck is a tall man, with a fat, square-built body and a full, thoroughly German voice, which, supported by his powerful loins, would do well not only for an actor, but even for a public crier; still, it is more harsh than clear. His mouth and eyes, indeed his whole countenance, are such that one would sooner take him for a butcher or a barbarian mercenary than a theologian. With respect to his mind, he has a remarkable memory; and, if he only had an understanding equal to it, the work of nature on him would be complete.' Eck collected his polemical writings under the title *Operum Joh. Eckii contra Lutherum*, tom. I.-IV. (1530-35). See Seidemann, *Die Leipziger Disputation* (Dresden, 1843); and Wiedemann, *Dr Johann Eck* (Regensburg, 1865), which has a bibliographical list of his writings (81 in number).

Eckermann, JOHANN PETER, friend of Goethe, was born at Winsen, in Hanover, in 1792. After serving as a volunteer in Kiemannsegg's rifle corps during the war of 1813-14, he was for some time employed in the war office at Hanover, and was a student (from 1817) at the gymnasium of Hanover and university of Göttingen. The publication of his *Beiträge zur Poesie, mit besonderer Hinweisung auf Goethe* (Stutt. 1823), led to his removal to Weimar, where he was employed by Goethe as his assistant in preparing the final edition of his works. After being tutor to the grand-duke's son, he

travelled in Italy with Goethe's son in 1830. He edited the poet's posthumous works in 1832-33, and in conjunction with Riemei brought out in 1839-40 a complete edition of his works in 40 vols. Eckermann was librarian to the grand-duchess at the time of his death at Weimar, 3d December 1854. He has won for himself a lasting name by his *Gespräche mit Goethe in den letzten Jahren seines Lebens 1823-32* (2 vols. Leip. 1837; 6th ed. edited by Duntzer, 3 vols. Leip. 1884). These *Conversations* are of the greatest value for the light they throw on the character of Goethe both as a poet and as a man, and contain, in Eckermann's own words, 'many valuable explanations and instructions with regard to art, science, and the practical affairs of life.' The book has been translated into all the languages of Europe. The English translations are by Margaret Fuller (Boston, U.S. 1839), and John Oxenford (Lond. 1850).

Eckernförde, a port of Sleswick-Holstein, on a fjord of the Baltic, 20 miles NW. of Kiel. It has a good harbour, an extensive fishing industry, a considerable trade in agricultural products, and manufactures of tobacco, salt, and iron goods. Pop. 7000.

Eckhart, MEISTER, one of the profoundest speculative thinkers among the German mystics. Of his personal history very little is known. He was born in either Strassburg or Saxony towards the end of the 13th century; entered the Dominican order; studied and afterwards taught in Paris; acted as prior at Erfurt, and as vicar of his order for Thuringia, before 1298; filled the office of provincial for the Dominicans in Saxony for eight years from 1303, and in 1307 was also appointed vicar-general of Bohemia; some years later he preached at Strassburg and Frankfurt, and from 1325 until 1327, the year of his death, at Cologne. Living in an age when the religious consciousness was very sensitive and alert, when the writings of such thinkers as Plotinus, Pseudo-Dionysius, Augustine, Amalrich of Bena, Albertus Magnus, and Thomas Aquinas were being eagerly studied, and the religious fervour of men's hearts was being kept aglow by the practical self-denying lives of the Beghards and Beguines, and the Brethren of the Free Spirit, Eckhart, from the first a religiously inclined nature, easily became inspired, under these almost irresistible educative influences, with the spirit of mystic speculation. But his genius led him beyond the position of his immediate forerunners, and brought him to what was virtually an independent standpoint. Instead of using his speculations as vehicles for the exposition of the orthodox theology of the church, he broke through its traditions and dogmas to the fundamental, permanent realities underlying them. His teaching begins with an explanation of the nature of God, and passes on to the consideration of man and of man's relations to God.

Being (*Wesen*) in its ultimate and most abstract form is without personality, and without differential characteristics; nevertheless, it contains within itself potentially the differentia of all existence. It is the unknown, the nothing, the negative of concrete being; the only fact known about it is that it is pure self-contained unity. This ultimate incomprehensible being is the godhead, in which God himself exists as absolute personality, but in a state of potential being, as the real selfhood of abstract being not yet personalised. Absolute personality, however, become actual self-conscious personality constitutes God the Father. The Father gives origin to the Son in the very act and moment of thus becoming conscious of himself; and the Holy Spirit is the love and will that are common to both Father and Son—that is to say, the blossoming of the process of God's revelation of

his own nature to himself. But this process does not take place under any law of temporal succession: it is a single act enduring eternally. Nor are Father, Son, and Holy Spirit three separate personalities, but one and the same quintessential personality of being. And it is precisely because the abstract potential personality in the godhead does penetrate to the comprehension of its own being, and just in this very act of self-fathoming, that it is God. In this process of God's self-revelation the world is likewise contemporaneously created; for all things exist in God ideally from eternity. In the eternal now of God's conception all things belong to the unity of the divine nature. Hence all creatures are God, and the world and God are one, the original selfhood of all things, partaking of the being of God. In like manner, I too am God. For the soul of man is an outflow from God's essence, and it exists in man without God's essence thereby in any way suffering diminution. In the soul of every individual therefore there exists a part which is in essence of the divine nature; this is the spark (*Funkeln*), which always yearns to return unto God, in order to find in him that perfect tranquillity and rest from energising which characterise the godhead. In the moment when the soul becomes thoroughly conscious of its essential selfhood, then is it divine, and enters into God's nature, and becomes united with him. But it does not become wholly absorbed in God's nature, for in the consciousness of itself it has permanent ground and warranty for its own personality and creatureship. Man, in order to achieve his ethical consummation, must therefore annihilate within himself all that appertains to self, must, in fact, expurgate all that is not of the essence of God, until his soul becomes filled with nothing but God; then does he understand God, and is indeed God, and his love is God's love. Thus the nullification of all self-regarding, all egoistic desire, an imperturbable serenity of spirit, not so much the doing of virtuous acts as the being virtue itself, the which is love, this is the supreme practical moment in the perfection of personal righteousness, the reality of life in its highest potency. This sanctification attained, all a man's acts are right and good.

Eckhart, however, in spite of the abstruse nature of his speculative teaching, was not neglectful of the practical precepts of pure Christianity, as is proved by many a passage in his sermons, and especially by his tractate *Schwester Katzei*. Nor did he lend any countenance to fastings, vigils, ecstatic visions, and similar over-devotional exercises, to which mystically inclined natures were in those days so prone. His power, both as thinker and as preacher, is attested by the commanding influence he won over his contemporaries and the best among his successors. Probably the deepest and most original thinker of his time, bold and paradoxical in the utterance of his opinions, gifted with a keen intuitive apprehension of truth that penetrated to the very heart and root-essence of things, with a mind that was essentially scientific, that refused to be satisfied with anything short of the surest realities and verities of religion, and with a heart that regarded inner discipline, the moral perfecting of man's nature, as supreme above the punctilious observance of churchly ordinances, Eckhart, by preaching the sufficiency of the individual soul to attain of itself unto immediate communion with God, struck a dangerous blow at the hierarchical pretensions of the clergy and the church. Nor did he escape the destiny that overtook original moral reformers in ante-reformation days. He was arraigned by the Archbishop of Cologne, in 1325, for having preached and taught heresy; but the accusation could not be sustained in face of Eck

hart's self-justification; at all events it fell to the ground, at least for a time, but only to be revived again two years after his death, when his writings were condemned as heretical by a papal bull of John XXII. His works consist of Latin and German sermons and tracts.

Eckmühl, a little village on the Laber, in Bavaria, 15 miles by rail S. of Ratisbon, is notable for the battle fought there, on the 22d April 1809, between Napoleon I. and the Archduke Charles of Austria, in which the latter was defeated, with the loss of 6000 men and 16 guns.

Eclampsia is the name usually given to convulsions of toxæmic origin occurring during pregnancy, labour and the puerperium. It occurs about once in 500 labours. It is usually preceded by the 'pre-eclamptic state,' which is characterised by persistent headache, nausea, thirst, diminished amount of urine, cedema of the face and hands, visual disturbances, confused mental states, and somnolence or insomnia with excitement. The pulse is slow and of high tension, and the urine contains albumen, sometimes becoming solid on boiling. Death may occur without convulsions. Eclamptic fits resemble epileptic fits, only there is no cry and no aura. They last from half to two minutes, may be repeated, and a *status eclampticus* may develop. Death is usually due to exhaustion. The nature of the toxæmia is not fully known. Treatment in the pre-eclamptic period is usually successful. The maternal mortality is from 8 to 10 per cent., with a much higher foetal one.

Eclecticism. The term eclectic (from Gr. *eklegein*, 'to choose,' 'select') was first applied in philosophy to certain Greek thinkers in the 2d and 1st centuries B.C. Stoicism and Epicureanism had subordinated the search for pure truth to that for happiness and practical virtue. Scepticism had denied that such truth could be found; Eclecticism was the attempt to reach the highest probability by selection from the already existing systems of philosophy. It arose from despair of attaining absolute truth, and from the desire for knowledge which should suffice for guidance in action. Panæti and Posidonius (later Stoics), Carneades (of the new Academy), Philo of Larissa are the chief early representatives of eclectic thought in later Greek philosophy. Philosophic eclecticism had appeared in the Sophists about the middle of the 5th century B.C. It was here also associated with, and sprang immediately from, scepticism, with which was combined a certain dogmatic tendency. Plato and Aristotle were eclectic only in a very wide meaning of the term, for the philosophic genius of each was original, and their concern for pure truth was very intense.

The chief causes of Roman eclectic philosophy were similar to those of eclecticism in Greece. Philosophic speculation was ill suited to the practical Roman mind, which was content with the most easily found explanation of man and the universe. Cicero's philosophic writings (46-43 B.C.) are chiefly ethic. They express only probable truth, and, to a large extent, like the philosophy of the Sophists, reflect what was common to all popular opinion. Cicero had studied with Epicurean, Stoic, and Sceptic teachers, and tried to unite Peripatetic, Stoic, and Sceptic doctrines. His friend Varro developed his views with greater knowledge of the history of philosophy. In the following century Seneca, the Stoic, propounded a scheme of philosophy much of which was eclectic, and most of which was determined by ethical considerations.

The last period of Greek philosophy—i.e. in the 2d and 1st centuries B.C., was characterised by a weak eclecticism—viz. that of the Neo-Pythagoreans, the Pythagorean Platonists, and the

Platonic Stoics. In the 1st century B.C. a new eclecticism appeared at Alexandria, the chief representative of which was Philo, a Jew (perhaps about 25 B.C. to 45 A.D.), who interpreted the Old Testament in an allegoric sense, and in harmony with selected doctrines of Greek philosophy. These, in turn, were modified so as to remove their inconsistency with the sacred writings. He was directly indebted to Pythagorean, Platonic, Peripatetic, and Stoic schools for much of his thought. Neoplatonism, the last product of Greek speculation, was not syncretic, for it sifted and transformed the principles which it borrowed from other systems. Its fundamental doctrine of ecstasy, or immediate knowledge of God, in which the distinction of the human soul from the divine reason is completely removed, differs greatly from preceding similar theories both Greek and Oriental. It was a fusion of Greek philosophy with Oriental religion in which, however, the first element greatly predominated. The principal exponents of this philosophy are Plotinus (205-270), Porphyry (233 to about 302), Iamblichus (died about 330), and Proclus (410-484). Its purpose was religious—viz. the attainment of right relations between God and man.

There was much eclecticism in the earliest Christian philosophy. Among the Fathers of the Church Clement of Alexandria and his pupil Origen were greatly influenced by their study of Greek philosophy in Alexandria, and Christian scholasticism was pervaded by an eclectic spirit. Eclecticism was naturally a chief factor in the philosophy which immediately followed the revival of learning. It appears towards the end of the 13th century in the works of Meister Eckhardt in Germany, and in those of G. Bruno and Campanella in Italy in the 16th century. In Leibniz (1646-1716) it becomes strictly scientific. He went into his philosophy materials from widely separated sources—e.g. from Aristotle and from Descartes. Like Hegel and Cousin, he regarded the tenets which he adopted as being imperfect in the systems from which they were taken, but as capable of being made parts of one harmonious whole in which pure truth would be completely realised. He tried to unify principles which should be applied and developed in future systems, and to find a method which philosophers of diverse schools could employ in common. Perhaps it is in the effort to establish such a method that philosophic eclecticism produces its best results. The followers of Leibniz, C. Wolf (1679-1754) and his school, degraded the eclecticism of their master into a popular, dogmatic, fixed, and formal body of doctrine. Kant and Hegel are only eclectic in the sense in which Plato and Aristotle are so. Each seeks first, through criticism, to establish his fundamental principles. The greatest modern eclectic philosopher is Victor Cousin (1792-1867). He was the pupil of Royer-Collard and Maine de Biran, through whom he became acquainted, respectively, with Scottish philosophy and the sensualism of Locke and Condillac. He was particularly guided by the philosophy of Scotland and Germany, although he sought to discover the common and permanent elements in all preceding schemes of thought. His principle of selection was supplied by his psychologic analysis, which, however, was somewhat superficial. Cousin's school in France was large and influential. Its most distinguished members were Théodore Jouffroy and B. Saint-Hilaire. There is a strongly eclectic tendency in Italy.

It is only provisionally that eclecticism can aid philosophic research, for systems may arise in which psychologic investigation, or historic interpretation, or metaphysical speculation, reveals new truth. What is common to all philosophy in one age will cease to be so in another, and reality must be

sought not merely for its own sake, but by the original exercise of the individual intellect.

Eclipses. An eclipse is an obscuration of one of the heavenly bodies by the interposition of another, either between it and the spectator, or between it and the sun. The causes of eclipses, as suggested in this definition, are so simple and familiar that it is difficult for us to imagine how deeply eclipses affected men's minds before the dawn of astronomical science. To the ancients they were without the order of nature—terrible presages of dire events; and at Rome, at one time, it was blasphemy, and punished by law, to talk publicly of their being due to natural causes. So strong a hold had this superstition on the popular mind that even after it came to be generally believed that eclipses of the sun were caused by the moon coming betwixt us and that orb, eclipses of the moon were still referred to supernatural agency. When the moon was in eclipse, the people turned out and made a great noise with brazen instruments—the idea being that by doing so they gave her ease in her affliction. According to some, Luna, when in eclipse, was in the pains of labour; according to others, she was suffering from the arts of wicked magicians. Similar notions have prevailed among all barbarian tribes. The Chinese populace, as is well known, imagine eclipses to be caused by great dragons trying to devour the sun and moon, and accordingly they beat drums and brass kettles to terrify the monsters into letting go their prey. Several stories are told of these popular superstitions being turned to good account by knowing persons; among which are those which represent Thales as bringing about peace between the Medes and Lydians, and Columbus, when in a great strait, procuring provisions from the natives of Jamaica through the prediction of eclipses.

Stars, planets, and the satellites of planets may suffer eclipse. The principal eclipses, however, are those of the sun and moon, called the solar and lunar eclipses. The transits of the inner planets over the face of the sun are partial solar eclipses; but solar eclipses, properly so called, are those caused by the interposition of the moon between the sun and earth. They therefore always take place at the time of new moon, when the sun and moon are in conjunction—i.e. on the same side of the earth. In a partial eclipse the sun's disc loses its circular form; it becomes indented on one side, the indentation slowly increasing for some time, and then diminishing until it disappears altogether. In a total eclipse the indentation goes on increasing till the whole orb for a time disappears; after a short interval the sun reappears again, passing through the same phases of obscuration in an inverse order. In an annular eclipse the whole orb is obscured except a ring or annulus. Lunar eclipses always take place at full moon, or when the sun and moon are in opposition—i.e. on opposite sides of the earth—and are caused by the moon passing through the earth's shadow. Such eclipses are sometimes partial and sometimes total, but never annular, and in their general phases they resemble those of the sun.

In speaking of eclipses we shall have occasion to use certain terms which we will now define. The *duration* of an eclipse is the time of its continuance, or the interval between immersion and emission. *Immersion*, or incidence of an eclipse is the moment when part of the luminary begins to be obscured; *emission* is the time when the luminary completely reappears or emerges from the shadow. The *magnitude* of the eclipse denotes the fraction of the diameter which is obscured at mid-eclipse. It was formerly indicated by *digits* from 1 to 12, but now a decimal notation is employed. The word *eclipse* is, through the old French and Latin, from the

Greek *elleipem*, to fail to appear; and the famous race-horse Eclipse was foaled on the day of a notable eclipse of the sun, 1st April 1764.

Having given this general explanation of the facts of observation on which the theory of eclipses turns, and of the language employed in speaking of them, we now proceed briefly to explain the theory itself, and how it is possible to predict the time of occurrence, and the duration and quantity of eclipses.

(1) *Eclipses of the Moon.*—It has been said that these are caused by the moon passing through the earth's shadow. Before this explanation can be accepted, it must be shown that that shadow extends as far as the moon. This is easily done. Supposing the earth to have no atmosphere, then the shadow is the cone marked in shade in fig. 1,

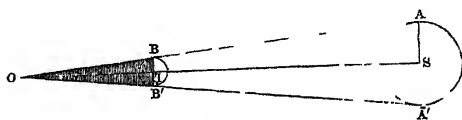

Fig. 1.

whose apex is at O; and the question is, whether the distance OT from the apex to the earth's centre exceeds the moon's average distance from the earth. In the diagram S is the centre of the sun, T of the earth. From the known values of the sun's diameter and distance, it follows that the distance OT is about 217 times TB (the earth's radius), while the moon's mean distance is only 60 times TB. At this distance the breadth of the shadow is about three times the diameter of the moon, and thus, if it is a direct line, the whole of the moon will be in the shadow.

In the foregoing explanation, we proceeded on the assumption that the earth has no atmosphere. If the assumption were correct, the earth's shadow would be darker and narrower than it is, and the phenomena of eclipses shorter in duration, but more striking. The effect of the atmospheric refraction (see REFRACTION) is to bend the rays which are incident on the atmosphere in towards the axis of the cone of the earth's shadow, those which pass through the lowest strata of the air being most refracted, and converging to a point in the line OT (see fig. 1), at a distance equal 42 radii of the earth from the earth's centre. Accordingly, the moon, which, as we have seen, crosses the shadow at a distance of about 60 radii, never enters that part of it which is completely dark; thus, she never loses her light entirely, but appears of a reddish colour resembling tarnished copper—an appearance caused by the atmospheric absorption (which is very great for blue light), in the same way as the ruddy colour of the clouds at sunset. There is another reason why the phenomena are less striking than might be expected from the explanation given. Every shadow cast by the sun's rays necessarily has a penumbra, or envelope, on both sides of the true shadow. In the case before us (fig. 2), suppose a

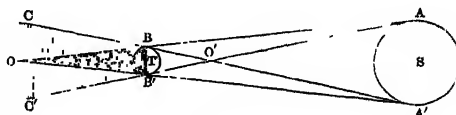

Fig. 2.

cone having its apex O' between the sun and earth, and enveloping each of them respectively in its opposite halves, CO'C' and AO'A' (fig. 2). It is clear that from every point in the shaded part of the cone CO'C', and without the shadow BOB', a

portion of the sun will be visible—and a portion only—the portion increasing as the point approaches either of the lines CB, C'E; and diminishing as it approaches the lines BO, B'O. In other words, the illumination from the sun's rays is only partial within the space referred to, and diminishes from its extreme boundary lines towards the lines BO, B'O. When, then, the moon is about to suffer eclipse, it first loses brightness on entering this penumbra, so that when it enters the real shadow, the contrast is not between one part of it in shade and the other in full brilliancy, but between a part in shade and a part in partial shade. On its emersion, the same contrast is presented between the part in the umbra and the part in the penumbra. What we should expect on this geometric view of the earth's shadow actually happens. From the breadth of the penumbra, it happens that the moon may fall wholly within it before immersion in the umbra commences; and so softly do the degrees of light shade into one another, that it is impossible to tell exactly when any remarkable point on the moon's surface leaves the penumbra to pass into the umbra, or the reverse. Also, even when the moon is wholly within the penumbra, it is impossible by the eye to discover any diminution of her light. This is only appreciable over a part of her surface when she is just about to enter on the shadow.

(2) *Prediction of Lunar Eclipses.*—We said that lunar eclipses only happen at full moon. They do not happen every full moon, because the moon's orbit is inclined at an angle of $5^{\circ} 9'$ nearly to the ecliptic, on which the centre of the earth's shadow moves. (See the article ECLIPTIC below; also the articles MOON, EARTH). If the moon moved on the ecliptic there would be an eclipse every full moon; but, from the magnitude of the angle of inclination of her orbit to the ecliptic, an eclipse can only occur on a full moon happening when the moon is at or near one of her nodes, or the points where her orbit intersects the ecliptic. An eclipse can happen only when the centres of the circle of the earth's shadow and of the moon's disc approach within a distance less than the sum of their apparent semi-diameters; except when near the nodes, the moon, on whichever side of the ecliptic she may be, may pass above or below the shadow without entering it. (1) If, at the time of full moon, the distance of the sun's centre from the nearest node be greater than $12^{\circ} 3'$, there cannot be an eclipse; (2) if at that time the distance of the sun's centre from the nearest node be less than $9^{\circ} 31'$, there will certainly be an eclipse; (3) if the distance of the sun's centre from a node be between these values, it is doubtful whether there will be an eclipse, and a detailed calculation must be resorted to, to ascertain whether there will be one or not. Before the laws of the solar and lunar motions were known with anything like accuracy, the Chaldeans discovered how to predict lunar eclipses with tolerable correctness by means of the lunar cycle (see CYCLE) of eighteen Julian years and eleven days. Their power of prediction depended on the fact that in 223 lunations the moon returns almost exactly to the same position in the heavens. If she did return to exactly the same position, then, by simply observing the eclipses which occurred during the 223 lunations, we should know the order in which they would recur in all time coming. As it is, eclipses do recur in the same order during several such successive periods, and so can be predicted fairly well. Lunar eclipses, however, change their phase at each return. They appear at first as partial and very small, increasing at each cyclical return as the small defect of exactness in the period accumulates. Becoming at last total, they again diminish until gone. This process requires a considerable time. A lunar eclipse,

beginning some centuries ago, was total in 1692, and last returned, as one of only $\frac{1}{10}$ th of the moon's disc, in 1872.

All lunar eclipses are universal, or visible in all parts of the earth which have the moon above their horizon, and are everywhere of the same magnitude with the same beginning and end; and this universality of lunar eclipses is the reason why it is popularly thought, contrary to the fact, that they are of more frequent occurrence than solar eclipses. The eastern side of the moon, or left-hand side as we look towards her from the north, is that which first immerges and emerges again. The reason of this is, that the proper motion of the moon is swifter than that of the earth's shadow, so that she overtakes it with her east side foremost, passes through it, and leaves it behind to the west. It will be readily understood, from the explanations given above, that total eclipses and those of the longest duration happen in the very nodes of the lunar orbit. But from the circumstance of the circle of the shadow being much greater than the moon's disc, total eclipses may happen within a small distance of the nodes, in which case, however, their duration is the less. The farther the moon is from her node at the time, the more partial the eclipse is, till, in the limiting case, she just touches the shadow, and passes on unobscured.

(3) *Eclipses of the Sun* are caused, as we have stated, by the interposition of the moon between the earth and sun, through which a greater or less portion of the sun is hid from view of the earth's inhabitants.

By a process similar to that used in ascertaining the length of the earth's shadow, it can be shown that the greatest value of the length of the moon's shadow is $59\cdot73$ semi-diameters of the earth; at the same time, we know that the least distance of the moon from the earth is about $55\cdot95$ semi-diameters. It follows that when a conjunction in line of the sun and moon happens at a time when the length of the shadow and the distance of the moon from the earth are, or are nearly, equal to the values above stated, the moon's shadow extends to the

Fig. 3.

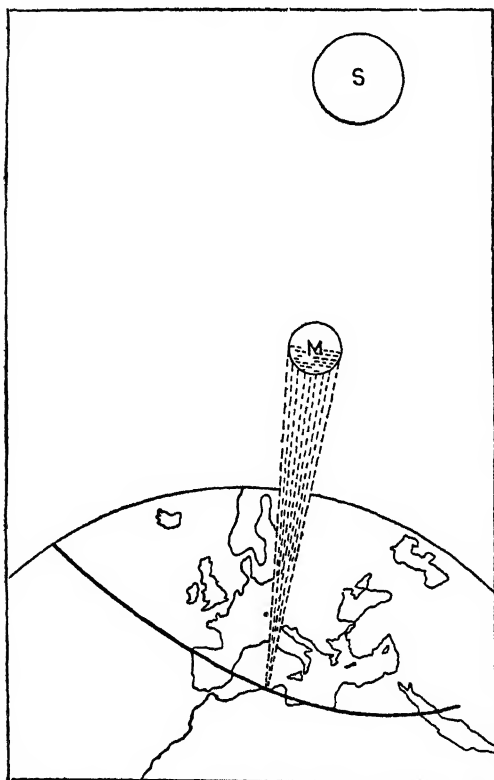

earth and beyond it. In this case there will be a total eclipse of the sun at all places over which the shadow moves (fig. 3). If L be the moon, T the earth, and abL the moon's shadow cast by the sun, there will be a total eclipse of the sun at every point that is completely within the portion ab of the earth's surface. Again, the smallest value of the length

Fig. 4.

of the moon's shadow may be shown to be $57\cdot76$ semi-diameters of the earth, and the greatest distance of the moon from the earth is $63\cdot82$ semi-diameters. So that in reality the point of the shadow at O may be as much as 15,500 miles beyond the earth, or fall short of it more than 23,000 miles. In the latter case, the sun cannot

be altogether hid from any point of the earth's surface; but this case, or one approximate to it, is that in which there will occur an annular eclipse. In fig. 4, suppose *O* to be the apex of the shadow which falls short of the earth, and conceive the cone of the shadow produced earthwards beyond *O* into a second cone *Ocd*; then, from every point

Track of the Moon's Shadow in the Total Eclipse of the Sun of 1905, Aug. 30.

within the section *cd* of the earth's surface, the moon will be seen projected as a black disc on the bright disc of the sun, the portion unobscured forming a ring or annulus of light. While in the two cases just described the eclipse is total or annular at places within *ab* or *cd*, it will be partial at other places; the moon will appear projected against a portion of the sun's disc, making a circular indentation. To ascertain the places at which the eclipse will be partial, we have merely to form the cone of the penumbra of the moon's shadow in the manner explained in treating of lunar eclipses; at all places on the earth's surface within that cone there will be a partial eclipse. A simple calculation shows what is the observed fact, that the cone of the penumbra is not nearly large enough to embrace the whole of the face of the earth directed to the sun; in other words, solar eclipses are not universal, like those of the moon—i.e. they are not seen from all places that have the sun above their horizon at the time of the eclipse, which is the reason that though they are of more frequent occurrence than lunar eclipses, the latter are commonly supposed to occur more frequently.

The breadth of the belt traversed by the umbra, when the sun's distance is greatest and the moon's least, is estimated at about 180 miles; and in the

same case the penumbra is estimated to cover a circular space of 4900 miles in diameter, the eclipse happening exactly at the node. If the eclipse does not happen at the node, it is clear that the axis of the shadow must be inclined to the plane of the ecliptic, that the shadow will be cut obliquely, and therefore that the part of the earth in shade will be oval. Astronomers usually calculate beforehand the motion of the shadow over the earth's surface, and prepare charts.

The commoner phenomena of an eclipse of the sun are perfectly analogous to those of lunar eclipses, save when the eclipse is annular; but there are other appearances, especially when the eclipse of the sun is total, that are very remarkable. The almost instantaneous darkening, even when expected, fills the mind with awe. The sudden darkness, further, resembles neither the darkness of night nor the gloom of twilight. The cone of the moon's shadow, though it completely envelops the spectator, does not enclose the whole atmosphere above his horizon. The mass of unenclosed air accordingly catches the sunlight, and reflects it into the region of the total eclipse, making there a peculiar twilight. Stars and planets appear, and animals are dismayed. De la Rue says of the total eclipse of July 1860, as seen in Spain: 'When the sun was reduced to a small crescent, the shadows of all objects were depicted with great sharpness and blackness, reminding one of the effects of illumination with the electric light. The sky at this period assumed an indigo tint, and the landscape was tinged with a bronze hue.' A total eclipse of the sun gives an opportunity of observing some solar phenomena which are invisible at all other times. As long as the total eclipse lasts, there appears round the sun and moon a luminous corona as in fig. 6, while at its base, and projecting beyond the dark edge of the moon, appear very brilliant prominences, generally red. These may be referred to in an observation noted in 334 A.D.; they were first certainly referred to by Stannyan in 1706. They are found to be constant attendants on eclipses, and methods have been invented of rendering them visible at any time without the interposition of the moon. The spectroscope shows

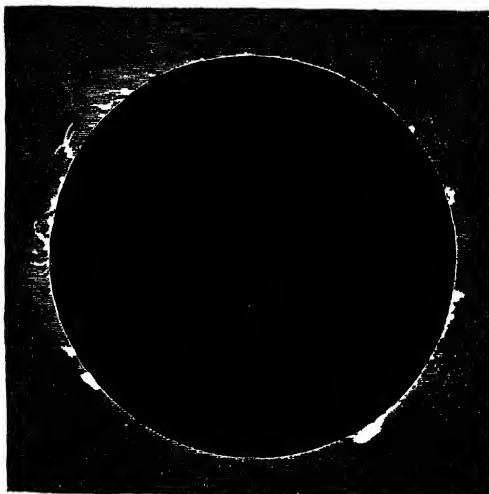

Fig. 6.—Total Eclipse observed in America, August 1869.

that they consist of hydrogen, calcium, iron, and other metals in an incandescent state. The prominences are sometimes seen to shoot up like flames, in wild fantastic shapes, with incredible velocity, and to

the height of tens of thousands of miles. Attempts have been made to photograph the corona without an eclipse. These have failed, and it is only on the rare occasions of eclipses that this remarkable solar appanage can be studied. Modern expeditions to observe solar eclipses are almost entirely devoted to the photography, spectrographic and polariscopic, study of the corona. See SUN.

The eclipses of 1919 and 1922 were utilised to verify a prediction by Einstein that the ray of light from a star to the earth would be bent in its passage near the sun, in accordance with the theory of gravitation put forward in the generalised theory of relativity. See SUN, RELATIVITY.

(4) *Prediction of Solar Eclipses.*—The period of 18 Julian years 11 days, referred to in treating of the prediction of lunar eclipses, applies to solar eclipses equally with lunar; but the ancients, who understood that fact, could find no law of recurrence of solar eclipses within that period, so as to predict them. The reason of the failure is obvious; for though solar eclipses recur in a fixed order within the cycle, they are not visible at the same places on their recurrence as when first observed. By modern methods similar to those applied in the case of lunar eclipses, however, eclipses of the sun may be predicted, with all their circumstances of time and places of observation, with the most perfect certainty. At the time of a solar eclipse the sun and moon are in conjunction; they are also in or near the same node; and no eclipse can happen if they are farther than 17° from the node, or if the latitude of the moon, viewed from the earth, exceeds the sum of the apparent semi-diameters of the sun and moon. When within these limits, detailed calculation is necessary to ascertain the nature of the eclipse, if any, which will happen.

The number of eclipses of the sun and moon together in a year cannot be less than two, or more than seven; the most usual number is four, and it is rare to have more than six. The explanation of this limitation is that the sun passes by both nodes but once in a year, except in the cases of his passing one early in the year, in which case, owing to the recession of the moon's nodes, he will again pass it a little before the end of the year. From the sun's thus passing each lunar node usually every year, it results that eclipses occur at particular periods, called *eclipse seasons*. In 1887 these occurred in February and August. They come about twenty days earlier every year, and last thirty-six days for solar, and twenty-three days for lunar, eclipses. Their annual change of date is due to the motion of the lunar node (see MOON). From the smallness of the cone of the moon's shadow, total solar eclipses are extremely infrequent in any one place, compared with the frequency of their actual occurrence. In London not one total eclipse was witnessed for the 575 years 1140–1715, nor will another be seen during the succeeding five centuries. There will be a total eclipse visible in the north of England on June 29, 1927. Total eclipses of the moon are more frequent; on an average, one may occur every two years. Oppolzer, in his *Canon der Finsternisse*, gives dates and paths of 8000 eclipses of the sun and 5000 of the moon extending from B.C. 1207 to A.D. 2161, on account of their astronomical and chronological interest. His work has been supplemented by Ginzel.

The following table gives the total eclipses from 1925 to 1940:

Date.	Duration.	Where Visible
1925. Jan. 24	2-4 minutes.	United States.
1926. Jan. 14.	4-2 "	E. Africa, Sumatra, Philippines
1927. June 29.	0-7 "	Scotland, Scandinavia.
1929. May 9.	5-1 "	Sumatra, Philippines.
1930. Oct. 21.	1-9 "	Pacific, Patagonia.

Date	Duration.	Where Visible.
1932. Aug. 31.	1-5 minutes.	Canada.
1934. Feb. 14.	2-7 "	Borneo.
1936. June 19.	2-5 "	Greece, Central Asia, Japan.
1937. June 8.	7-1 "	Pacific, Peru
1940. Oct. 1.	5-7 "	Brazil, S. Africa.

For the identification of ancient eclipses of the sun, with references made to them in early writings, see Fotheringham, *Monthly Notices of the Royal Astronomical Society* for December 1920.

Eclipses of the moon, which can be seen from all places where the moon is above the horizon, occur on the following dates:

1925 Feb. 8; Aug. 4	1934 Jan. 30; July 26.
1927. June 15; Dec. 8.	1935. Jan. 19; July 16.
1928. June 8; Nov. 27.	1936 Jan. 8; July 4.
1930. April 13; Oct. 7.	1937. Nov. 18.
1931. April 2; Sept. 26.	1938. May 14; Nov. 7.
1932. March 22; Sept. 14.	1939. May 8; Oct. 28.

See the articles MOON, SUN, EARTH, OCCULTATIONS, SATELLITES.

Ecliptic is the name given to the great circle of the heavens round which the sun *seems* to travel, from west to east, in the course of a year. It took its name from the early observed fact, that *eclipses* happen only when the moon is on or near this path. A little attention about sunset or sunrise shows that the sun is constantly altering his position among the stars visible near him, leaving them every day a little farther to the west; and that this motion is not exactly east and west, or parallel to the equator, becomes also evident by observing that the sun's height at mid-day is constantly altering. It is further observed that, twice a year, about March 21 and September 23, the sun is exactly on the equator. The two points of the equator on which the sun then stands are the equinoctial points, and are the intersections of the equator and ecliptic. Again, there are two days in the year on which the sun reaches his greatest and his least mid-day elevation: the first is the 21st of June, the second is the 21st of December. On these days the sun has reached his greatest distance from the equator either way, and the points in his course where he thus seems to pause or halt in his retreat from the equator are called the solstices (*solis stationes*). These four points are distant from one another by a quadrant of the circle, or 90° . Each quadrant is divided into three arcs of 30° , and thus the whole ecliptic is divided into twelve arcs of that length, called Signs of the Zodiac (q.v.). These arcs or signs have been named after constellations through which the ecliptic passes. As the equinoctial points are not fixed, but recede yearly westwards on the ecliptic about 50 seconds, and in a century about $1^\circ 23'$, the same constellations and signs that coincided when the division of the ecliptic took place, no longer coincide. The constellation of the Ram, for instance, which originally stood in the first arc or sign, now stands in the second, every constellation having advanced forward 30° , or a whole sign. This is due to a movement of the equator (see PRECESSION OF THE EQUINOXES). Modern astronomers, therefore, pay little attention to these constellations and signs.

Not only do the equinoctial points change, but the angle of inclination of the ecliptic to the equator, called the obliquity of the ecliptic, is also variable. It is at present nearly $23\frac{1}{2}^\circ$, and is diminishing at the rate of about 48 seconds in a century. The decrease, however, has a limit, the obliquity oscillating between two definite bounds. It has been calculated that it was at its greatest 2000 B.C., and was then nearly $23^\circ 53'$. Since then it has been decreasing, and will continue to do so till about the year 6600 A.D., when it will be at its least, and about $22^\circ 54'$. This is due to a real movement of the *ecliptic*.

The physical cause of this change of the obliquity is the action of the other planets, especially Jupiter, Mars, and Venus, on the mass of the earth. Its existence was known to astronomers in very ancient times; Herodotus mentions an old tradition of the Egyptians, that the ecliptic had formerly been perpendicular to the equator—a notion into which they were most probably led by observing, for a long series of years, that its obliquity was constantly diminishing. It is probable that the Chaldeans arrived at the epoch of 403,000 years before the entry of Alexander into Babylon, to which they proudly referred for their first astronomical observations, by computing the time when the ecliptic was perpendicular to the equator, on the supposition of its obliquity diminishing 1' in 100 years. The first known measures of this obliquity were made in the East by Tcheou Kong, regent of China (1100 B.C.), and in the West by Pytheas (330 B.C.) and Eratosthenes (200 B.C.).

Eclogite, or **EKLOGITE**, a crystalline rock composed of the beautiful grass-green amphibole, called smaragdite, and red garnet. Another variety of eclogite is composed of omphacite, a grass-green granular variety of pyroxene, and garnet. Eclogite is not an abundant rock; it is usually associated with the older crystalline schists, but as a rule is not itself schistose.

Eclogue (Gr. *eklegein*, 'to select'), a short pastoral poem, in which the swains converse with one another in turn, as in the eclogues of Virgil, also called Bucolics (q.v.). The earliest modern bucolics were Petrarca's; the earliest in English were those of Alexander Barclay (q.v.).

Ecole Normale, Polytechnique. See **POLYTECHNIQUE, EDUCATION**

Ecology, or **ECOLOGY** (*oikos*, 'a home,' and *logos*, 'a theory'). The living organism and its environment are so closely interlinked that the study of the one—Biology—cannot be disconnected from the other—Ecology. In its broader sense ecology takes account of all the environment or habitat, including physiographical factors relating to the air above and the earth or other substratum, and the biological factors involved through the presence of other organisms. The concentration of observation on the environment of living organisms is a comparatively recent development, and the earlier stages have reference mainly to plant ecology. Yet it is not difficult to foresee a wider extension into the animal world and into human economics. The elucidation of problems in plant-life underlies all animal ecology, because animals and non-green organisms depend ultimately for their nutrition on the activities of green plants containing chlorophyll. Thus the presence or absence of grazing-grounds for herbivorous animals will determine the existence of the carnivore, the parasite, and a long train of organisms, man included, that follow the green plant.

The definition of ecology as the branch of science concerned in the reciprocal relations of organisms and the external world was used by E. Haeckel (1866) and by Reiter (1885); see also **ENVIRONMENT**. The same decade also saw the beginning of the labours of the earlier plant ecologists, including E. Warming in Denmark, O. Drude in Saxony, C. Flahault in France, and C. Schröter in Switzerland. The investigations from the schools founded by these and other more recent ecologists refer mainly to plant-ecology, though many of the general principles are equally applicable on the animal side, and already there are signs of activity in this direction.

A fundamental principle of ecology is that the organism is the expression of its environment. A

plant or animal inhabits a place because the habitat suits it, and because the organism is able to maintain its place by adaptations in form and mode of life conformable to the conditions of the habitat. Some examples may recall types of vegetation familiar to any one who wanders through Britain. The heather, or ling (*Calluna*), covers many miles of northern hill and southern heath, and it is the expression of its environmental conditions. The landscape is bleak and the soil so sterile that few attempts have been made to plough it, so that the dwarf, slow-growing heather (*Calluna*), bell-heaths (*Erica*), bilberry and its relatives (*Vaccinium*), wiry grasses, and other fugial species retain possession. The grouse finds here its food-supply and other conditions favourable to existence. In contrast, woods formerly occupied large areas in the lower valleys and plains, but the soil and situation were so favourable that the farmer has left only fragments of the original forest. Trees like oak and beech, by their larger size and deciduous leaves, indicate greater requirements, some of which are a better water-supply, deeper soil, and shelter from excessive wind. Under the trees are thin-leaved ferns and shade-plants of the taller undergrowth, or the delicate anemone, primrose, wood-sorrel, and mosses of the ground carpet. An animal world of higher and lower organisms, mostly unknown on the heather moors, finds its environment in the woods. Other habitats for plants are provided through the erosion and deposition effected by streams. Amongst others, deposits of mud become the habitat of tall marsh plants, examples of the greatest annual production of vegetable matter found anywhere in Britain. Where such areas can be drained, as in the English fens, a fertile ploughland becomes available. The same mud deposited on the sea coast (e.g. Norfolk and Lancashire), and frequently irrigated by tidal waters, bears a close carpet of fleshy plants expressive of an environment where excess of salt and wind-driven spray are dominant factors. The sea-shore golf-links with adjacent sand-hills and drifting sand-dunes furnish another typical coastal vegetation.

The evolution of an organised system of grouping plants according to their habitats is necessarily dependent on the progress of correlated branches of science. All recent advances in geography, climatology, soil-knowledge, and on the form, structure, and functions of plants and animals, have a bearing on ecology. The subject can thus be approached from several directions, and this has been the case in its development. Each worker tends to have his own points of view, often traceable to his environment, and several schools have arisen in Europe and America, rather to the confusion of the beginner, but of great advantage in the evolution of a new science.

Some of the fundamental concepts necessary to understand ecology will now be briefly indicated.

Plant-physiognomy.—One of the earlier attempts to systematise types of vegetation was made by A. Humboldt (1806; English edition, 1849). Utilising his own wide experiences and those of earlier botanist-explorers, he enumerated certain plant-forms prominent in various landscapes—e.g. the cactus-form of the desert, the broad-leaved banana-form of the tropical rain-forest, the grasslands of steppe and prairie, the tall pine-wood and the dwarf heath-shrubs of the northern hemisphere, and the evergreen laurel type of the Mediterranean. This physiognomic system marks the recognition of the influence of vegetation on the character of the landscape. Another important effort was that of Grisebach (1872), who outlined a larger series of types to meet the increasing knowledge of the plant geographer. He also suggested that the

physiognomic type is correlated with the environment, especially with climatic conditions. Thus the northern tundra of Europe owes its landscape features largely to the dwarf, small-leaved plant-covering, which, under similar climatic conditions, appears again on the Alps and near the summits of our higher mountains. In northern Siberia and northern Canada a similar type of vegetation appears, and yet not the same as regards the plant species composing it. Similar parallel series are presented in the physiognomy of the pine-forest zone of the three northern continents, and farther south by the deciduous forests of birch, poplar, and oak. This distribution, according to latitudinal climatic zones, is in a general way repeated in ascending any snow-topped range of mountains, even on those which have their base in the tropical plains of Central Africa. This comprehensive treatment of vegetation on a world wide scale finds its more recent expression in A. Schimper's *Plant Geography upon a Physiological Basis* (English edition, 1903). Vegetation is here grouped primarily by climatic factors, secondarily by soil factors, and the treatment shows evidence of the great advances in experimental plant-physiology initiated by Sachs about 1866. Physiognomy is now an important feature in all recent works on the plant geography of foreign lands.

The Plant Community.—Grisebach (1838) recognised that the vegetation of any area is made up of units, which he called 'plant formations.' This unit group of plants is a feature of the landscape, such as a wood, a grassland, or a heath. It may be characterised by one social species, as in the case of a pine-wood, an oak-wood, or our northern heather moorland; on the other hand, there may be, as in grassland, several species dominant simultaneously or at different times of the year. Such a plant community is made up of (a) one or more dominant species; (b) secondary social species capable of taking the place left by removal of the dominant; (c) dependent species protected by the more dominant, or living upon the humus and other products formed. The ecological study of the vegetation of a country seeks (1) to ascertain the chief communities; (2) to outline the physiognomy of the vegetation and the landscape; (3) to investigate the special habit and habitat of each species and the reasons why the species become aggregated into communities. The importance of the concept of the plant community cannot be over-estimated. The earlier botanists of Europe perceived this vaguely, but there was little application of the principle because floristic botany—i.e. the discovering, naming, and classification of species—still prevailed. The recognition of the plant community as a unit of vegetation came in the last decade of the 19th century, when three important text-books on plant geography definitely adopted it: O. Drude, *Pflanzengeographie* (1890); Warming, *Ecology of Plants* (1895; English edition, 1909); and Schimper, *Plant Geography* (1898 and 1903). The term 'plant community' is used here to indicate any natural aggregation of species on the same habitat, but even a limited experience will show that there are grades of communities. The present tendency is to call the larger units plant formations, such as those traceable to climate or some distinct soil condition; in Britain, oak-forest, calluna-heath, moor on deep peat, coast salt-marsh and coastal sand-dune may be called formations. Smaller units which together make up the formation are plant associations, while still smaller units of gregarious species, like anemone or dog's mercury (*Mercurialis*) in a wood, or marion-grass (*Ammophila*) on a sand-dune, may be called plant societies. Exactly where each begins and ends is still a subject of academic debate, but the idea is that they should

be in ecological botany what genus, species, and variety, respectively, are in taxonomic botany.

Growth-forms.—This reveals itself in the habit of growth, the duration of life, and in the form and structure of the leaf and other vegetative organs, but it is less evident in the reproductive organs. E. Warming, the pioneer of the Danish school, was the first to demonstrate how even the commoner plants had been imperfectly studied, especially as regards leaf-form, underground parts, and mode of passing the winter or other resting period. Warming's work, begun in 1884, was almost neglected because published in Danish, and it was not till his *Plantensamfund* appeared in German (1896) that his influence was felt; an English edition was issued in 1909, and a new German edition (1918) extends to 800 pages, with a complete bibliography of Ecology. Recent literature includes the results of much intensive study on external form, internal anatomy, and vital function, mainly relating to the vegetative organs. A natural order in systematic botany is a group held together by features of flower and fruit common to all the species. From the ecological standpoint the recognition of growth-forms is an element of training quite as essential as the distinguishing of natural orders. The deciduous type of British tree has a growth-form distinguished by woody stems and branches bearing buds through the winter, and by summer leaves relatively broad, thin, and with a distinct upper and lower surface. Similar features characterise the deciduous trees of all temperate climates with summer rains. One growth-form of the British moorland is the short needle-like leaf on low, dwarf, woody bushes, such as the ling (*Calluna*) and its floristic relatives the bell-heaths (*Erica*); it can be recognised again in the Cowberry (*Empetrum*), which is not a true heath. The moorland and heath grasses present a growth-form with tufts of bristle-like leaves, and this is seen again in moss sedges (*Carex*, *Scirpus*, and *Eriophorum*) and rushes (*Juncus*). The floating leaves of aquatic plants, the cactus-form with fleshy stems, and the leafless, green-twigged switch form of our bloom (*Cytisus*) and furze (*Ulex*) will recall other prominent growth-forms. The first edition of Warming's *Ecology* (1895) was based on a simple classification of growth-forms; hydrophytes or water-plants, xerophytes adapted to periodic drought, halophytes living in desert or maritime saline habitat, and mesophytes with an environment where moisture is relatively constant. His later classification (1918) includes sixteen classes, mainly the result of subdividing the xerophytes. The outstanding feature is the importance assigned to water-supply, and this has had a widespread influence on subsequent work on ecology. The limits of a plant are not determined by so many inches of rainfall per annum, but by the recurrence of drought-periods which must be survived if the plant is to exist. Nor is the mere presence of water any criterion, because plant-life is determined by the availability of the water. A coastal salt-marsh is submerged by the higher tides of each month and is generally wet underfoot, but the plants are small in comparison with the tall reeds on the wet mud-banks beside a fresh-water lake. They are more like xerophytes than hydrophytes; and the reason is that the presence of excessive salts interferes with the absorption of water. Another wet area in Britain is the peat-bog, and here again the plants are xerophytes, because, though water is abundant, it is not available for plants in soils consisting mainly of humus. Peat-deposits are also liable to surface drought in summer and during periods of frost. Northern climates are especially prolific in growth-forms, and in recent ecology the investigation of these occupies a promi-

nent place. The classification by growth-form, important though it be, does not lend itself to regional survey in a country like Britain, because mesophytes and plants with xerophytic adaptations frequently occur in the same plant community—for instance, in an upland oak-wood and in some types of marsh. C. Raunkiaer, another Danish ecologist, has utilised the growth-form to express the relation between vegetation and climate. His view is that the plant itself must be the biological record of climate, and that any physical standard such as rainfall or temperature is insufficient. It has already been pointed out that physiological drought may arise from different combinations of physical factors, such as cold and actual absence of moisture. Raunkiaer's classification of 'life-forms' is into trees and shrubs (phanerophytes), dwarf plants with buds near the surface of the soil (chamaephytes), herbaceous perennials with dormant buds in the upper crust of the soil (hemipterophytes), plants with deeply buried bulbs and rhizomes (cryptophytes), and annual or once-flowering plants (therophytes). The basis of this grouping is the condition of protection of buds during the critical period. In tropical regions with a high rainfall, phanerophytes will be found to dominate if a census of the flora be made; therophytes are characteristic of deserts and highly cultivated lands; chamaephytes and hemipterophytes are the dominant groups in northern lands. (A summary of Raunkiaer's publications will be found in *Journal of Ecology*, vol. i. 1913.)

Colonisation and Succession.—The history of every plant community begins on bare soil or some other open substratum. This period may be very ancient or it may be as recent as the last ploughing of a field or the making of a railway. In Britain many habitats had their origin when hills and slopes were left bare after being eroded and cleared of vegetation by ice-action during the Glacial Period (q.v.), and the same ice-agencies left wide tracts of newly deposited soil. Through all time coasts, stream-banks, and inland cliffs have been eroded, thus exposing fresh surfaces, while the eroded material, spread out as coastal and river deposits or as cliff-screens, provides other soils. Wind-action is also a denuding and depositing agent, as on our sand-dunes and over wide areas of continental loess-soils (see GEOLOGY). Such surfaces present a wide range as regards situation, exposure, water-supply, soil-texture, fertility, &c., and these factors have a profound influence on the future vegetation. This aspect of plant ecology has received attention from the American schools initiated by H. C. Cowles and F. E. Clements, also from C. B. Crampton and C. E. Moss in Britain. The plants occupying new land pass through the phases of migration by seeds or otherwise, and settlement. There must always be considerable distribution by seeds, but colonisation will rarely succeed except where the soil is devoid of a closed plant-covering. Given the opportunity, many organisms may effect a landing, and begin life, but a sorting out will take place. Some will die as seedlings; others will leave no progeny. The survivors will include many species that can flourish only while the habitat remains open and competition is not intense. This is the case so long as the substratum is in a mobile or unstable condition, but sooner or later the water or other dynamic agent becomes ineffective, the sand-dune or coastal mud-flat becomes protected by newer deposits seawards, or the stream is forced into new channels, or the material from crags comes to rest. Thus the plant-covering evolves along with the habitat, and the vegetation itself is an important factor in the preparation of the habitat for later phases. A plant succession is the series of communities which in turn occupy the

habitat until a 'climax formation' occupies it and excludes the invasion of another dominant. The successional series leading up to a climax formation is called a 'sere' (F. E. Clements, 1916). In Britain climax formations are represented by deciduous forest (oak, beech, &c.), birch-pine forest, some grasslands such as the chalk Downs, and upland northern moors. The succession of plant communities may be more evident if a specific case is quoted—that of lowland peat-moss. These often begin their history as shallow lakes at first occupied by colonies of submerged and floating hydrophytes. Later the reed-swamp of the margin may invade the middle of the lake, and suppress the earliest colonists. Marsh plants of lower form in turn oust the reed-swamp. Then the whole may become a peat-bog with plant communities characteristic of wet peat. Still later phases may be seen—e.g. *Calluna* on dry peat, birch-wood, and finally pine-wood. That such successions have occurred in the past is proved by numerous investigations on plant remains in the peat-bogs of northern Europe and America.

Plant Ecology in Britain.—The first direct influence came from France, where R. Smith, a Scottish botanist, studied at Montpellier under Ch. Flahault, then engaged in carrying out agricultural and forestry surveys. Between 1897 and 1900 R. Smith published *Plant Associations of the Tay Basin*, and two parts of a Botanical Survey of Scotland—Edinburgh and northern Perthshire. These papers are primary or reconnaissance surveys intended to demonstrate the major plant-communities, and to outline their relation to environmental factors. The maps (scale, two miles to one inch) show types of farmland, forest, moorland, &c., over considerable areas, so that deductions may be drawn as to their distribution in relation to physiography and other factors.

The primary survey has become a conspicuous feature of British ecology, and the published material includes: West Yorkshire (W. G. Smith, C. E. Moss, and W. M. Rankin, 1903), Westmorland (F. J. Lewis, 1904), Forfar and Fife (W. G. Smith, 1905), Dublin District (G. H. Pethybridge and R. L. Praeger, 1905), Somerset (C. E. Moss, 1906), Caithness (C. B. Crampton, 1911), and the Peak District (C. E. Moss, 1913). The methods have an obvious application to agriculture and forestry. The primary surveys have formed a nucleus for more detailed investigations on special plant communities and habitats, especially on woodlands, fen, and lake vegetation. An active school of research on the ecology of coastal plants has been founded at Blakeney point, Norfolk, by F. W. Oliver, a pioneer worker on the vegetation of shingle-beaches and salt-marshes. The work done on British ecology has been conveniently systematised in text-book form in *The Types of British Vegetation*, edited by A. G. Tansley. The study has attracted the attention of many of the younger botanists, and a British Ecological Society has been formed.

Ecology has received a considerable impetus in recent years through the support of the Carnegie Institution of Washington (see the Year-books from No. 16, 1919). F. E. Clements and a number of associates have thus been enabled to carry on extensive investigations bearing on the utilisation of the western United States from the outlook of agriculture and forestry, and important publications have already been issued.

Animal Ecology.—This has advanced more slowly than plant ecology, probably because of the greater difficulty in obtaining a proper viewpoint, and in securing enough data for first principles. In zoology, as in the earlier botany, great attention has been given to the structure of individuals or genetic groups, to comparative

anatomy, and to isolated physiological phenomena, but little has been systematised as regards relation to habitat. The chief ecological effort has been made in America. Thus C. C. Adams, besides publishing numerous observations, has issued a *Guide to the Study of Animal Ecology* (1913), and V. E. Shelford, in *Animal Communities in Temperate America* (1913), has provided a model for future work in regional survey with reference to animals. The latter outlines a classification beginning with simple groups of organisms, often a single species, in full agreement as regards life-history and environment. Following on this are increasingly complex groups, including strata and associations leading to extensive formations or groups influenced by climate or topographic age of the habitat. Annual succession on a given habitat is recognised as comparable to plant succession. Considerable importance is naturally ascribed to food-relations, and charts have been prepared illustrating these. The subject is still in its infancy, but the experience gained in plant ecology is evidently being utilised with success.

The Place of Man in Ecology.—In ecological studies it generally simplifies the problem to begin on an area as free as possible from interference by man, but sooner or later this difficulty has to be met. Forest regions everywhere are more or less affected by fire, and wide areas have been exploited for timber or destroyed to make way for farmland. Grasslands in America, Africa, and Asia have been ruined since ancient times, mainly to provide food for stock and game, as are our native heather-moors to-day. Thus the ecologist soon becomes an observer of agricultural systems, forestry, game preservation, and rural economy in general. Disforestation means not only the removal of the dominant trees, but also the destruction of the whole forest community, plant and animal, except, perhaps, a few survivors adapted to the new conditions. It is probable that many miles of northern heather-moor were formerly forest supporting a forest population, but now they bear a meagre flora suited for hardy sheep, grouse, the red deer, with the scanty population dependent on these. The forest on the more fertile lowlands has given place to arable fields continuously disturbed and in a state of primary succession, or to areas maintained as grassland by continuous grazing of stock. In more congested districts new problems arise, including the colonisation of roadside and railway banks, waste heaps from mining, and other habitats directly due to man. Again, the distribution of towns and villages is largely ecological. The greater agricultural population follows the more productive soil, and the inland market-town often occupies a place where the corn-grower of the lowlands meets the wool-grower and stock-raiser of the uplands to exchange products. Problems like these can be more easily approached if general principles exist; the discovery and systematising of these is the aim of ecology.

Literature.—The following text-books are provided with full lists of literature: E. Warming, *Ecology of Plants* (1909); A. F. W. Schimper, *Plant Geography upon a Physiological Basis* (1898); F. E. Clements, *Research Methods in Ecology* (Lincoln, Nebraska, 1905) and *Plant Succession* (Carnegie Institution, 1916); A. G. Tansley, *Types of British Vegetation* (1911). New papers are published or fully reviewed in the *Journal of Ecology*.

Economics. See **POLITICAL ECONOMY**.

Economy (Gr. *oikonomia*, 'household management') is etymologically equivalent to what is usually called Domestic Economy (q.v.); Political Economy (q.v.) is the usual but somewhat inconvenient name for economics or economic science. We speak also of the vegetable economy, the animal economy, the social economy; and theo-

logically the Jewish economy is equivalent to the Jewish dispensation. Economic botany is discussed at **PLANTS** (*Uses of*).

Ecorché (Fr., 'flayed'), a figure in which the muscles are represented, stripped of the skin, for purposes of artistic study.

Ecraseur, the name of an instrument invented by M. Chassaignac, and consisting of a stem with a fine chain passed through it, which, passed round any tissues, gradually constricts them, and finally crushes its way through them by means of a screw or rack for tightening it, which is worked at the end of the handle. Other forms of the instrument are arranged for a single wire, or a cord of twisted wires, instead of the chain. The advantage of this instrument over the knife is that it causes little or no bleeding, the torn vessels spontaneously contracting and closing. It is specially applicable to pedunculated growths, such as piles and polypi, but has been used extensively in removal of the tongue for cancer. In the galvanic *écraseur* the general arrangement is the same; but the wire noose is insulated and connected with a battery, that it may be heated to redness during its passage through the tissues, and may cauterise as well as crush them. As the pain which is caused by this instrument is very great, the patient should be placed completely under the action of an anæsthetic before it is applied.

Ecstasy (Gr. *ekstasis*, 'displacement', 'trance'), a word applied to those states of mind which, without amounting to Insanity (q.v.), in respect of the temporary character of the affection, are marked by mental alienation, and altered or diminished consciousness. The varieties of this affection are infinite. In some physical states, as catalepsy, hysteria, mesmerism, a true ecstasy is one of the phenomena, inasmuch as the proper consciousness of the individual is temporarily abolished, or so much changed in character as to lead almost to the loss of the sense of personal identity; and probably the same may be said of the mind in many dreams and visions, and also in somnambulism. Religious ecstasy, in which a man, 'being withdrawn from the senses, is raised to the contemplation of supernatural things,' and may receive the beatific vision, has been recorded of very many modern saints, notably St Teresa. It is represented as accompanied by such phenomena as being raised several feet from the ground (St Philip of Neri, St Ignatius, &c.), and bilocation or double personality. It might be produced by diabolic agency as well as by God. For the literature of the subject, see **CANONISATION**; and see **CONVULSIONARIES**, **DANCING MANIA**. The word ecstasy is loosely used for paroxysms of love, fear, hate; and it has a special sense in the philosophy of Neoplatonism (q.v.).

Ecthy'ma is a pustular disease of the skin, in which the pustules often reach the size of a pea, and have a red, slightly elevated, hardish base. In the course of two or three days after the appearance of the pustule it is replaced by a scab, which adheres firmly to the base, and is somewhat concave. On its removal, a deep red mark, a new scab, an ulcer, or a healed scar remains. The disease may be acute or chronic. The acute form is ushered in by slight constitutional, not amounting to febrile, symptoms, and by a burning or pricking pain at the seat of the eruption, which is most commonly the back and shoulders. The disease runs its course in ten days or a fortnight. In chronic ecthy'ma, the pustules which follow in crops (often for several months) are usually scattered over the extremities. This form of eruption indicates a low state of the system. It sometimes follows the acute disease, and not infrequently is a tertiary symptom of syphilis. Pustules, which

in no respect seem to differ from those of ecthyma, are produced by various local irritants. Thus the affection of the hands popularly known as *the grocer's itch* is produced by the irritation of brown sugar, perhaps by the *acar* which are so often present in it. Stone-masons are said occasionally to suffer from a similar disease. With regard to *treatment*, the acute form would in most cases doubtless disappear in the course of a fortnight if left entirely to itself; but as the bowels are usually disordered, an occasional alterative aperient, as a few grains of gray powder with a little rhubarb, may be prescribed, and tepid water applied locally gives great relief. The patient should, moreover, be kept on a moderately good, nutritious diet. In the chronic form of the affection a liberal diet is necessary; the use of wine or porter is sometimes desirable; while tonics, such as a combination of bark and nitric acid, are called for. Tepid baths are often useful, and if there is sleeplessness, an opiate should be taken at or shortly before bedtime.

Ectoderm, or EPIBLAST, the external germinal layer of the embryo, giving rise especially to the outer skin, nervous system, and the essential parts of the sense organs in the adult. See EMBRYOLOGY.

Ectozaa, external parasites—e.g. lice, ticks, various crustaceans. See PARASITIC ANIMALS.

Ectropion (Gr., from *ek*, 'out,' and *trepō*, 'I turn'), eversion of the margin of the eyelid, so that the red inner surface (conjunctiva) is exposed. It is generally caused either by chronic inflammation of the conjunctiva, or by scars in the skin near the eye, following wounds, burns, or disease. It is the converse of entropion, and, like it, usually requires an operation for its cure. Recent and slight inflammatory cases, however, may yield to milder measures.

Ecuador, a republic of South America, so named from its position on the equator. Its general outline is cuneiform; bounded on the west by the Pacific, it is inserted like a wedge between Colombia and Peru. It has a seaboard of some 400 miles. Most of the frontier east of the Andes was long disputed, and no two maps agreed in the limits they assigned to the state in this direction. In 1832, however, Colombia's claims to the plateau of Pasto were recognised, and since 1876 the same state has held the river Putumayo; and by the treaty of 1917 Ecuador is now separated from Colombia on the north-east by the watershed between the Putumayo and the Napo. The whole of the Marañon valley is occupied by Peru, but the Peruvian frontier is still disputed. Thus narrowed, the territory of the republic embraces some 100,000 sq. miles, or about half the area of Spain, and barely two-fifths of that usually claimed for it. The state consists of 17 provinces and the territory of Colón—that is, the Galápagos Islands (q.v.), which have an area of 2400 sq. miles. The population was estimated in 1920 at 1,500,000, of whom 400 belonged to the Galápagos. The savage and heathen Indians (*Infieles*) of the east are estimated at from 100,000 to 150,000, but their number is really unknown. The principal cities are Quito, the capital (100,000 inhabitants), Guayaquil, the chief port (100,000), Cuenca (50,000), Riobamba (25,000), Latacunga, and Ambato, the last three names associated with earthquakes of unusual force; good authorities, however, question the accuracy of the returns of population.

Ecuador may be regarded as consisting of three divisions—the lowlands west of the Andes, the mountainous plateau of the interior, and the less elevated forest-country to the east. Besides the main range of the Andes, forming the backbone of the country, there is an outer range extending for

about 40 miles, with peaks rising to 15,000 feet; from the cordillera proper numerous long spurs, attaining a height of 14,000 feet, are thrown out towards the east, between which rise great affluents of the Amazon, while the coast-range possesses only short and very precipitous spurs, contributing to the comparatively unimportant Pacific streams. The plateau is cut up by short and broken cross-ridges; on one of these tablelands lies Quito. For the heights of the principal peaks, see **ANDES**; but it should be noticed that the parallel structure commonly ascribed by geographers to this section of the cordillera has hitherto had an exaggerated importance attached to it, and, as a matter of fact, scarcely exists. The principal mountains of Ecuador either are or have been volcanoes. Tunguragua (16,690 feet) broke out in 1887; Pichincha is by no means extinct; Cotopaxi (q.v.) and Sangai (17,465) are constantly active. In mineral wealth Ecuador has been ranked amongst the poorest states of South America; gold, however, is obtained in the beds of the Amazonian tributaries, and the ore is mined at Zauma, in the south-west; emeralds, silver, quicksilver, iron, lead, platinum, copper, zinc, salt, asphalt, sulphur, and petroleum occur, as well as an inferior graphite, and fine veins of anthracite have been found in the mountains. Of the coast-streams the principal are the Guayas, or Guayaquil River, and the Río Esmeraldas; east of the Andes the most important rivers are the Napo, with its affluents the Curai and Coca, the Tigre, and the Pastaza, all flowing into the Marañon. It is estimated that at least 2500 miles of the river-system on the Amazon side are suitable for steamboat navigation, and probably as much more for boats, besides some 500 miles on the western side.

Ecuador is an agricultural country. The dry winds which leave the African coast become saturated as they pass over the Atlantic and up the Amazon; and their moisture is almost ceaselessly precipitated as they approach the snowy peaks of the Andes, producing a dense growth of vegetation on the eastern foot-hills. On the other side also, where the rain-clouds of the Pacific are caught, the gorges of the western spurs become very hot-houses, and most of the land is covered with dark-some forest. Natural *savannas* or open plains are, however, found on the western lowlands, such as are not met with to the east. Here, in the most prodigal luxuriance of tropical vegetation, valuable trees and plants wage endless war for existence against the stifling embraces of mosses, orchids, parasites, and creepers. With increasing elevation, the sugar-cane *haciendas* and the cacao and orange groves give place to fields of inferior wheat, barley, clover, lucerne, beans, and in some places maize and agave plants, until in the higher stretches of the sierra nothing is met with but lichens and the bare páramo grass. The agricultural implements employed are often of the rudest, including in the mountains wooden ploughs, and in the lowlands the *machete* or cutlass; American machinery, however, is imported for the sugar-mills. Sarsaparilla, balsams, rubber, vegetable ivory and wax are collected, and coffee, rice, cotton, tobacco, &c. are grown, but in smaller quantities; while the trade in cinchona, for which bark the world was first indebted to the province of Loja, promises soon to be a thing of the past, owing to the reckless destruction of the trees. The coast rainy season usually extends from December to May, but on the Amazon slope, as already noticed, it rains nearly all the year round. The plateau region and large tracts to the east are comparatively healthy, in spite of the absence of all sanitary measures in the towns and wretched villages; the valleys on the Pacific side

are commonly full of disease. In the interior there is a very small thermometric range, and in temperature a perpetual spring reigns in the uplands; to which much-admired equality of climate, which renders it certain that to-morrow will be like to-day, the incomparable laziness and procrastination of the Ecuadorians has been attributed. The fauna is rich: the mammalia include the jaguar, puma, ounce, ocelot, deer, tapir, peccary, capybara, and several species of monkeys and bats; fish abound, both in the rivers and along the coast; and among reptilia are the boa constrictor, turtles, and alligators, which swarm in the streams, especially on the Pacific side. Chiefly, however, is Ecuador the paradise of birds and insects. The former range from the condor to the humming-bird, and include parrots, partridge, pheasants, snipe, wild turkeys, geese and ducks, herons, and pigeons, as well as the flute-bird and many other song-birds; of the insects and arachnida, besides butterflies innumerable, mosquitoes, scorpions, the tarantula spider, the microscopic 'red tick,' and the maddening Pium-fly are met with, whilst a traveller in the sierra has remarked emphatically that there 'every kind of domestic insect pest known in England exists with the addition of further infinite varieties.' The live-stock includes cattle, sheep, horses, mules, donkeys, and llamas; but cattle do not thrive in the Amazon section—chiefly, perhaps, from the immense number of bats which bleed or otherwise irritate them.

The whites have been estimated, in round numbers, at 100,000 or 150,000, the mixed races at 500,000; the rest are pure Indians, with a small proportion of negroes. The whites, who are the landholders and merchants of the country, are hospitable, courteous, and generally intelligent, but extravagant and innocent of habits of industry; they form a governing class. The half-breeds are the true savages of the country, the Christianised Indians, who belong to the Quichua group, being as a class docile and contented, although till 1918 the law which permitted the Indian who could not otherwise satisfy his creditor to sell himself into slavery reduced great numbers to the unhappy conditions of serfs. The uncivilised tribes inhabit the vast region to the east of the Andes; their chief stems are the independent and warlike Jívaros and Záparos. All religions are now (since 1904) on an equal footing. Till then the state religion was Roman Catholic. The hierarchy includes an archbishop of Quito and six bishops. In no country in the world have the Jesuits had such a paramount influence as in Ecuador, or employed it, on the whole, so well. There are numerous convents, monasteries, and seminaries. Education is compulsory, but still at a low ebb. Quito, however, possesses a university (18th century) and an institute of sciences (1884), and there are universities at Cuenca and Guayaquil, and a college of law at Loja. Public instruction, considering the difficulties the government has had to grapple with, has made creditable headway, hundreds of primary schools, in particular, having been established throughout the country. Technical schools and literary societies also have been founded. The manufactures are sugar, beer, chocolate, timber, coarse cloths, kerosene, ice, spirits from the sugar-cane, and flour or starch from the yuca or cassava root. Guayaquil is famed for its hammocks and Panamá hats, made from the fibre of the 'pita' plant (see AGAVE, CYCLANTHACEÆ). Commerce is sadly handicapped by the want of roads. About 400 miles of railway are open, but there are 4400 miles of telegraph, as well as wireless installations, and there are telephones in Guayaquil, Quito, and elsewhere. A few steamers are in use, but around Guayaquil rafts also are much

employed to-day as in Pizarro's time; and, generally, communication is carried on by means of tracks almost impassable in the rains, and goods are conveyed by mules. East of the cordilleras, moreover, the line of route is often not marked even by bare tracks; the road must be forced through pathless forests, along the rough beds of rivers, and over swollen streams, either bridgeless, or spanned by such flail erections as existed when Humboldt visited the country. Nearly two-thirds of the exports, of which the principal are cocoa, vegetable ivory, coffee, hats, hides, and rubber, come through Guayaquil. The imports from Great Britain are chiefly cotton goods.

Constituted as an independent state on the dissolution of Bolívar's Colombia (q.v.), the Republic of the Equator has passed through a succession of violent political changes that would render its history equally difficult and profitless to follow; in his report to congress in 1888 the Minister of the Interior sorrowfully confessed 'our historical tradition is—revolution'. The turbulent career of the despotic little republic, with its complicated series of presidents, supreme chiefs, provisional commissioners, and dictators, has been almost one long insurrection, amid which the nearly equally constant loss of territory has passed unheeded by the factions and their leaders. Under its constitution of 1906 the executive is vested in a president, elected for four years, with a cabinet of five ministers, and a council of state; the legislative power is entrusted to a senate and house of representatives, elected by male citizens who can read and write. There is no vice-president. The state forms six military districts, containing seventeen provinces, which are administered by governors, and subdivided into cantons; and one territory. The standing army numbers some 5000 or 6000. Military service was made compulsory in 1921. There is a navy of three vessels. Of the financial position of the country it has always been difficult to obtain exact and trustworthy information, although evidence has at all times been forthcoming of its chronic and apparently hopeless embarrassment. The expenditure sometimes considerably exceeds the revenue. The liabilities of the republic are heavy, even disregarding unpaid interest; from time to time it is announced that the country is not yet in a position to make any practical offer to its foreign creditors.

Ecumenical, from Gr. *oikoumenikos*, 'of' or 'from the whole earth'—*oikoumenē* (*gē*) meaning 'the inhabited (world)'—is a term applied to the general councils of the universal church from that of Nicaea onwards (see the article COUNCIL). The 'Apostles' Creed, the creed of Nice and Constantinople, and the creed of Athanasius are distinguished as the 'ecumenical symbols' of the Christian church. Though the title 'Ecumenical Bishop' was one that originally in the Eastern church might be applied to any patriarch, yet Pelagius II. and his successors in the Roman see persistently protested against its being given in imperial documents to the patriarchs of Constantinople, who had adopted it since 587.

Ecze^ma (Gr., from *ekzeō*, 'I boil over') is in this country by far the commonest of all diseases of the skin, and also the most variable in its manifestations. It may be acute or extremely chronic, may affect any portion of the skin, and may occur at any age from infancy to old age.

In typical acute eczema the affected portion of skin is red, and is covered with numerous small papules, which speedily turn into vesicles. These may quickly dry up, but more commonly break, and discharge a clear, glutinous secretion, which hardens and forms scabs or crusts, or if copious keeps the surface in a moist 'weeping' condition. In some cases the vesicles are replaced by pustules, and the discharge is partly purulent. Chronic eczema may follow the acute form, or may arise without an acute stage. Here the skin is thickened and hard, and covered with crusts or scales; deep cracks are sometimes present, especially where the skin is subjected to much movement, as near the joints.

One of the most prominent and important symptoms is itching of the part affected; it is never entirely absent, and in some cases intolerably severe, but in the acute stage is often replaced by a burning sensation; it may precede any visible sign of the disease, and may persist after the skin has resumed its natural appearance. The scratching which it occasions always aggravates the disease, and is often very difficult to prevent. Except in extensive acute attacks, there is no fever and very little constitutional disturbance. The disease is not contagious. When cured it leaves no scar.

Causes of Ecze^ma.—In many cases it is very difficult, perhaps impossible, to assign a definite cause for an attack. Generally speaking, however, the constitutional or predisposing cause is some defect in the digestion or assimilation of the food; diabetic and gouty individuals are particularly subject to the disease. The local or exciting cause may be anything whatever which irritates the skin—e.g. great heat or cold, rough underclothing, handling of certain plants—e.g. the Chinese primrose, bad soap, hard water, arsenical dyes, lice or other parasites, and the scratching they occasion.

Treatment.—There is no specific for eczema; different cases and different stages of the disease require widely different management. Usually both local and constitutional treatment are required to effect a cure. It is of the greatest importance to seek for and attend to any cause which may have given rise to it. The diet must be nutritious, but as simple and unirritating as possible; digestion may require aid from medicines; the bowels should be regularly evacuated, by aperients if necessary; a gouty or any other unhealthy tendency must be counteracted. In obstinate chronic eczema small doses of arsenic are often useful. The use of soap on the part affected must be discontinued, and strained oatmeal gruel, or rice water, or white of egg with boiled water, used for cleansing purposes, but even these as seldom as possible. Thorough removal of scales and crusts by these means, or by oil, or simple bread poultices, is the necessary preliminary to satisfactory local treatment. In the acute stage, where the swelling is great or the discharge profuse, a sedative lotion applied on lint and kept moist by a waterproof covering is generally most useful—e.g. thin starch with a teaspoonful of boracic acid to the pint, soft water with a similar proportion of baking-soda, or dilute lead lotion. In the later stages, when the skin is moist, soothing ointments are preferable—e.g. zinc ointment, zinc and boracic ointments mixed in equal parts, or Lassar's paste, consisting of 10 grains of salicylic acid, 2 drachms of starch, 2 drachms of zinc oxide, and half an ounce of vaseline. The ointment should

be evenly spread on linen rag, and kept in close contact with the affected skin. If dry chronic forms do not yield to similar treatment, tar ointment should be cautiously tried; but they sometimes require the use of a strong irritant, as a solution of caustic potash.

Edam, a town in North Holland, 13 miles NNE. of Amsterdam. Its specialty is cheese. Pop. 5000.

Edar (IDAR), a Rajput state of Guzerat in the Mahi Kantha agency within the boundary of the presidency of Bombay, is under a maharaja. Area, 1668 sq. m.; pop. 226,000, mostly Hindu. Its capital is Almadnagar (pop. 4000), which has superseded Edar, some 12 miles farther north.

Edda (etymology unknown), the name of two very different collections of old Scandinavian literature. Of these the 'Younger' or prose *Edda* was written by the Icelander Snorri Sturluson (q.v.) about 1230, and was discovered by Arngrim Jónsson in 1628. It consists of three parts: (1) *Gylfaginning* ('the deceiving of Gylfi'), mythological stories told by Odin to Gylfi, a Swedish king, forming the chief source of our knowledge of the Scandinavian theogony; (2) *Skaldskaparmál*, or the Art of Poetry; and (3) *Háttatal*, a system of prosody. Prologues and epilogues are added by later hands. The work contains quotations from about seventy early poets. It is found in three great MSS.—the *Codex Riegii* (about 1300), discovered by Brynjulf Sveinsson in 1640; the *Codex Wormianus* (about 1330), so called because it was sent to Ole Worm in 1628; and the *Codex Upsalensis* (about 1300), where the name 'Edda' first occurs. Editions of the prose Edda were published by Resenius (Copenhagen, 1665), Rask (Stockholm, 1818), and Egilsson (Reykjavik, 1848). The most complete is that of the Ane-Magnæan commission (3 vols. Copenhagen, 1848-87), with Latin translation and notes. Finnur Jónsson edited both Eddas, with German notes (1890-90). There is an edition of *Háttatal* by Möbius (Halle, 1879-81); and Bergmann (1861) furnishes a French translation of *Gylfaginning*, with prolegomena and critical commentary. There are English translations by Dasent (1842), R. B. Anderson (a selection, 1880), and A. G. Brodcur (1916).

The 'Elder' *Edda* is a collection of lays which contain legends of Scandinavian gods and heroes, and are productions mainly of Iceland, and of different periods from the 9th to the 11th century. It was discovered about 1643 by Brynjulf Sveinsson, who applied the name 'Edda' to this collection also, which he attributed to Semund Sigfusson (who lived in Iceland about 1055-1132). The poems belonging to the Elder Edda are thirty-three in number, with prose passages interpolated here and there by the collector. They are on subjects partly of Scandinavian mythology, partly of heroic and legendary history. A few of the latter are derived from legends purely Scandinavian, the remainder treat of heroes common to the Teutonic races. They are written in two forms, distinguished as *kviðuháttir* (epic metre) and *ljóðháttir* (didactic metre). The first of these consists of strophes of eight lines, every two of which are connected by alliteration, each line having two (usually two-syllabled) feet, with an accent on each foot; the alliterative initial sounds in the accented syllables being regularly three in number—two in the first, and one (the most emphatic of the three) in the second of each pair of lines, as in Old English poetry (see ALLITERATION). The peculiarity of *ljóðháttir* is that in its strophe (*Versu*) has regularly only six lines, of which the first, second, fourth, and fifth are constructed exactly as in the other form (i.e. they have

two accents, and are connected in pairs by alliteration. The third and sixth lines, however, have each three accents and alliteration of its own, the alliterating sounds in each of these lines being two (sometimes three) in number, and different from those in the two preceding it. The collection now called the *Elder Edda* was unknown to Snorri, yet almost all the lays are paraphrased or quoted by him in his own work from the oral tradition of his time. The earliest complete editions were those of the *Anne-Magnæan* commission (3 vols. Copenhagen, 1787-1828), Rask (Stockholm, 1818), and Munch (Christiania, 1847), which were followed by those of Luning (Zurich, 1859) and Möbius (Leip. 1860). Those were superseded by Bugge's edition (Christiania, 1867), on which those of Grundtvig (2d ed. Copenhagen, 1874) and Hildebrand (Paderborn, 1876) are based, now embodied in Vigfusson and Powell's *Corpus Poeticum Boreale* (2 vols. Oxford, 1883). Later editions are Neckel's *Edda* (1914) and Miss Martin Clarke's *Havamal* (with translation, 1923). There are English translations by Thorpe (1866), R. B. Anderson (Chicago, 1879), and Olive Bray (with text, 1909), H. A. Bellows (with introduction and notes; New York, 1923).

Eddington, ARTHUR STANLEY, astronomer, born at Kendal, 28th December 1882, studied at Manchester and Cambridge, became first assistant at Greenwich (1906) and professor at Cambridge (1913). His writings deal with relativity and gravitation.

Eddoes. See COCCO.

Eddy, MRS. See CHRISTIAN SCIENCE.

Eddystone, a group of gneiss rocks, daily submerged by the tide, in the English Channel, 9 miles off the Cornish coast, and 14 SSW. of Plymouth Breakwater. The rocks lie in 50° 10' 54" N. lat., and 4° 15' 53" W. long., and have 12 to 150 fathoms water around. The frequent shipwrecks on these rocks led to the erection of a lighthouse on them by Winstanley, 1696-1700. It was

The New Eddystone Lighthouse.

a wooden polygon, 100 feet high, with a stone base; but the great storm of 20th November 1703 completely washed it away, with the architect. Another lighthouse was built, 1706-9, also of wood,

with a stone base, and 92 feet high, by Mr Rudyerd, a silk-mercator. This erection was burned in 1755. The next, noted for its strength and the engineering skill displayed in it, was constructed by Smeaton in 1757-59, on the model, it is said, of the trunk of the oak-tree. It was built of blocks, generally one to two tons weight, of Portland oolite, incased in granite. The granite is dovetailed into the solid rock, and each block into its neighbour. The tower, 85 feet high, had a diameter of 26½ feet at the base, and 15 feet at the top. The light, 72 feet above the water, was visible at a distance of 13 miles. As the rock on which this tower was built is undermined and greatly weakened by the action of the waves, the foundation of another was laid on a different part of the reef in 1879. The new lighthouse, completed in 1882 by Sir James N. Douglass, F.R.S., is, like its predecessor, ingeniously dovetailed throughout. Owing to the state of the foundation, Smeaton's lighthouse was taken down to the level of the first room as soon as the new one was completed. The removed upper portion was re-erected on Plymouth Hoe, while the lower portion, as shown in the picture, remains intact. See LIGHTHOUSE.

Edelinck, GERARD, a celebrated engraver, born at Antwerp in 1649, died in Paris in 1707. He was patronised by Louis XIV., taught the Gobelins tapestry-workers, and produced over 420 plates. See ENGRAVING.

Edelweiss (*Leontopodium alpinum*) is a small but pretty composite found growing in damp places at considerable altitudes (5000 to 7000 feet) throughout the Alps. Its characteristic appearance, due to a covering of long white woolly hairs, is not unfamiliar in English rock-gardens. It became an article of minor commerce, dried as a book specimen made up into little tufts, so that measures were found necessary in Switzerland to prevent its total extirpation from its native haunts. It can be cultivated without much difficulty, and can be seen in many collections of Alpine Plants (q.v.).

Eden, the name given by the Old Testament to the garden or Paradise in which Adam and Eve lived before the Fall. It is described in Genesis ii. 8-15 as a particularly fertile region, containing every tree that is pleasant to the sight and good for food. Many attempts have been made to identify the locality in which Eden was situated. The only assistance which the Old Testament affords us is the description of the river which watered Eden, and its tributaries. After flowing through the garden, the river was parted and became four heads. The names of these four heads are Pishon, Gihon, Hiddekel, and Euphrates. Hiddekel is generally identified with the Tigris. There is much more difficulty about the identification of the other two rivers—the Pishon and the Gihon. The connection which seems obviously to exist between them and the Euphrates and Tigris suggests that they are two tributaries of these rivers, and this is the view that is commonly adopted, though diversity of opinion exists as to their exact counterparts in modern geography. If this theory be deemed satisfactory, the site of Eden must be placed in Babylonia, near the confluence of the Euphrates and the Tigris. Further corroboration of this view is often found in the fact that the plain of Babylonia is called in the Sumerian language *Edenu*—a name which at once suggests Eden. There are two serious difficulties about this theory: (1) There are no rivers as important as the Euphrates and the Tigris which we can identify with the Pishon and the Gihon; (2) the description of the countries through which the Pishon and the Gihon flowed is difficult to reconcile with this hypothesis. The Pishon is described as the river which 'compasseth the whole land of Havilah.'

The term 'Havilah' is used to describe the 'sandy desert' of North Arabia, which extends from Ophi to the neighbourhood of Edom. According to Genesis, Gihon 'compasseth the whole land of Cush,' and the term Cush is usually applied to Ethiopia. From the time of Josephus there has been an unbroken stream of tradition which identifies the Gihon with the Nile. There seems to be less justification for another tradition, also preserved by Josephus, which makes the Pishon equivalent to the Ganges. Those who are anxious to maintain the Babylonian site of Eden urge: (1) That Cush and Havilah need not be used here in their later sense. There is evidence to connect the former name at any rate with Babylonia. (2) We are dealing with prehistoric times, when the configuration of the country was different, and the Persian Gulf extended 80 miles farther inland than it does to-day. Possibly the Persian Gulf, which was originally regarded as a river, may be identified with the Pishon. (3) Possibly there was a Semitic myth which regarded Babylonia as the source of all the important rivers of the world.

Other theories as to the locality of Eden: (1) in the extreme north-east, towards the Altai Mountains (Josephus); (2) in Armenia, between the sources of the Euphrates and Tigris (Bunsen, Keil); (3) in Chaldea (Calvin); (4) in the neighbourhood of Damascus (Le Clerc); (5) in Udyāna, near Kashmir (Renan).

There are similar myths in Babylonian and Indian literature.

Eden, a river rising in the east of Westmorland, in the Pennine Chain. It runs north-north-west through the east of Westmorland and Cumberland, past Appleby and Carlisle, and ends in a fine estuary at the upper part of the Solway Firth, after a course of 65 miles. There is another Eden in Sussex and Kent, a third in Fifeshire, and a fourth in Berwickshire.

Eden, RICHARD (c. 1521-76), translator and compiler of geographical and other works, born in Herefordshire, studied at Cambridge under Sir Thomas Smith. He was dismissed for heresy from the English treasury of the Prince of Spain.

Eden, WILLIAM. See AUCKLAND.

Edenhall, the ancient seat of the Musgraves in Cumberland, 4 miles NE. of Penrith, now a school. On the famous 'Luck of Edenhall,' an old painted glass goblet said to have been snatched from the fairies, the welfare of the house depends. It is supposed to have been a chalice, and its leathern case bears the sacred monogram. Uhland's well-known ballad, *Das Glück von Edenhall*, has carried its fame beyond the British Islands.

Edentata (Lat., 'toothless'), a primitive order of placental mammals, probably including at least two distinct orders—(a) the New World Sloths (q.v.), Ant-eaters (q.v.), Armadillos (q.v.), and extinct types like Megatherium (q.v.) and Glyptodonts; (b) the Old World Pangolins (q.v.) and Aard-varks (q.v.). Almost the only general characters that can be given concern the teeth. These are quite absent in ant-eaters, and rudimentary in pangolins. In the other types they are uniform, usually simple, without roots, with no more than hints of enamel, and never present in the front of the mouth.

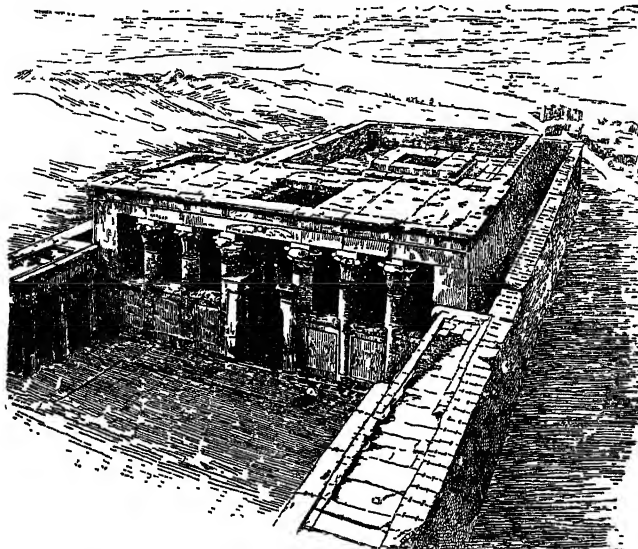

Edessa, earlier known as Aigai, was, till superseded by Pella, the capital of ancient Macedonia, and continued long afterwards to be the burial-place of the Macedonian kings. Little remains of the city, whose site is occupied by Vodena (q.v.).

Edessa (Arabic *Er-Ruha*, called by travellers *Urfa*), a very ancient city, fabled to have been founded by Nimrod, in the north of Mesopotamia,

between Aleppo and Diarbekir, 78 miles SW. of the latter town. Of its early history we know little, but with the conquest of Persia by the Greeks the history becomes less obscure. Seleucus, in particular, is said to have done much for the improvement of the city. Christianity was introduced into Edessa at an early period. In the reign of Trajan, the city was made tributary to Rome, and in 216 A.D. became a Roman military colony, under the name of *Colonia Marcia Edessenorum*. During this period, its importance in the history of the Christian church continued to increase. More than 300 monasteries are said to have been included within its walls; it was the seat of Ephraem Syrus (q.v.) and his school, and played an important part in the Arian and other controversies. Here, moreover, the famous portrait of Christ, supposed to have been painted by St Luke, and sent by the Saviour himself, with a letter, to Abgar (q.v.), king of Edessa, was preserved, till it was carried in 944 to Constantinople, and thence to the church of St Bartolomew in Rome. Edessa was conquered by the Moslems in the seventeenth year of the Hegira, 638 A.D. Christianity declined, and wars at home and abroad during the khalifate destroyed much of its temporal splendour and prosperity. It was long held by the Arab tribes of Hamdān and 'Okeyl. The Byzantine emperors succeeded in recovering Edessa for a time in 1031, but the Seljuk Sultan, Melik Shah, retook it in 1086. There was always a strong Christian element in the population, and it was due to this that the city opened its gates to Baldwin, the brother of Godfrey of Bouillon in 1097, who made it the capital of a Latin principality and the bulwark of the kingdom of Jerusalem. Under the Frankish princes, Edessa held out valiantly against the Mussulmans, till at length 'Imād-ed-dīn Zengi, ruler (*atabeg*) of Mosul, succeeded after a siege of a month, and several unsuccessful assaults, in taking the town and citadel in the year 1144, when the conqueror was so struck with the beauty and magnificence of the city that he withheld his men from sacking it. An attempt, however, of the Christian section of the inhabitants to betray the place to Joscelin in 1147 brought about the ruin of Edessa; the Christians were defeated by Nūr-ed-dīn; the city was laid waste; and all who were not massacred were sold as slaves. In 1182 Saladin added Edessa to his already extensive empire, and it was passed on to his kinsmen. After many vicissitudes, in the course of which Edessa fell successively into the hands of sultans of Egypt, Mongol emperors, Turkomans of the White Sheep, and Persian shahs, the city was finally conquered by the Ottoman Sultan, Selim I., in 1515, and has ever since formed a portion of the Turkish dominions. It now contains perhaps 40,000 inhabitants. The large Armenian Christian population has been much reduced by massacre; the rest are Turks, Arabians, Kurds, and Jews. Edessa has numerous mosques and bazaars; manufactures of cotton and silk goods, goldsmiths' wares, and morocco leather, and a large trade in corn, wool, horses, &c. Easterns, to whom it is the residence of Abraham, regard it as a sacred city.

Edfu (Coptic *Atbō*, Egypt. *Teb*, Lat. *Apollinopolis Magna*), a town of Upper Egypt, is situated on the left bank of the Nile, in 24° 56' N. lat., and 32° 53' E. long. It contains the remains of two temples, the larger of which is the best preserved monument of its kind in Egypt. It was founded by Ptolemy IV Philopator rather more than two centuries before Christ, and added to by his successors down to Ptolemy XIII Dionysus, a period of 170 years. The general plan of the temple resembles that of Dendera (q.v.). Its length is 451 feet, the breadth of its façade is 250 feet. Its

entrance is by a gateway 50 feet high, between two immense truncated pylons, 37 feet wide at the base, and 115 feet high, the whole surface covered with sculptures and inscriptions in low relief. This splendid façade is visible from a great distance, and is one of the most commanding sights in the Nile valley. Passing through this entrance, a court is reached; it is 161 feet long, and 140 feet wide, inclosed by a splendid colonnade of 32 columns of every variety of capital, and surrounded by walls, between which and the pillars there is a stone roof, forming a covered portico. The interior of this

View of the Temple at Edfu, from the top of the pylon.

court was to a great extent filled up with rubbish, and occupied by wretched dwellings, many of which also were built upon the roof of the temple; but these were all cleared away by Mariette in the khedivate of Ismail, and now the effect of the whole is grand and imposing, impressing the mind with the harmony and beauty of the design. From this court opens a hypostyle hall of 18 columns, joined by an intercolumnar screen, through which access is obtained to an inner hall of 12 columns, leading to the sanctuary, where a great monolith of gray granite was evidently intended to encase the hawk, the sacred emblem of Hor-Hud, the local Horus (q.v.), to whom the temple was dedicated. The sanctuary and surrounding chambers, together with the outer and inner halls, are separated by an open corridor from the outer wall of the temple, and both sides of this passage are covered with elaborate but monotonous reliefs and numerous inscriptions which present a sort of encyclopedia of ancient Egyptian geography, ritual, and ecclesiastical topography, with calendars of feasts, lists of divinities in the various names and cities, and even a species of church directory, including the names of singers and other temple officials. The smaller temple, erected by Ptolemy Physcon and Lathyrus, consists only of two chambers. Edfu has at present a population of about 20,000. Its manufactures are blue cotton cloths, and earthenware similar to the ancient Egyptian pottery.

Edgar, king of Scotland (1097-1107), born in 1072, son of Malcolm Canmore, fled to England from Donald Bane (1093). See SCOTLAND.

Edgar, or EADGAR, king of the English from 959 to 975, was born in 944, the younger son of

Edmund the Magnificent. After his elder brother's accession to the throne, Edgar in 957 was made ruler over Northumbria and Mercia, and two years later, on his brother Eadwig's death, became king of Wessex in addition. His reign, the policy of which was largely shaped by Dunstan (q.v.), was one of almost unbroken peace and prosperity; the Danes were conciliated, the monastic system was reformed, and the laws were strictly administered. Thus the epoch of Edgar the Peaceful was one which greatly favoured the work of national consolidation, the fusing together of the Danish, Saxon, and Mercian elements existent in the country.

Edgar the Atheling, grandson of Edmund Ironside, was born probably before 1057 in Hungary. His life may be epitomised as a series of abortive attempts. Selected by Edward the Confessor as his prospective heir, he was kept out of the throne by William the Conqueror (1066); having twice engaged in the northern revolts against the Norman, he was twice compelled to take refuge in Scotland, with Malcolm Canmore, who married Edgar's sister Margaret; then, embracing the cause of Robert, Duke of Normandy, against William Rufus, he was driven away (1091) from the duchy to Scotland; then he embarked (1099) in a bootless crusading expedition to the East; and finally was taken prisoner at Tenchebrai (1106) fighting for Duke Robert against his brother Henry I. Almost the only successful achievement of his life seems to have been that of reseating his nephew Edgar on the throne of Scotland (1097), which had been usurped by Donald Bane. His last days were spent in obscurity; the date of his death is not precisely known.

Edgehill, a hill-ridge on the border of Warwick and Oxford shires, 14 miles SSE. of Warwick. A tower, erected in 1760, marks the scene of the first great battle of the Civil War, which was fought on Sunday, 23d October 1642, between 12,000 royalists under Charles I. and 10,000 parliamentarians under the Earl of Essex. It was the intention of Charles, who had been lying at Shrewsbury, to march upon London; and Essex, who had thrown himself into Worcester, marched forward to intercept him, and entered the Warwickshire village of Kineton on the evening of the 22d. Next morning, the royalist army was discovered a little in advance, and drawn up in order of battle on the elevation of Edgehill, 3 miles to the south-east. The king's forces had the advantage in numbers and in cavalry, as well as in position; Essex, however, had the more formidable train of artillery. The royalists began to descend the hill about two o'clock, and Prince Rupert, who led the right wing, charged with his cavalry the left wing of the parliamentarians, broke it, and pursued it to Kineton. This was the fatal movement of the day. The right wing of the parliamentarians had charged and recharged with the greatest success, until, after some stubborn fighting around the royal standard, the royalist infantry broke and retreated toward the hill, and Rupert's cavalry were not available. The result was indecisive, the royalist loss being heaviest, but the advantage on the whole was with the king's forces.

Edgewater, a former village of Staten Island, since 1897 has been included in Richmond Borough of New York City.

Edgeworth, HENRY ESSEX, the 'Abbé Edgeworth,' was born in 1745. His father then was the Protestant rector of Edgeworthstown, but three years later turned Catholic, and, quitting Ireland, settled at Toulouse. There and at the Sorbonne young Edgeworth was trained for the priesthood; at his ordination he assumed the surname De Firmont from Firmount, the family property. Having declined preferment in Ireland that he might continue to minister to his countrymen in Paris, in 1791 he became confessor to the Princess Elizabeth, in 1793 to her brother, Louis XVI., just sentenced to death. He bravely attended him to the very foot of the scaffold; but the 'Son of St Louis, ascend to heaven,' was an invention, it seems, of the journalist Lacretelle. After many escapes he got safely to England (1796), and presently became chaplain to Louis XVIII. at Mitau, where he died of a fever, caught attending French prisoners, 22d May 1807. See his *Memoirs* by C. Sneyd Edgeworth (1815), and his *Letters* (1818).

Edgeworth, RICHARD LOVELL, Miss Edgeworth's father, was born at Bath, 31st May 1744. He came of a family that for 160 years had been settled in Ireland, at Edgeworthstown, County Longford. After nine years' schooling at Warwick, Drogheda, and Longford, then five months of dissipation at Trinity College, Dublin, in 1761 he was removed to Oxford, where, as a gentleman-commoner of Corpus, he passed two 'delightful, profitable' years. At Blackbourton, 14 miles distant, lived a friend of his father's, Paul Elers, a squire whose quiver was fuller than his purse: with one of his daughters Edgeworth eloped to Scotland (1763). The young couple spent a twelvemonth at Edgeworthstown, and finally settled at Hare Hatch, near Reading, Edgeworth meanwhile keeping terms in the Temple, till his father's death (1769) allowed him to give up all thought of the bar. As a boy of seven he had become 'irrecoverably a mechanic' through the sight of an electrical machine; and his whole life long he was always inventing something—a semaphore, a velocipede, a pedometer, and so forth. One of his inventions brought him across Dr Darwin; and at Lichfield, the Christmas-tide of 1770, he conceived a passion for lovely Honora Sneyd. His wife was away in Berkshire ('she was not of a cheerful temper'); but Thomas Day (q.v.) was with him, and urged him to fight. So with Day and his eldest boy, whom he was educating on Rousseau's system, he did fly to France, and at Lyons diverted himself and the course of the Rhone. Then his wife died, and four months afterwards he wedded Honora (July 1773), to lose her in 1780, and the same year marry her sister Elizabeth. She too died of consumption (1797); but the next wife, Miss Beaufort (1798), survived him by many years. In all he had nineteen children. 'I am not,' he observed, 'a man of prejudices. I have had four wives. The second and third were sisters, and I was in love with the second in the lifetime of the first.' Of his life besides not much more need be told. He advocated parliamentary reform and Catholic emancipation; his house was spared by the rebels (1798); and in the last Irish parliament (1798-99) he spoke for the Union, but voted against it, as a measure 'forced down the throats of the Irish, though five-sixths of the nation were against it.' He died 13th June 1817. Masterful, versatile, brilliant, enlightened, he stands as a type of the Superior Being; 'cocksureness' his principal foible. He was the idol of his own womankind, the friend too of Watt and Wedgwood and many more better and greater than himself.

MARIA EDGEWORTH, novelist, was born at Blackbourton, on New-year's Day 1767, and in 1775 was sent to a school at Derby, in 1780 to a fashionable establishment in London. As quite a child she was

famed for her story-telling powers, and at thirteen wrote a tale on Generosity. 'Excellent,' said her father, 'and extremely well written; but where's the generosity?' She accompanied him to Ireland in 1782, and thenceforth till his death the two were never separate. For his sake and that of her other dear friends and her country she sacrificed her one romance—refused the Swedish count, M. Edelcrantz, not without much suffering then and long afterwards. This was in 1802 at Paris, where, as again in 1820, and during frequent visits to London, she was greatly honoured. She was at Bowood (Lord Lansdowne's) in 1818, and at Abbotsford in 1823, Scott two years later returning the visit at Edgeworthstown. For the rest, her home life was busy and beneficent, if uneventful. Her eyesight often troubled her; but at seventy she began to learn Spanish, at eighty-two could thoroughly enjoy Macaulay's History, and even mount a ladder to take the top off the clock. She died in her step-mother's arms, 22d May 1849.

To the literary partnership between Mr and Miss Edgeworth we are directly indebted for *Practical Education* (2 vols. 1798), and the *Essay on Irish Bulls* (1802). But most of her other works, though they do not bear the joint names, were inspired by her father, and gained or (it may be) lost by his revision. Published between 1795 and 1847, they filled upwards of 20 volumes. Besides the *Tales from Fashionable Life* and *Harrington* (an apology for the Jews), there are her three Irish masterpieces, *Castle Rackrent* (1800), *The Absentee* (1812), and *Ormond* (1817). These, Scott says, 'have gone so far to make the English familiar with the character of their gay and kind-hearted neighbours of Ireland, that she may be truly said to have done more towards completing the Union than perhaps all the legislative enactments by which it has been followed up. Without being so presumptuous as to hope to emulate the rich humour, pathetic tenderness, and admirable taste which pervade the works of my accomplished friend, I felt that something might be attempted for my own country of the same kind with that which she has so fortunately achieved for Ireland.' The praise from Scott is extravagant; but Turgenev, too, has recorded how he 'was an unconscious disciple of Miss Edgeworth in setting out on his literary career. . . . It is possible, nay probable, that if Maria Edgeworth had not written about the poor Irish of County Longford and the squires and squireens, it would not have occurred to me to give a literary form to my impressions about the classes parallel to them in Russia.' Yes, her novels are too didactic; the plots may be poor, the *dramatis personæ* sometimes wooden; the whole may have too much the tone of a moral Lord Chesterfield; but for wit and pathos, for lively dialogue and simple directness, for bright vivacity and healthy realism, as a mirror, moreover, of the age when they were written, and of that 'most distressful country' in which their best scenes are laid, they still deserve to be read, by subscribers even to Mudie's. And her children's stories—'Lazy Laurence,' and 'Simple Susan,' and the other delightful old friends—are worth all the unchildish books about children which a mawkish sentimentality has brought into recent vogue.

The *Memoirs of Richard Lovell Edgeworth* (1820; 3d ed. 1844) are autobiographical up to 1782; the completion, less interesting, is by Miss Edgeworth. Of herself there is a Memoir (privately printed, 3 vols. 1867; edited by Aug. J. C. Hare, 2 vols. 1894), on which are founded the Life by Helen Zimmern ('Eminent Women' series, 1883) and the exquisite sketch by Miss Thackeray [Lady Richmond Ritchie] in her *Book of Sibyls* (1883). See, too, the monograph by the Hon. Emily Lawless (1904).

Edgings are indispensable to neatness in garden ing, except where parterres are cut out of a lawn,

but more especially to separate gravel-walks from cultivated ground. They are sometimes made of stone, or of deal, of ornamental wire and cast-iron work, and very frequently now of terra-cotta tiles in elegant patterns. Living edgings are, however, always to be preferred where they can be adopted, because they are almost invariably most pleasing and characteristic of gardening. For this purpose many low-growing evergreen shrubs are used in Britain, such as dwarf box, Cotoneaster, Pernettya, Erica, ivy, and latterly some remarkably neat and pretty dwarf Veronicas from New Zealand. Among herbaceous plants commonly used for edgings may be noted double-flowered daisies, thrift or sea-pink, gentianella, saxifrages, and many others which when in flower are highly beautiful. The only drawback in connection with these is that they require frequent, almost annual renewal. Turf-edgings are sometimes employed for wide flower-borders.

Edgware, a village of Middlesex, 11½ miles NW. of King's Cross station, stretching for about a mile along the highway. In a forge here, where he had taken refuge from the rain, Handel conceived his 'Harmonious Blacksmith.'

Edicts were issued by all the higher magistrates of Rome, especially by the Prætors (q.v.), and ultimately contributed its most valuable element to Roman Law. For the Edict of Nantes, see HUGUENOTS, NANTES

Edinburgh, capital of Scotland and county town of Midlothian or the county of Edinburgh, has since 1432 been itself a county of a city. It stands 393 miles NNW. of London by rail, and 46 E. of Glasgow (43 direct distance), in 55° 57' N. lat and 3° 11' W. long. More than most capitals, Edinburgh has concentrated in and around itself a large part of the national history, and is the pride of the country in virtue of beauty of situation, the romantic events that have taken place within its walls, the fame of its citizens in literature, science, and art, and the glamour shed on place and people by the writings of its most faithful son and citizen, Sir Walter Scott, and added to by another native, Robert Louis Stevenson. Edinburgh has been called the 'Modern Athens' in reference partly to the situation on hills near the sea and to its literary distinction in the 18th century. The town stands on a series of ridges looking down upon the Firth of Forth, and is overlooked by Arthur Seat (q.v.), and by the north-eastern end of the Pentlands (up to 1617 feet), and other hills (see EDINBURGHSIRE), now within the city boundaries. Of hills within the area of streets the highest are the Castle Rock (437 feet) and the Calton (349). Although the Castle Rock, which for centuries was considered an almost impregnable fortress, must have been a place of refuge and of arms from the earliest times, the city is not conspicuous very early in the history of this part of the country, which in Roman times was unquestionably occupied by a British or Welsh (not Gaelic) people, the Otadini, apparently a branch of the Brigantes. On the removal of the Romans it was no doubt exposed to the incursions of the Picts from the north, and may have been occupied by them. But about 617 it was conquered and held by Edwin, king of Northumbria, was doubtless fortified as an outpost against the northern raiders, took its name from the Anglian king, and for centuries formed an integral part of the great Northumbrian kingdom. It is doubtful if during the Danish troubles in the 10th century Edinburgh was taken possession of by the Scoto-Pictish kings; it did not formally become part of the northern kingdom till after the battle of Carham in 1018, when the Northumbrian kingdom had been destroyed by the Danes and Cnut was king in the south.

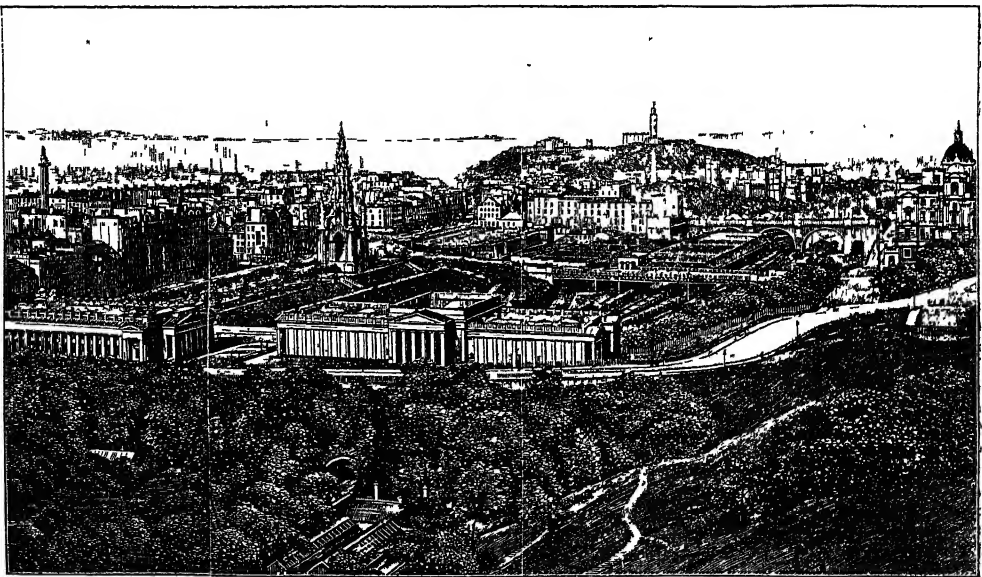

Lothian was ceded by the Northumbrian earls to the king of Alba, but remained then and since Anglian in speech and population. The Gaelic name Dun-Edin is merely a Gaelic translation of Edwinesburg or Edwinesburgh, the name we find in the charters of David I. (1128-47) and the history of Symeon of Dunblane. The old British name seems to have been Dyn Mynedd or Mynydd Agned; the late tradition that the castle was called *Castrum Puellarum*, and was a place of safety for Pictish princesses, is a fable. Christianity is believed to have been introduced, as into other parts of Lothian, in the reign of Oswald (634-642); the first church of the oldest Edinburgh parish is said to have been built about the end of the 7th century on the site where St Cuthbert's Church now stands. In the end of the 11th century, its castle figures in the story of St Margaret, queen of Malcolm Canmore, and the little Norman chapel on the summit of the rock, dedicated to her memory, is the oldest building connected with the city. Excavations below it have disclosed remains of earlier buildings. In 1128 David I. founded the abbey of Holyrood, about a mile east of the castle, on the site of a much earlier church, whose foundations have been discovered, and round it grew up the little burgh of the Canongate, which maintained its separate municipality until 1856, when it was incorporated with Edinburgh.

To the east of the castle, where the ground slopes down from the rock in a narrow 'hog's-back' (see the article CRAG AND TAIL, and the cut there), grew up the town of Edinburgh. In 1329 it was made a burgh by Robert the Bruce, by a charter which also granted the town the right of establishing a port at Leith, 2 miles distant. Thus began the vassalage of the port to the capital town, which continued until 1833, when Leith was by Act of Parliament made a burgh, thereafter enjoying independence till it was annexed in 1920 (see LEITH). It was, however, during the 15th century, under the Stewart dynasty, that Edinburgh began to be recognised as the capital, and parliament regularly met here; at first within the great hall of the castle, and afterwards in the City Tolbooth, until in 1631 the Parliament House, which still stands, was erected. James IV. and James V. confirmed its choice as the capital by building a palace within the abbey of Holyrood; and by establishing in it, in 1532, the Court of Session (q.v.) as a supreme court of justice for Scotland. In 1450 the first wall was built; and in 1513, after the defeat at Flodden, an extended wall was erected to include the suburb of the Cowgate, which had meantime arisen in the valley to the south. For two centuries and a half the town remained stationary in size, consisting of two long streets, the High Street (which was continued without the walls by the Canongate) and the Cowgate; while from these branched off numerous narrow lanes, called 'wynds,' which were also lined with houses. The town was defended on the west by the castle; on the north by a morass, called the 'Nor' Loch; and on the east and south by the city wall. As the population increased, the houses rose higher and higher, being built of the splendid freestone of the surrounding country, until the town abounded in great 'lands' of houses, which, being erected on the steep sides of the 'hog's back,' had entrances from two levels, and rose to ten, twelve, and even fourteen stories in height. This is the historic city; and it entered on the most remarkable period of its history with the birth of Queen Mary. In 1544 it was burned to the ground by the English under Hertford, scarcely a building outside the castle, save St Giles' Kirk, escaping. In 1560 the drama of the Reformation began in Edinburgh, and John Knox became the city minister; in 1561 Queen

Mary returned a widow from France, and there was acted, chiefly in Edinburgh, the staking tragedy of her short reign, which has given subject-matter to historian, poet, dramatist, and novelist. It was at Holyrood Palace that Rizzio was murdered, and in the castle James VI. was born; in the Kirk-of-Field, where the university now stands, Darnley was killed, and in the Chapel Royal of Holyrood Mary was married to Bothwell. In 1582-83 the university was founded, and the town which George Buchanan had already made known to the learned began its academic life. In 1603 James VI. left Scotland to ascend the English throne, and although parliament still continued to meet in it, the town was shorn of much of its importance. In literature the successors of William Dunbar and Gavin Douglas died out. Edinburgh was the scene of many of the fiercest episodes in the long ecclesiastical struggle of the 17th century; and its Cross witnessed the execu-

tion of Montrose in 1650, and of Argyll and his brother Covenanters after the Restoration.

The Union of 1707, which emptied the Parliament House of its legislators, and drew away the Scottish nobility from their Edinburgh mansions, was very unpopular, and the citizens long remained discontented. The Porteous mob, which Scott has made famous in the *Hew of Midothian*, showed the spirit abroad, and many of the townsmen welcomed the Pretender, and rejoiced for a brief season in the glories of the court which he held at Holyrood Palace, in 1745. But the Rebellion was followed by the inroads of modern enterprise. Shortly after the middle of the century the Town Wall was broken down in every direction, until but little now is left, save one of the towers built into the west boundary wall of Heriot's Hospital; the Nor' Loch was drained; and when the North Bridge was erected, in 1763, access was given to the northern slopes, on which arose the New Town

Edinburgh in the later 19th Century.

(a new iron North Bridge was built in 1895-96). In 1785 the valley to the south, in which lies the Cowgate, was bridged, and the town spread southwards. In 1815-19 another bridge was thrown over a deep hollow on the north-east, and the Calton Hill was connected with the city; while a few years later a bridge was built across the Cowgate parallel to the one already erected. Thus the city connected the country on north and south with the narrow ridge topped by the castle, on which she had stood for centuries. Meanwhile a greater intellectual revolution had awakened the deadness of the early 18th century. There spread northwards the wave of scientific research which rose in England in Charles II.'s reign, and resulted in the establishment of the Scottish school of medicine, of which Alexander Monro was the founder. In this important movement the town assisted materially by the foundation, in 1738, of the Edinburgh Royal Infirmary, the joint work of Monro and Lord Provost Drummond. Closely following the scientific came the mainly literary revival which has made the town known over the world. In the 18th century lived Allan Ramsay and Robert Fergusson, the fore-runners of Robert Burns, and then followed

Robertson the historian, David Hume and Adam Smith, James Hutton, Professors Dugald Stewart and John Playfair, Sir Henry Raeburn, and many lesser celebrities, such as Henry Mackenzie and Tytler, Lord Hailes and Hugh Blair. But her greatest literary period was reached when Walter Scott was writing his novels, and when the *Edinburgh Review* was started by Jeffrey, Sydney Smith, Brougham, and Horner, and *Blackwood's Magazine* by the brilliant coterie led by John Gibson Lockhart and John Wilson (Christopher North). Carlyle and De Quincey carry the succession to Stevenson.

The old historic houses of the Old Town have been largely cleared away. The New Town is regularly laid out; it contains many handsome streets and squares, ornamented with gardens; and its houses are mostly lofty and built of fine freestone. The suburbs, especially the southern, contain a great extent of villa-houses, and much rural country is included within the boundary, so that the town covers a wide space for its population—has, in fact, a greater area than Glasgow. It is also especially fortunate in its open spaces and public parks. Princes Street Gardens occupy the site of the old Nor' Loch, at the foot of the Castle Rock; the range of the Meadows and Links—the remains

of the once extensive Burgh Muir—divides the town proper from the southern suburbs; the old royal hunting-ground attached to Holyrood—the King's Park and Arthur's Seat—is open to the citizens; while on the north is the Botanic Gardens, with the Arboretum; on the south Blackford Hill and the Braids have been added to the town property devoted to recreation; and on the west the Zoological Society of Scotland has its park on the wooded Corstorphine Hill. The view obtained from the top of either Arthur's Seat or Blackford Hill is very noble and extensive; that from the latter is finely described in *Marmion*.

Edinburgh is still in some measure the capital of Scotland: it is the seat of the Supreme Courts and of some of the departments of government; in it are held the General Assemblies of the Scottish churches; and the military headquarters for Scotland are also stationed in it. It contains the head-offices of the principal Scottish banks; of some of the largest of the Scottish insurance companies, which are among the greatest institutions of their kind; and of many other financial companies trading in Scotland and even more largely in the colonies. It is the centre of much of the intellectual life of Scotland, being the home of the Royal Society of Edinburgh, of the Royal Scottish Academy of Fine Arts, of the Scottish Society of Antiquaries, and of many other literary and scientific societies. Its leisured class, which is a large one, is partly composed of Scottish landed proprietors, but much more extensively recruited from those who have returned from abroad after acquiring affluence; while the tone of its society is in great measure given by the legal bodies which practise before its Supreme Courts, and by the staff connected with the university. At the head of its legal bodies is the Faculty of Advocates or barristers, which has always included many of the most distinguished Scottish writers and politicians; then come the Society of Writers to the Signet, and the Solicitors before the Supreme Court. There are also important societies of Accountants and Actuaries. Since the middle of the 18th century it has been celebrated for its physicians and surgeons, many of whom have been known for strong character as well as scientific knowledge. These and other circumstances tend to make Edinburgh very much a place of residence, with a large well-to-do population.

It has been long known for its educational institutions, and these draw many inhabitants to the city for the benefits they offer. At the head of these is, of course, the university, and there are besides various colleges for instruction in medicine, theology, art, teaching, veterinary science, agriculture, &c., and a City Observatory. The High School and the Academy, and many of its private schools, have also attained a high reputation; but the most noteworthy feature perhaps is the exceptionally large sum which is annually derived for educational purposes from bequests left by citizens. These endowments were largely diverted for secondary education in the last third of the 19th century. Among the principal are the trust founded by George Heriot in Charles I.'s time, whose income is applied by the Act of 1885 to the maintenance of the Heriot-Watt Technical College and of George Heriot's School; the trusts under the charge of the Merchant Company of Edinburgh, applied principally to middle-class education; and the Fettes endowment, applied to higher-class education on the English model. In Libraries (q.v.) Edinburgh is rich, having besides the University Library, the magnificent national collection of over 700,000 volumes taken over in 1925 from the Faculty of Advocates, and the valuable library of the Society of Writers to the Signet, amounting to about 100,000 volumes; a free public library was erected in 1887—

89, the building being a gift of Mr Andrew Carnegie of Pittsburg. The city is known for its many religious, charitable, and philanthropic societies and institutions. Perhaps the greatest of these is the Royal Infirmary, 'open to the sick and hurt of all countries.' It has received great sums from gifts and legacies, and may almost be said to be the *ultimus heres* of all connected with the city who die without immediate heirs. It is a necessary adjunct to the great medical school, and is considered one of the most admirably appointed hospitals in Europe.

The city ranks as a county in itself, and is under the management of a corporation of seventy-one members, who elect from their number a Lord Provost and ten magistrates, called bailies. The Lord Provost, who serves for three years, takes the title of 'Right Honourable,' is Lord lieutenant of the city and Admiral of the Firth of Forth, and nominates deputy-lieutenants and justices for the city.

Edinburgh, as a residential town, is probably the most important shopkeeping centre out of London; it is not in any great measure a manufacturing town, its most important industries being brewing and publishing. It has been known for its printers since the early years of the 16th century, when Walter Chepman, under the patronage of James IV., set up the first Scottish printing-press. The publishing of books, with the subsidiary businesses of printing, lithography, bookbinding, and type-founding, is now a most important industry; and much printing is done for London houses. It is a centre for the paper-trade, as there are many important paper-mills in the immediate neighbourhood. See BOOK-TRADE. There are also very important distilleries, and large india-rubber manufactories, biscuit, chemical, and glue works, and extensive nurseries for trees and shrubs.

Edinburgh has many buildings famous in history, or important from their architectural merit. The Palace and Abbey of Holyrood (q.v.) are a memorial of the old Scottish monarchy. The castle comprises David's Tower, the old Parliament Hall, restored (1889-92) by the late Mr William Nelson, publisher, and the Queen Mary portion containing the Scottish regalia. The garrison was withdrawn in 1923 to make way for a war memorial. St Giles' Church, the old parish church of Edinburgh, dating most of it from the 15th century, was restored by Dr William Chambers (q.v.), the work being completed in 1883. The Parliament House, erected in 1633 for the Scottish parliament, is now used as the 'Outer House' of the Supreme Courts, and adorned with many fine portraits and statues belonging to the Faculty of Advocates. 'John Knox's House' was perhaps occupied by the great Reformer whilst minister of the town. George Heriot's Hospital (or School) is a beautiful 17th-century building. Many of the modern buildings are fine. The Episcopal Cathedral of St Mary's, opened in 1879, is one of the largest churches built in Britain since the Reformation. Buildings in the Greek style are numerous, and include the National Gallery, the Royal Scottish Academy, and the National Monument, all by W. H. Playfair. The Usher Hall (1911-13) is the gift of Mr Andrew Usher (d. 1898). The Medical Schools and the Infirmary occupy a noble range; while many of the museums, banks, insurance-offices, clubs, hotels, and public schools are fine buildings. Among many monuments stand out the Gothic cross in memory of Sir Walter Scott. The water-supply, first brought from Comiston in 1674, was wholly derived from the northern slope of the Pentlands, till in 1905 a copious source at Talla in Peeblesshire was made available. The municipal slaughter-houses were removed to Slateford (then without the city) soon after. Pop.

(1831) 136,548; (1881) 236,002; (1911) 320,318; (1921) 420,264. Edinburgh is divided, for municipal purposes, into twenty-three wards, Portobello (q.v.) having been incorporated in 1896, Granton in 1900, and Leith in 1920, when Cramond, Corstorphine, Colinton, Liberton, Gilmerton, and other villages, with much rural country, were also added, bringing Edinburgh's area from 10,877 to 32,401 acres. The parliamentary burgh, including since 1918 Musselburgh and Portobello, has five divisions, with five members. Leith remains a parliamentary burgh with one member; and the districts added in 1920 remain part of the parliamentary county of Midlothian and Peebles (northern division). The university combines with the other Scottish universities to elect three members.

See Histories by Maitland (1753) and Arnot (1779); Sir D. Wilson's *Memoirs* (1847; new ed. 1892) and *Reminiscences* (1878); Chambers's *Traditions* (1825, 1912); Drummond's *Old Edinburgh* (1879); R. L. Stevenson's *Edinburgh: Picturesque Notes* (1878); Grant's *Old and New Edinburgh* (1880-82); Lees' *St Giles* (1889); Mrs Oliphant's *Royal Edinburgh* (1890); Harrison's *Edinburgh Houses* (new ed. 1898); Geddie's *Romantic Edinburgh* (new ed. 1911); Bone's *Edinburgh Revisited* (1911); and the many volumes of the Old Edinburgh Club.

THE UNIVERSITY OF EDINBURGH, the youngest of the Scottish universities, is in a very special manner the child of the Reformation. In 1561 the town council moved in the matter, and ere long obtained from Queen Mary a grant of the ruins of the Kirk-of-Field, an old collegiate church. Civil war retarded the project, but in 1582 the town council obtained a charter from King James authorising it to establish a college; it was at the same time empowered to recover a sum of 6000 merks Scots, which had been left as far back as 1558 by Robert Reid, Bishop of Orkney, for the purpose of founding a college in Edinburgh. The college was opened in 1583 in very humble buildings and on a very small scale, its staff consisting of one regent, Robert Rollock, a young scholar brought from the college of St Andrews, with one assistant. In 1587 the staff was increased, Rollock becoming principal and professor of Divinity, with four regents, who each taught all the subjects of the curriculum, and conducted students through their four years' course. Such the college continued, without much material change, until the beginning of the 18th century; it was principally a school for training the Scottish Presbyterian clergy, although many of the Scottish nobility also attended its classes. In 1708, however, under the enlightened guidance of the principal, William Carstairs, the regents became professors, teaching but one subject, and a possibility was opened up for a great extension of the scope of the college. In 1724 a beginning was made of a medical faculty, when Alexander Monro became professor of Anatomy; other chairs in the same faculty rapidly followed, and with such teachers as Monro, Cullen, and Gregory, the fame of the school soon rose. The reputation of the university was extended when, towards the close of the 18th century, Dr Robertson became principal, and Dugald Stewart and John Playfair drew students in crowds. Before the end of the 19th century the number of students had reached 3500, and declined to about 3000; in 1912 there were again 3500; in 1923 about 4400, 1600 each in arts and medicine. There are some 15,000 members of the General Council.

The great influx of students during Principal Robertson's time rendered an increase of college accommodation absolutely necessary, the growth of numbers having been met up to this time by buildings erected from time to time by the town council from city funds, or by the generosity of private donors. In 1789 the foundation of the present

university buildings on the South Bridge was laid. The French war led to a withdrawal of government grants and consequent delay. Robert Adam's plans were modified by W. H. Playfair, who in 1828 completed the building but for the dome, added in 1887 by Sir R. Rowand Anderson. Augmented numbers, especially of the medical classes, called for a further increase of buildings, and a separate medical school was built in 1878-88, with a Physiological Laboratory (1901). In 1887-1906 a students' union was built; and in 1888-97 a college hall was erected at the expense of Mr M'Ewan, M.P. for one of the divisions of the city. Other university buildings are the Reid Music School (1858) and the John Usher Public Health Institute (1902). In 1906-7 the old High School (later a fever hospital) and the old Surgical Hospital were converted into Engineering and Natural Philosophy Departments. The Agriculture, Forestry, and Entomology Departments are in George Square, the Department of Mathematics in Chambers Street. A site for scientific departments has been acquired near Liberton, and chemical and other laboratories and lecture-rooms have been erected from 1919.

From its foundation in 1583 down to 1858 the university was entirely controlled by the town council, which in its early days was much guided in its choice of teachers by the city clergy. It was felt, however, that it had outgrown its original constitution, and after a Royal Commission had reported, the Universities (Scotland) Act, 1858, made the university of Edinburgh a corporation 'consisting of chancellor, rector, principal, professors, registered graduates and alumni, and matriculated students.' Its government was vested in a *Senatus Academicus*, subject to the review of a University Court representing the university authorities and the town council of Edinburgh. The powers of the court have since been increased. The patronage of chairs was in some cases vested in the crown; so far as it remained with the town council, it was transferred to seven curators, four appointed by the town council and three by the University Court. The Lord Rector is elected by undergraduates. A Students' Representative Council was founded in 1884 as a means of expressing the opinion of the body of students on university matters. Since 1918 the General Councils (chancellors, professors, members of the University Courts, and graduates) of Edinburgh and the other Scottish universities conjointly elect three members of parliament.

Among the alumni of the university are numbered Drummond of Hawthornden, Samuel Rutherford, Hume, Blair, Akenside, Goldsmith, James Thomson, John Home, Boswell, Thomson of Duddingston, James Bruce, John Leyden, David Mallet, Mungo Park, Lord Dundonald, Hutton the geologist, Walter Scott, Brougham, Cockburn, Lord Palmerston, Earl Russell, Carlyle, Darwin, Sir Richard Owen, Balfour Stewart, Clerk Maxwell, Cooke the electrician, Robertson of Brighton, J. F. McLennan, Joseph Thomson, Barrie, Crockett, R. L. Stevenson, and Sir James Dewar; while of its famous principals and professors may be mentioned Leighton, Carstairs, Robertson, MacLaurin, Dugald Stewart, Adam Ferguson, Hugh Blair, Thomas Brown, Joseph Black, Robison, Leslie, J. D. Forbes and Edward Forbes, Charles Bell, John Playfair, Sir William Hamilton, John Wilson, J. F. Ferrier, Thomas Chalmers, the Monros, David and James Gregory, Cullen, Christison, Syme, Simpson, Lord Playfair, Goodsir, W. E. Aytoun, Brewster, Lister, Masson, the Geikies, P. G. Tait, Sir W. Turner, D. F. Tovey.

The university comprises the Faculties of Arts, Science, Divinity, Law, Medicine, and Music. The university recognises as qualifying for its degrees the lectures of a large body of distinguished

extra-mural lecturers; distinct degrees are granted by the Royal Colleges of Physicians (q.v.) and Surgeons (q.v.).

Libraries, Museum, Societies.—The University Library originated in a bequest of books made in 1580 by Clement Little to the town and church of Edinburgh. This little library, consisting of about 300 volumes, was transferred by the town-council to the college on its opening. It has gradually increased. From 1709 it enjoyed the right of receiving every book entered in Stationers' Hall, but a composition of £575 per annum in lieu of the privilege was accepted in 1837. The University Library contains about 300,000 printed volumes, and 8000 volumes of MSS. The university also contains subsidiary libraries, such as the Theological Library, the Humanity Class Library, &c. The Natural History Museum was established in 1812, and received a government grant of £200 per annum. It was in 1854 transferred to the new Museum of Science and Art, now the Royal Scottish Museum, where it forms a Natural History Department. The Anatomical Museum, now exhibited in a fine hall in the new Medical School, was founded by the town council and the Senatus Academicus in 1826. The Botanical Museum is stationed in the Botanic Garden, which is in connection with the university, as is the Royal Observatory on Blackford Hill. The numerous societies for literary or scientific discussion play an important part in the training of the students. The Speculative Society was founded in 1764, and the Royal Medical in 1737. The Dialectic, Scots Law, Diagnostic, Philomathic, and Celtic constitute the Associated Societies of the university. Apart from the Carnegie Trust, the university has some 100 bursaries, about 80 scholarships, and several fellowships.

There are histories by Bower (1817–30), Dalzel (1862), Sir A. Grant (1884), and John Harrison (1886).

Edinburgh Review, the great Whig 'buff and blue' quarterly, was started in October 1802 by a knot of young men living in the northern capital, the principal of whom were Jeffrey, Sydney Smith, Horner, and Brougham. So much was secrecy felt or believed to be necessary to the success of the undertaking, that, according to the account which Lord Jeffrey gave to Mr Robert Chambers in 1846, 'the dark divans' of the reviewers were held for some time 'in a dingy room of Willison's printing-office in Craig's Close,' to which each repaired alone, and 'by back approaches or different lanes.' Of the first number, 750 copies were printed: the demand exceeded this limited supply; 750 more were thrown off, and successive editions followed. In 1808 the circulation had risen to about 9000, and it is believed to have reached its maximum—from which it has declined—in 1813, when 12,000 or 13,000 copies were printed. The pay of contributors was at first ten guineas a sheet, but shortly after 'the minimum,' says Jeffrey, 'was raised to sixteen guineas, at which it remained during my reign. Two-thirds of the articles were, however, paid much higher, averaging, I should think, from twenty to twenty-five guineas a sheet on the whole number.' The original publisher was the well-known Constable. To Sydney Smith, editor of the first three numbers, succeeded Jeffrey (1803–29), Macvey Napier (1829–47), Empson (1847–52), Cornwall Lewis (1852–55), Henry Reeve (1855–95), Arthur Elliot (1895–1912), and Harold Cox. The influence of the *Edinburgh Review* in developing and strengthening the political convictions of the Whig party cannot be overestimated; but its power was even more visible, certainly more immediately palpable, in literature. Amid the feeble and effete periodicals of the day it burst like a bombshell. The keenness of criticism, the sharpness of wit, the brilliancy of style, the vigour of mind and compre-

hensiveness of knowledge exhibited by the writers excited amazement and fear in the world of letters; and although, in the case of Wordsworth, Southey, and other writers of a certain school, unfairness of a flagrant kind was undoubtedly exhibited and persevered in, yet impartial justice was, on the whole, administered. Since Jeffrey's day the most brilliant contributor was Lord Macaulay. The *Edinburgh Review* is now published in London. See *Correspondence of Macvey Napier* (1879).

Edinburghshire, or MIDLOTHIAN, a Scottish county, extending 12 miles along the low southern shore of the Firth of Forth. The greatest length from east to west is 36 miles; its greatest breadth, 24; and its area, 367 sq. m. The surface has a general southward rise to the Pentlands, culminating in Scald Law (1898 feet), and the Moorfoot Hills, whose highest point is Blackhope Scar (2136). Intermediate eminences are Arthur's Seat (822), Blackford Hill (500), Corstorphine Hill (520), Craiglockhart (550), the Braid Hills (698), and the Dalmahoy Crags (800). The streams—Esk, Water of Leith, and Almond—all flow to the Forth, with the exception of Gala Water, which runs to the Tweed. The geology is most interesting, the rocks of the Moorfoots being Lower Silurian; of the Pentlands, Upper Silurian and Lower Old Red Sandstone, the latter consisting chiefly of volcanic rocks; and of the plains, Carboniferous, with contemporaneous and subsequent or intrusive igneous rocks. Coal has been largely mined for three centuries; and ironstone, oil-shale, and fireclay are also raised. There are large quarries of sandstone at Craigleith (q.v.) and elsewhere. Agriculture is highly advanced, though only 57 per cent. of the entire area is in cultivation. Near Edinburgh are large market-gardens; and on the Esk and the Water of Leith there are paper-mills. The county, with Peeblesshire, returns two members to parliament, and contains the burghs of Edinburgh and Musselburgh, besides the police-burghs of Dalkeith, Bonnyrigg, Lasswade, Loanhead, and Penicuik. Pop. (1801) 122,597; (1841) 225,454; (1881) 339,164; (1911) 507,666; (1921) 506,378. Midlothian's four battlefields are Roslin, Pinkie, Carberry Hill, and Rullion Green; its antiquities include the Catstane, the Roman remains of Inveresk and Cramond, Roslin Chapel, and the castles of Bothwick (q.v.), Crichton, Craigmillar, &c. It is rich, too, in fine and interesting mansions, described in Small's *Castles and Mansions of the Lothians* (2 vols. 1883).

Edison, THOMAS ALVA, a notable American inventor, was born at Milan, Ohio, 11th February 1847, but his early years were spent at Port Huron, Michigan. His father was of Dutch, and his mother of Scottish descent; the latter, having been a teacher, gave him what schooling he received. Edison was a great reader in his youth, and at the age of twelve he became a newsboy on the Grand Trunk Line running into Detroit, and began to experiment in chemistry. Gaining the exclusive right of selling newspapers on this line, and purchasing some old type, with the aid of four assistants he printed and issued the *Grand Trunk Herald*, the first newspaper printed in a railway train. A station-master, in gratitude for his having saved his child from the front of an advancing train, taught him telegraphy, in which he had previously been greatly interested; and thenceforward he concentrated the energies of a very versatile mind chiefly upon electrical studies. He invented an automatic repeater, by means of which messages could be sent from one wire to another without the intervention of the operator. He developed his system of duplex telegraphy while a telegraph operator in Boston, but it was not entirely successful until 1872. In 1871 he became superin-

tendent of the New York Gold and Stock Company, and here invented the printing-telegraph for gold and stock quotations, for the manufacture of which he established a workshop at Newark, N.J. He removed to Menlo Park, N.J., in 1876, to West Orange, N.J., in 1887. His inventive faculties getting full play, he took out over fifty patents in connection with improvements in telegraphy, including the quadruplex and sextuplex systems; the carbon telephone transmitter; the megaphone, for magnifying sound. Thence also emanated his Phonograph (q.v.), a form of telephone, and various practical adaptations of the electric light. His kinoscope (1894), a development of the Zoetrope (q.v.), led in turn to the Kinetograph (q.v.). His plant for the magnetic reduction of lean iron ores, successful as an invention, was a commercial failure. He then turned his attention to Portland cement, the casting of houses in moulds, and a storage battery, and later to various kinds of chemical plant. The number of his patents runs into thousands. He is a Commander of the Legion of Honour. See *Lives* by W. K. L. Dickson (1894) and by Dyer and Martin (1910), and the articles PHONOGRAPH, TELEPHONE.

Edmonton, now an urban district of Middlesex, 10½ miles NNE. of Liverpool Street Station. Lamb spent his last years here; here, too, is the 'Bell,' where John Gilpin did not dine. Pop. 67,000.

Edmonton, capital of the Canadian province of Alberta, stands on both sides of the Saskatchewan, and is on the Canadian National Railway and the Canadian Pacific, 793 miles NW. of Winnipeg, and 945 E. of Prince Rupert. Its population grew from 4000 to 58,821 (1921). It has, besides handsome parliament buildings and the university of Alberta, numerous churches, banks, and schools. The city owns its electric light and power, street railway, telephones, waterworks, incinerator, sewerage, and gas-system. There are 20 coal-mines in the neighbourhood, and the town is the centre of the fur-trade and of a vast area of magnificent agricultural land. See ALBERTA.

Edmund, king of the English from 940 to 946, conquered Mercia and the five towns of the Danish confederacy in 941 or 944, and also Cumbria, which he entrusted to Malcolm of Scotland, on condition that he should be 'his fellow-worker by sea and land.' He was slain by an outlaw.

Edmund, for his bravery surnamed IRONSIDE, king of the English for seven months of 1016, was a son of Ethelred the Unready, and a half-brother of Edward the Confessor. He was chosen king by the Londoners on his father's death (1016), while Cnut was chosen king at Southampton by the Witan generally. Edmund hastily levied an army in the western shires, twice defeated Cnut, raised the siege of London, crossed the Thames, and again twice routed the Danes. But at Ashington (q.v.), after a desperate battle that raged all day, he was utterly defeated, and an arrangement was entered into by which England was divided between the two kings, Cnut obtaining possession of Mercia and Northumbria, while all the south and the headship fell to the share of Edmund. It was also agreed that on the death of either the survivor was to succeed him. A few weeks after this agreement Edmund died, November 30, 1016—by foul play, many thought.

Edmund, ST, the last king of the East Angles, was born about 841, and reigned from 855 to 870. Of Continental Saxon birth, it is said he was adopted by Offa, king of the East Angles, as his heir. Scarcely anything is recorded of his reign until the Danish invasion of 866-870. After his men had been defeated by the Danes, he was slain

because he refused to abjure his faith. Thirty-three years after, his remains were translated from Hoxne to Bury St Edmunds. See *Life* by Thompson (1891).

Edmund, ST (EDMUND RICH), Archbishop of Canterbury, was born at Abingdon about 1175, studied and taught at Oxford and Paris, acquired fame as a preacher, was commissioned by the pope to preach the sixth crusade throughout England, and in 1233 was appointed Archbishop of Canterbury. He attached himself closely to the national party, and though personally gentle and self-denying, even threatened Henry III. with excommunication if he did not dismiss his foreign favourites. But Henry managed to nullify Edmund's authority by a resident papal legate; and the archbishop retired in 1240 to France, where he died in the same year. See *Life* by Wallace (1893).

Edmunds, GEORGE FRANKLIN, senator, born at Richmond, Vermont, in 1828, sat in the state legislature in 1854-59, in the state senate in 1861-62, and in 1866-91 in the United States senate, of which he was president *pro tempore* after Mr. Ailthum became president of the United States. He took part in the prosecution of President Johnson, and was author of the 'Edmunds Act' (1882) for the suppression of polygamy in Utah.

Edom (Heb., 'red') is given in Genesis as the surname of Esau, who, after leaving his father's house, went with his family to 'Mount Seir,' which he took from its earlier inhabitants, the togloolyte Horites. The name Seir or Edom was applied to the whole country extending from the Dead Sea southwards to the Gulf of Akaba, and bounded on the NE. by Moab. The mountains of Edom are steep, bare masses of chalk and porphyry, but to the east stretched a plateau favourable to vine-growing and tillage. On this side of the country lay the chief town, Petra or Sela, on the eastern slope of Mount Hor, and also Maon (Maan), Bozrah (Buseirah), and the seaports Elath and Ezion-geber on the Gulf of Akaba. The Edomites, recognised by the Israelites as near of kin, had attained to settled life and independence before them. The Edomites were conquered by Saul and subdued by David, and were repeatedly subject to Judah. After the fall of the kingdom of Judah they became masters of southern Palestine, but were defeated by Judas Maccabeus, and subdued by John Hyrcanus about 126. From about 300 B.C. the eastern part of Edom, with the capital Sela (Petra), had been in the hands of the Nabateans. After 120 the western part (Idumæa) was held by Jewish governors, one of whom, Antipater, an Idumæan, through Cæsar's favour, became procurator of all Judæa; his son was Herod the Great (q.v.). See PETRA.

See Palmer, *The Desert of the Exodus* (1871); De Luyne, *Voyage d'Exploration à la Mer Morte* (1874); Libbey and Hoskins, *The Jordan Valley and Petra* (1905); Forder, *Petra, Perea, Phœnicia* (1923).

Edriophthalmata, a section of higher Crustacea (q.v.), including the simpler and more primitive forms, in which the eyes are sessile, not stalked.

Edrisi, or IDRISI, Arab geographer, born at Ceuta in 1100, of a family that had governed Malaga, traced his pedigree up to Fatima, the daughter of Mohammed. He travelled in Spain, Barbary, and Asia Minor, and settled at the court of the enlightened king of Sicily, Roger II., for whom he made a silver map of the world and a celestial sphere. Roger invited him to write a description of the earth founded upon direct observation, sending travellers on journeys of exploration for the purpose. The *Description of the World*, or 'Book of Roger,' was not completed till 1154. Unequal in its execution, and better for Western than for Eastern lands, it nevertheless stands in the very first rank of medieval geographies. An abstract of

it was first edited in Arabic, very inaccurately, at Rome in 1592; the parts on Africa and Spain were culled in 1796-1818, and some parts (by Dozy and others) since 1866. The French translation of the whole (1836-40) by Jaubert is not very satisfactory. Edrisi wrote also on medicine and morals, and made verses. He died about 1165.

Education. The three essential elements included under the concept of education may be expressed in the following statements: (1) it deals with an organism; (2) it is deliberate and systematic; (3) it uses an organon or instrument—knowledge. Most of the definitions of education contain the word *development*. Now development implies an organism, for only an organism can develop. The first datum of education, then, is that the person to be educated—whom, for the sake of convenience, we shall call the *educand*—is an organism, and accordingly must develop after the laws of his own nature. It would almost appear, therefore, as if the educator were balked at the very threshold. If the educand must develop according to the laws of his own nature, what is the use of an educator? The usual answer is given in the form of a metaphor. The educand is compared to a plant, and it is pointed out that while the acorn cannot develop into any other tree than an oak, it may be turned into either a sound and well-developed oak, or into a stunted and decrepit one. Seeds must develop according to the laws of their own nature, and there is still room for the gardener. The educand is born into the world a bundle of potentialities which demand certain conditions before they can realise themselves. The educator can see that these conditions are presented, and by varying the conditions he can, within limits, determine the nature of the resulting reactions between the educand and his environment; can, in fact, modify the development of the educand. He cannot interfere with the laws of development inherent in the educand, but he can so manipulate the environment that these laws shall lead to results different from those that would follow were the conditions left unchanged. There are the two elements in the problem—the educand's original endowment, and the environment into which he is born. The educator must take the first as given; the second he can manipulate to a certain extent. This is the usual procedure of the educator: he modifies the environment in which the educand lives.

The possibility of modifying the original endowment of the educand introduces the problem of heredity. It would appear that this is a force that cannot be manipulated directly by the educator. The more he knows of the laws of heredity, and the greater knowledge he can acquire of the hereditary endowments of the educand, the better; but the present state of scientific opinion on this subject is strongly against the view that the educator can manipulate heredity in dealing with the educand here and now before him. The balance of evidence is certainly strongly against the transmission of characteristics acquired during the life of the individual; so education cannot hope to have the cumulative power that it might have claimed had the decision of the biologists been otherwise. Sir E. Ray Lankester tells us that 'educability can be transmitted—it is a congenital character; but the *results* of education cannot be transmitted.' Still, he adds the comforting words: 'To the educable animal the less there is of specialised mechanism transmitted by heredity the better. The loss of instinct is what permits and necessitates the education of the receptive brain.' In fact, the educator finds compensation in discovering that it is now generally recognised that many of the traits that were formerly supposed to be transmitted by

what may be called bodily heredity are really transmitted by what it is becoming usual to call social heredity. The power that was supposed to reside in heredity is now transferred to the environment. We act like our fathers not because we have inherited from them, but because we live with them and under the same conditions. With regard to congenital qualities, no change has taken place; the accepted view is that characteristics acquired during the life of the individual are passed on not by bodily heredity but by social. What is taken from the educator with the one hand is restored to him with the other, since he is able to a considerable extent to manipulate the environment.

In the state of nature the development of plants and animals is determined by external conditions, so that Nature herself may be regarded as an educator. There is a substratum of truth in Mark Twain's whimsical view that a cauliflower is only a cabbage with a college education. But here we come to our second essential in the connotation of education. It must be deliberate; in other words, there must be a clear intention to educate. Mere evolution is not education. We do not educate the tadpole into the frog, nor do we speak of Nature as educating a particular piece of elevated land into a watershed. In a wide sense, the term education may be made to include all the processes and all the influences of social life, in so far as these modify human development; but in this case we assume a purpose behind nature and society. The human race may be said to have been undergoing education from the palæolithic period, and even from an earlier stage. But in using the term in this sense we imply that Nature herself is the educator, or represents the educational purpose of some cosmic power. So with the ordinary education that results from the mere process of living in society, the licking into shape that comes from ordinary experience. We do not usually call this education, because there is no deliberate intention in the process. When the millionaire's son in Kipling's *Captains Courageous* was carried off by accident for a long experience of the hardships of deep-sea fishing, he was certainly educated; but the process could hardly be correctly called education, since neither millionaire nor fishermen had any educational purpose. The term might be rightly applied had the millionaire deliberately contrived to send his son away into this wholesome environment. In this case the millionaire would have been the educator, the son the educand, and the fishermen merely the means of carrying out the educator's purpose. In point of fact, education is always a bipolar process, the educator being at the active pole and the educand at the passive. From this it is not to be inferred that the educand is to be intrinsically passive. Indeed, one of the chief functions of the educator is to stimulate the activity of the educand. Still, so far as the process is regarded as educational, the educator always stands at the active pole. It is true that in the educative process between a given educator and educand there may be, and usually is, a gradual interchange of activity between the two poles. In so far as the educand merely reacts to the educator's stimuli in such a way as to be educated, he is educand and nothing more. But in so far as the educand comes to take a share in the educative process, to see what the educator is aiming at and to help deliberately to secure that aim, he becomes to that extent his own educator, and thus reduces the educational activity of the external educator. The really successful educator is he who by thus leading the educand to take up the work renders himself unnecessary. It is clear that even in self-education the process does not cease to be bipolar. When the educand takes himself in hand and be-

comes his own educator, using teachers and others as means towards his ends, he has still within himself the two aspects: from one point of view he is still educand, though the educator happens to be himself. The process remains bipolar.

The third essential element in the connotation of education is the use of knowledge as an instrument. That we use knowledge for this purpose has been long recognised, for the work of the school is very generally regarded as the communication of knowledge. The teacher has been, and is, generally accepted without question as an educator. This is strikingly illustrated by the fact that for so long we have been content to use one term *pupil* as the correlate of the two distinct terms *teacher* and *educator*. It is only now, when we are beginning to analyse educational processes with some degree of care, that the need for an accurate correlate to *educator* has driven us to adopt the term *educand*. But in the development of educational theory the view of the function of knowledge has materially changed. Originally the communication of knowledge was regarded as the supplying of the educand with information that was essential to him. He had to know certain things in order that he might conduct himself wisely in the environment in which he found himself. This is what is implied in the somewhat esoteric definition of education as the process by which the educand absorbs and is absorbed by the environment. As a result of this process the educand adapts himself to his surroundings, which lends some justification to those writers who regard education as a means of adjustment to varying conditions. By-and-by, however, knowledge began to be valued for its own sake, apart from any use to which it could be applied, and this disinterested view has much to recommend it. But it gradually led to a curious misunderstanding of the relation between knowledge and power. Obviously knowledge of our environment is power. But when studies had become greatly elaborated, their subject-matter ceased to have any connection with the practical affairs of life, and therefore the studies lost their *prima facie* claim to rank as power-givers. Naturally, the school people who spent their lives in acquiring and communicating this abstruse knowledge did not see their way to admit the practical worthlessness of their acquirements. They therefore hit upon the theory that subjects have to be studied, not for the intrinsic value of the knowledge they supply, but for the training effect on the mind. Certain subjects are to be studied for the intrinsic value of the subject-matter, and certain others for the training to be obtained in the process. This view is usually known as the doctrine of 'formal training.' It has had its day, but is now generally discredited. Herbert Spencer used the law of parsimony as an argument against it, maintaining that it is contrary to the laws of nature that we should have to learn one set of subjects for the sake of acquiring knowledge, and another for the sake of training the mind. This is hardly convincing; but the careful investigations of such writers as E. L. Thorndike have made it clear that while there is a certain amount of transference of power from one subject to another, the amount of this transference is in direct proportion to the number of elements that are common to both subjects. It cannot be denied that the careful study of any subject will to some extent train the mind, but it is no longer a tenable position that certain subjects should be chosen for the sake of training alone, quite irrespective of the value of the subject-matter. The old faculty psychology gave some support to the 'formal-training' theory; but with the recognition of the essential unity of all mental process, it has

become clear that it is not reasonable to set apart special studies in order to cultivate special faculties of the mind. On the other hand, it is admitted that there are certain general ways of regarding things that may be transferred from one kind of mental activity to another. Professor W. C. Bagley, for example, maintains that certain ideals of such things as neatness, accuracy, perseverance, may be acquired in dealing with one subject, and yet be applied to others. In this attenuated form the doctrine is generally accepted.

What gave a certain strength to the 'formal-training' doctrine was the unreasonable faith many people showed in the power of mere knowledge. Facts were regarded as of value merely as facts. 'If cramming means the acquiring of facts, then cram, cram,' said a distinguished teacher, with a full knowledge of the opprobrium attached to cram. Opposed to this view was that of 'drawing out,' largely based upon etymological grounds. Considerable confusion sometimes prevails in educational writing with regard to this drawing-out process. Sometimes it is rightly confined to the drawing out of latent powers, but not infrequently it is applied to the elicitation of knowledge. It is forgotten that we cannot draw out what is not there. The mind must be nurtured as well as exercised.

Education may be regarded from many points of view. It may be considered in connection with various categories. With regard to the incidence of the personality of the educator, we have *direct* or *indirect* education. When the personality is exercised without the intervention of books, or studies, or the manipulation of environment, we have obviously the direct form. When we have education classed as *material* and *formal*, we are dealing under the category of the value of knowledge as intrinsic and as means of training. The distinction between *positive* and *negative* education is based really on Rousseau's view that we must not interfere with the course of nature. We must learn how wisely to lose time. He regards as positive education all those forms that seek to modify the development of the educand at the will of the educator, apart from considerations of the natural development of the human being. The Froebelianists, with their definition of education as 'a passivity, a following,' are clearly exponents of negative education. One is apt to think of Comte in connection with the positive form, but the Comtist view of education is represented by the term *integral*. It is difficult to suggest an inoffensive correlate to *integral*. The obvious term *fractional* represents an ideal that no one would be willing to accept. Perhaps *sectional* is the least irritating term. Integral education does not mean that everybody should be taught everything, though this is the only meaning that M. Jules Simon can take out of the term; but that the body of knowledge presented to the educand should be thoroughly organised. Instead of being a thing of shreds and patches, it is to be worked up into a whole, in which each part is organically related to all the others. The ideal is excellent, but the Comtists have gone but a little way towards its realisation. *Specific* and *general* are the two terms that result from the consideration of education under the category of the use to be made of it. In some cases the purpose of education is to produce a certain type of man. Thus seminarist education is specific. On the other hand, education may have as its aim the production of a mere all-round man—one who is prepared in a general way in all directions, without any bias for any particular walk in life. The non-professional parts of education at the universities illustrate the general form. A very interesting category under which education may be considered is that of the agent by whom it is

conducted. Huxley speaks of 'artificial' education, meaning the education that is given deliberately by men as opposed to that given by nature. All education would thus be either natural or artificial. But as the term *natural* is often used in educational writings to indicate artificial education when carried on in accordance with the laws of nature, there is a certain danger of confusion; so it is sometimes suggested that the terms *human* and *cosmic* should be substituted, the second term covering all cases of education carried on by nature, the world-spirit, God, apart from any deliberate share in the work by human beings. Lessing's curious little book on *The Education of the Human Race* is a treatise on cosmic education in this sense.

We must distinguish between education and educational theory. Even in the form of human education, in the sense defined above, there must have been education long before there was any theorising about it. Letourneau devotes a whole chapter to *Education in the Animal Kingdom*, in which abundant evidence is given of more or less purposive training of the young. This stage corresponds to cosmic education, and the same is true of the earlier stages of the education of man. It is only when men begin to take themselves in hand, when they deliberately set about making themselves different from what they are, that true human education may be said to begin. In the course of evolution man gradually becomes aware of the nature of the process, and begins to take a hand in helping it forward. So soon as he begins to intervene in the evolutionary process he becomes an educator, and introduces the elements of educational theory. For long the theory is very crude, and consists mainly in speculations regarding the most satisfactory mode of producing the best sort of man to fulfil certain necessary functions in society. All education begins as specific education.

This preparation for specific work introduces a permanent struggle between the educational ideals of the individual and of society. No doubt when viewed from the point of view of eternity the two ideals coincide, but at the short range of ordinary life it is sometimes hard to reconcile them. Mr Benjamin Kidd assures us that the interests of society and of the individual are inherently opposed to one another; so we need not be surprised to find that there is trouble in meeting the demands of the individual and the state with regard to education. In the old Greek states, where the theory of education practically began, so far, at any rate, as concerns written records, we find the claims of the state predominant. In Sparta the individual was entirely subordinated to the state; and though in Athens there was greater scope for the individual, he was always made to feel that in the ultimate resort he belonged body and soul to the city. Of the thinkers of that time Socrates was more individualistic in theory than Plato; but Socrates recognises the supremacy of the state, since he consented to die in obedience to the laws, even while recognising their injustice. Plato regards the state as supreme, and goes the length of holding that the happiness of the whole may be gained at the expense of the parts. Here Aristotle vigorously opposes him, and practically sets up the organic ideal in which the parts and the whole can reach full development only when both have free-play. In his famous paradox, 'The state is prior to the individual,' he emphasises the interdependence of the individual and the state. But though man is so constituted that he cannot be himself except in a state, it does not follow that he exists for the sake of the state. The truth is that the state exists for him. If man be regarded by the statesman as a mere means to attain public ends, then

the state can never get the best out of the individual. Though in the *Republic* the citizen is throughout subordinated to the state, from the lowest grade to the highest, yet in the Athens of Plato's time the free citizens certainly regarded themselves as ends and not as mere means. The wise educator must take full account of the need to recognise every educand as an end, though it may be necessary also to keep in view his function as a means. In the Aristotelian system the educator has to take his orders from the statesman, since education is a practical science that produces materials to be used by another science. Politics is architectonic to education. In modern states it cannot be denied that this is the principle on which education is conducted. In sober truth, the educator is subordinated to the statesman. But this does not by any means imply that the determination of the aim of education is to be settled by another science. In so far as the statesman interferes with the aim or method of education he ceases to be a statesman, and to that extent becomes an educator.

In the ultimate resort true education and true statesmanship cannot but agree that the final aim of all education is the self-realisation of the individual. Many other aims have been put forward—to prepare for complete living; to secure a sound mind in a healthy body; to produce perfect citizens; to develop children as imperfect human beings into perfect human beings; to secure the harmonious development of all the faculties; to secure the adjustment of the individual to his environment. Yet each and all of these may be fairly claimed as a part of self-realisation. There is, indeed, only one of the recognised views of the aim of education that cannot be said to be included under the wider term, and this is the Herbartian view that the aim of education is the cultivation of many-sided interest. It will be shown that this aim is necessary in order to give content to the other.

Self-realisation recognises the independence of the individual, and at the same time does not deny the need for a social environment. The individual is educated not so much by the state as in the state. We must get rid of the idea that in a healthy state there can be any antagonism between the self-realisation of the citizen and the best development of the state. Confusion sometimes arises, because it is assumed that self-realisation means the removal of all external restraint. This error is implicit in the term that is sometimes used as if it were an equivalent—*self-expression*. Both self-realisation and self-expression imply the existence of a self; but the first regards the self as a potentiality to be developed; the second, as something ready-made, and only seeking a mode of expressing itself. Those who are pertinaciously claiming the right to 'lead their own life' are really working on the self-expression ideal. Self-realisation does not necessarily imply freedom from restraint. Often restraint is of the essence of the process that aids in the development of the true self, and should be welcomed by the educand who understands his own ideals.

It is for metaphysicians and psychologists to discuss the possibility and nature of a self; the educator is entitled to assume its existence and to busy himself about its development. Here arises one of the difficulties of self-realisation as the educational ideal. There is the implication that all selves are either neutral or are inherently good. If we are merely to aid the educand in realising the potentialities of his self, we must help the bad self to become a perfectly bad self, just as we help the good self to become a perfectly good self. Self-realisation must therefore be limited by the proviso that it is confined to the development

of the higher or better self that is possible to each educand. This implies that the educator has to take a stronger line in education than at first sight appears. He must not only aid the self of the educand in its development, but must select those elements in it that are worthy of encouragement, and do all he can to suppress the others. It is here that the need for the supplementary ideal of many-sided interest becomes manifest. Self-realisation is a somewhat empty ideal. 'Realise thyself' is not a helpful exhortation by itself. It needs to be supported by a reference to the environment in which the realisation is to be carried out. The presentation of content in an ordered way is an essential part of the work of the educator. The communication of knowledge and the manipulation of the environment are integral parts of the educator's function. The knowledge communicated is valuable for its own sake and also as a means of training; but the ideal on which Herbart laid stress was the effect upon the self of the subject-matter dealt with. The result is a sensitiveness to certain cognitive and affective impressions: the self has acquired a permanent interest in certain worthy elements that have been selected by the educator. Interest which in the educative process has been a *means* becomes as an educational ideal the *end*. Self-realisation remains the final goal of education, but many-sided interest supplies the wider ideal with the content necessary to make it effective.

History of Education.—As in prehistoric and early historical times all knowledge was in the hands of the priests, it is natural to suppose that the beginnings of education would be in their hands too. At first education would be confined to the priestly class themselves, and to those young people who were marked out by their birth for high estate. It would certainly be to the advantage of the priestly class to acquire influence thus early with those who were to be the leaders of the tribe or nation. With regard to the common people, the only education they required was the education of life. They learnt by the mere process of living. Imitation and convention were the forces that moulded them into the shape required by the society in which they lived. Education would be purely specific—the learning of a trade or occupation of some sort, with the ordinary social customs that went with the corresponding social grade. In the ordinary histories of education we usually find at the beginning some vague generalities on the state of education among the early Chinese, Egyptians, Indians, and Persians. But we really know remarkably little about education among those early peoples. It is probable that in the case of China that 'cake of custom' of which Walter Bagehot speaks proved too strong to allow of the freedom necessary for further development, and that education was one of the instruments used in the hardening process. The education rapidly became literary, and has remained so throughout the ages. In India, and especially in Egypt, the history of education is really inferred from the progress of the nation in actual knowledge. While the Egyptians were learning astronomy and geometry, as testified by the evolution of the pyramid into a time-measurer, they must have passed on from generation to generation the knowledge as it was acquired. There must therefore have been practical education, and it is unlikely that among such intelligent people there should be no theory of education at all. It has to be remembered that the priests owed their power to their skill in manipulating the warrior-class; so it is exceedingly likely that they studied human nature with great care, and it is only natural to suppose that the experienced priests would communicate their knowledge of human nature to

their successors, and this would amount to a theory of education since it included a system of manipulating knowledge in order to produce certain definite effects upon individual human beings. With regard to Persia we have a few vague notes, gathered together by Xenophon and slung out into his *Cyropaedea*. The schools of justice sufficiently indicate the general ideal of the education attempted, and the saying that among the Persians the young were taught to ride, to tell the truth, and to use the bow indicates that there was already a discrimination between moral and physical training. It is not till we come to Greece, however, that we have a full record of both theory and practice of education. In Sparta and those states that followed this type, the education was specific both for slaves and for citizens. Each of the slaves had to learn his particular trade; while the citizens were all trained to the same trade—that of soldiering. In states of the Athenian type the education of the citizens was still to a certain extent specific, since every man had to be able to bear arms and to take his share in the government of the state. But there was greater freedom of individual action. All had to learn gymnastics for the body and music for the soul. But into the term 'music' much or little could be read. In Sparta it was confined to the uses that could be made of it in warfare and the things connected with warfare. In Athens it was made to include poetry and literature, and even a certain amount of science. Education was public in both types, began at the age of seven, and was continued to eighteen; though the period from eighteen to thirty might not unfailingly have been also called a period of educational probation. In Athens the Sophists arose to meet the demand for individual instruction. They were regarded with great disfavour by the more conservative statesmen, as tending to sap the old authority of the state. Aristophanes and Xenophon had no sympathy with them, and did all they could to favour a return to the simplicity of the olden times. It is because he had this thesis to maintain that we regard Xenophon's *Cyropaedea* with a certain amount of suspicion as a record of what actually was the state of affairs in Persian education. In Plato's *Republic* and in Aristotle's *Ethics* and *Politics* we have the first recorded systematic statements of educational theory. In both cases we have the current state of Greek education taken as the basis of the theory; though in the case of Plato we have this used with great freedom as the mere material for an imaginative reconstruction, whereas in the case of Aristotle we have the experience of the past used as a guide in the logical development of a general theory.

Among the Romans education was essentially specific. The citizen was trained to fulfil his duties as citizen whether in peace or in war. While the great nobles had private tutors for their sons, the ordinary citizens sent their boys to schools that bore very clearly the impress of Greek influence. On the theoretical side, Roman education is best represented in Quintilian's *Institutes of Oratory*, in which an account is given of the education of an orator. By profession Quintilian was a trainer of orators. But among the Romans an orator was not a mere maker of speeches. He was a man of affairs, both civil and warlike. Before a man could hope to be an orator he had to become an all-round well-trained man. Accordingly the education of an orator resolved itself into general training and special. Quintilian considered the educand in all his relations and not merely as an orator, though no doubt oratory was the goal of the specific education up to which the general led. Thus it is that his *Institutes* is regarded as one of the classics of education. With the introduction of Christianity

a different view was naturally adopted. Instead of seeking to train men who would be useful to the state and capable of governing other men, it turned to the spiritual development of the individual. Men were still to be trained as citizens, but of a city not made with hands. The beginnings of Christian education are to be found in the catechumenal schools, where neophytes were instructed in the doctrines of the faith before admission to membership of the Church. These schools, at first very informal, gradually developed into definite institutions, and are commonly known as catechetical schools, from the question-and-answer form of the instruction. The natural development followed. As Christian dogma became more firmly established and more logically elaborated it demanded more and more intellectual skill to understand it. Accordingly, there was a differentiation between the mere lay pupil and the pupil who had capacity and inclination for deeper study. An intellectual atmosphere was cultivated, and those who aspired to office in the Church had to give evidence of power to deal with the new body of doctrine. Gradually the schools became the repositories of whatever learning was available at the time. As the Roman empire decayed, the distinction between the pagan schools and the Christian would become more marked, and the increasing organisation of the Church would give the Christian schools an advantage. Gradually schools became attached to all the great churches and cathedrals, and the concentration of whatever learning there was into church connections became more and more marked. Parallel with this bookish learning went on the practical education of life. There was an education of the castle as well as of the cloister. The soldier, the artisan, and the merchant found education for themselves. The boy of common birth but warlike connections received instruction in arms in the castle courtyard; as page and as squire, the well-born was prepared for the duties of knighthood; the apprentice was trained to his craft, and the son of the merchant to business.

The further development of the bookish side of Christian education led to the establishment of the universities, which were to a considerable extent free institutions so far as teaching went, though the influence of the Church is manifest in the limitations within which the schoolmen did their ingenious thinking. It was after five centuries of this over-elaborate refinement of thinking that the reaction came in the form of the Renaissance. The rediscovery of the classical literatures must be regarded as merely one of the important elements of a great movement that signified the bursting of the fetters of human thought. It is at this stage that the 'isms' of education begin—the first, very naturally, being *humanism*. As a philosophy of life it resolves itself into the claim for free development of the individual; each is to be entitled to develop the humanity that is within him. The joy of living is to be recognised, and artificial restraints are to be removed. In its essence humanism is not necessarily a bookish movement. In fact, part of its creed is a protest against the limitations of books, and a plea for more life and fuller. In education, however, the humanistic movement naturally depended upon books to bring back the ideas of the old classical times which, seen through the haze of centuries, seemed to offer a freer and happier medium of life-realisation than could be found in the present. But while the early humanists made an extensive use of books, it was for the sake of the matter they contained. Their aim was not the study of languages as such, but the use of language in order to get at the thoughts of the writers of the classical times. It was not till humanism had lost

its early enthusiasm, and had hardened into a complicated system of education, that the claim was put forward that the mere classical languages as such were the best educational instrument. Scholarship in the narrower sense of that word did not form an essential part of the original humanistic ideal. The Renaissance schools began in the true spirit of humanism. Vittorino da Feltre's (1378–1446) school at Mantua realised the older humanistic ideals, and justified them by the very name it adopted—'The pleasant house.' The same cannot be said for John Sturm (1507–89), whose *gymnasium* at Strasburg exemplified the mechanical degeneration of the humanistic ideal. With him education was mere linguistic. The school course was divided up into the work of the ten classes. Each pupil had to fit into the Ptolemaean limits of each class, for it was as great an offence to be in front of the work of the class as to be behind it. Yet, such as it was, Sturm's *gymnasium* has proved the type on which the German system of secondary education has been modelled. It is sometimes said that our own English public schools are the lineal descendants of the Strasburg institution; but while there may be an element of historical truth in the assertion, it must be borne in mind that our English schools have developed another side on which they justly pride themselves. While the Continental schools surpass ours in regard to instruction, ours claim precedence in so far as education is involved. Old Sturm would certainly not acknowledge the present English public school as approaching his ideal.

What is called realism in education is usually regarded as a reaction from humanism. Its usual cry is, 'Things, not words.' It is easy to show that it is possible to over-emphasise things quite as much as words. The truth naturally is that we must not—in fact, cannot—separate things and words. The real motto ought to be, 'Things and words in their proper relations.' Nothing else is of any value. Realism is, therefore, a protest against verbalism, rather than against humanism. As a matter of fact, the humanists are as keen about the realities of life as are the professed realists. It is only a degenerate humanism that lays itself open to attack on the grounds of verbalism. John Amos Comenius (1592–1670), for example, is usually classed as a realist, yet most of his text-books are little more than collections of words. It is true that he makes a special point of correlating, as far as possible, words and ideas. His *Orbis Pictus*, for instance, consists of a series of words and phrases directly connected with a set of pictures, the more complicated of which have careful reference-marks. It may be just as truly said that he approaches things through words as that he approaches words through things. The truth is that there is the greatest difficulty in classifying educational theorists as humanists and realists. We have humanistic-realists like Erasmus, sense-realists like Mulcaster and Bacon, social-realists like Montaigne. In modern times, however, there is a more definite meaning attached to the terms humanism and realism. The subject-matter of a school course determines whether it is humanistic or realistic. Matters dealing directly with human interests, and, in particular, languages and the fine arts, are marked off as humanistic; while the natural and physical and mathematical sciences are set apart as the *real* of realism. The distinction is most strikingly made in the contrast between the German *gymnasien* and *realschulen*.

Naturalism as a form of educational theory does not concern itself specially with instruction at all, whether in the form of words or of things, but rather with the process of living. Rabelais (1483–1553) is sometimes classed as a humanistic-realist,

but he may be equally well ranked with the naturalists. The most striking example of naturalism, however, is Rousseau (1712-78), who in his *Émile* (1762) gave the world a book that has probably had more influence on education than any other that has ever been published. His principle is that man is born good, but is gradually corrupted by society. Education consists, therefore, in keeping the child free from contamination till such times as his character is fully formed. Education is thus *negative*. The educand is to be allowed to develop naturally without any external influence. The only book he is to be allowed to read is *Robinson Crusoe*, and the only people he is to be allowed to have communication with are his tutor and the people of the house and village, from whom it would be impossible to isolate him without making him practically a prisoner. But the tutor is to do all the manipulation of life, and a thoroughly artificial system is the result of this naturalistic scheme. Naturalism in education is now mainly associated with reactions against an over-bookish tendency. The athletic side of our English schools represents the naturalistic movement, and several private schools in England have been established on professedly naturalistic lines.

There is a good deal of confusion in educational theory about the meaning of the term *nature* in connection with naturalism. It may mean either the nature of things or the nature of the educand. Obviously the two meanings run into each other, and it may not unreasonably be maintained that the nature of the educand must necessarily be included in the nature of things. But it is of some consequence where the incidence of the emphasis occurs. It has been claimed, for example, that Rousseau is the first writer who has adopted what Dr Stanley Hall calls the paidocentric point of view—that is, the view that regards the whole problem of education from the standpoint of the nature of the educand. He must, however, share this honour with John Locke (1632-1704), who in his *Thoughts on Education*, an unsystematic but very practical treatment of the educational problem, gave us the first book that makes the child the centre of the problem. The Jesuits, too, in their educational system made a very definite application of the paidocentric view. The idealist writers on education, who were powerfully influenced by Rousseau, are very much inclined to adopt the policy of following nature without analysing too closely the connotation of the term. Pestalozzi (1746-1827) and Froebel (1783-1852) both base their theories on a more or less clear appreciation of the idealist philosophy prevalent in their time. There is no doubt that if Froebel had been questioned whether he proposed to follow the nature of the child, or nature in the sense of the nature of things, he would have replied that it did not matter, as it would be impossible to follow the one without following the other. Pestalozzi's influence was that of a prophet rather than a philosopher. He knew little about psychology, and produced his remarkable results by the sheer force of personality and native insight. Froebel was much more systematic—too systematic, some of his critics maintain. His kindergarten system is built up on a metaphor. The school is regarded as a garden and the children as the plants. The teacher has the office of gardener. The plant-metaphor is excellent so far as it goes; but it necessarily breaks down, because children, in plain English, are not plants, but something much higher. The introduction of the idea of self-consciousness must modify the whole position. However, as a stage in the development of true educational theory, Froebel's work was of the first importance, and the later developments of his system are on the whole satisfactory.

The Froebelian position tends to become too negative. 'A passivity, a following,' comes to be a rather depressing ideal; so the more positive doctrine of Johann Friedrich Herbart (1776-1841) was very generally welcomed. Founding on an atomistic psychology that cannot be defended, he erected a system of educational theory in which the value of nurture is emphasised as opposed to the paralysing view that everything depends upon original endowment. It is hardly too much to say that Herbart regarded as possible a process that would be named by the older philosophers 'an implanting of faculty' in the educand. The Froebelians and the Herbartians each over-emphasise one aspect of the truth. Between the two comes Dr Maria Montessori, who gives the Froebelian self-activity a practical turn, and applies to the education of normal children the lessons she learnt in using the motor methods that have proved so successful in training defectives.

The materialists, as represented by La Mettrie (1709-51), D'Holbach (1723-89), Helvétius (1715-1771), and Huxley (1825-95), treat the human being as a machine, and in this way simplify a great many of the problems of education for those who can accept their premises. Herbert Spencer (1820-1903) represents the evolutionary-utilitarian point of view, and his little book on *Education*, in spite of the criticisms to which it has been subjected by educational experts (or perhaps because of these criticisms), has probably exercised more influence than any other book on education published in English during the 19th century. At the present moment educational theory has become more consolidated than it has ever been before. There is now a large body of views that are generally accepted, however much opinions may differ in other particulars. The most promising line of advance at present appears to be in the quantitative analysis of educational problems, and in the experimental work associated with such names as Meumann, Dewey, Claparède, and Nunn. The correlation formulæ of Pearson and Spearman hold out great hopes. Expert psychologists are at present collaborating with experienced students of education all over the world, and there is every prospect of valuable results.

ENGLAND.—By the Education Statute of 1406 the English parliament had proclaimed the right of every man and woman 'to set their son or daughter to take learning at any school that pleaseth them within the realm.' Then in 1410 the Court of Common Pleas decided that by the common law of England any one had a right to teach. There was thus in England freedom of learning and freedom of teaching. The law did not recognise the right of the Church to monopolise the licensing of teachers. Yet, as a matter of fact, it was for centuries practically impossible to teach in schools without a license from some church official. The history of national education in England, from the 14th century onwards, is largely a record of the struggles between different religious parties for the control of the schools. It has been shown by recent investigations that in the last quarter of the 14th century there was a much more complete system of primary, secondary, and university education than had been generally supposed. Through the struggles with Lollardy the system as a system was broken down, though the effect of the Lollard spirit on the education actually given was good. The increased use of the vernacular and the greater freedom of thought were gains for education. A similar movement marked the great Reformation, of which the Lollard movement was the precursor. There was an advance in the national ideal of education, but this was accompanied by an actual set-back to the national system. The new learning

was just what was needed to revive the somewhat barren teaching of the pre-Reformation schools; but, unfortunately, a great many of these schools were killed off by a misuse of the legislation of 1547. Henry VIII., and still more Edward VI., used to get the credit of founding a great many new schools. But Mr A. F. Leach seems to have proved in his *English Schools at the Reformation* that in the times of these monarchs many more schools were suppressed than founded, and that many of their foundations are, in reality, merely readjustments of foundations that were already in existence. Leach tells us that in 1535 there were in England about 300 grammar-schools, and that most of them were swept away through the plundering of the ministers of Henry VIII. and Edward VI. It is likely that this is somewhat exaggerated, and that many of these schools had been already ruined by the storm and stress that accompanied the breakdown of medieval learning before 1535. In any case, there appears to have been a sufficiently large number of schools suppressed by Henry and his son to justify Leach in describing them as spoilers of schools rather than as founders. In 1563 the Speaker of the House of Commons made a striking statement of the lack of schools, and yet in 1581 Richard Mulcaster gave the assurance that there was no cause of complaint regarding the number of schools. In point of fact, the Elizabethan period includes no fewer than 148 new foundations, and 34 additional foundations. James I. followed a liberal policy in education, but the troubles of the succeeding reign stopped progress; and though Cromwell inaugurated a progressive policy, it was cut short at the Restoration, and the various restrictions culminating in the Act of Uniformity of 1662 brought the grammar-schools to low-water mark. It has been said, with some truth, that from 1662 to 1870 the grammar-schools of the country were totally inefficient. At this point we come to a very peculiar phenomenon. Of the 8000 endowed schools now existing in England and Wales, no fewer than 1100 were founded between 1660 and 1730. The fecundity of these seventy years is traced to the result of *Bate's case*, in which it was decided that a schoolmaster presented by the founder of the school or by a lay patron could not be ejected because he had not a bishop's license. This was a direct encouragement to dissenting founders, and to those churchmen who wished the Church to keep to her proper sphere. During the 18th century higher education in England was practically dormant, but the period was marked by a quickening of the public conscience with regard to the education of the poorer classes. This became more marked towards the end of the century, and resulted in the payment of the education of the poor at the expense of the parish, and in an extended founding of charity schools.

Real popular education was greatly favoured by two movements, that marked the passage from the 18th century to the 19th. The first of these is the establishment of the Sunday-school, which in its beginnings was not merely a religious institution, and was not confined to children. Secular subjects were taught (the school meetings lasted two or three hours, not merely one as at present), and sometimes evening-classes during the week were included as part of the system. The other movement was the application of the monitorial system, claimed as an invention by both Dr Bell and Joseph Lancaster; though it was developed in Paris by the Chevalier Paulet in 1790, and is found explicitly described in John Brinsley's *Ludus Literarius* in 1612. Bell belonged to the established Church, and was concerned with the foundation of the National School Society in 1811. Lancaster was a dissenter, and worked under the British and Foreign School

Society, formed in 1814 after having existed in other forms for some years previously. These two societies became the educational powers that dominated the administration of education through a great part of the 19th century. So strong had public opinion become on the education question that parliament began to take it up. There was an abortive Education Bill in 1820; in 1828 Lord Brougham made his famous 'schoolmaster-is-abroad' speech, and following on the Parliamentary Reform of 1832 came the earliest grant in aid of education. The parliament's first grant towards 'educating our masters' amounted to £20,000, and was to be spent in building schools (not including teachers' houses), half the cost having to be provided in each case from local contributions. The amount was quite insufficient; many schools for which the local contribution was forthcoming had to remain unbuilt, though the parliament made another dole of £20,000. In all cases the application for a share in the grant had to be made with the approval of one of the two great educational societies. In the allocation of the grant there was a discrimination in favour of large schools, and also a bias towards town schools. The depressing effect on rural education has been felt ever since. In 1834 a grant of £10,000 was made for founding model schools for the purpose of training teachers, but was not expended till 1839, when it was handed over to the two societies. In that year a Committee of Council was appointed to superintend the spending of parliamentary grants for education, and accentuated that violent religious, or, rather, ecclesiastical, dispute about the control of education, that has lasted to the present day. From 1850 to 1870 there was an uphill battle fought by those who wished to see a state system of education established. In 1856 the Education Department was founded under the control of the Vice-president of the Committee of Council, who could sit in the House of Commons. Along with the Education Department was the Science and Art Department. This had originated in the parliament's desire to further technical education by the foundation of the Government School of Design in 1837. In 1853 parliament made its first grant to the Science and Art Department. In 1856 this department was removed from the control of the Board of Trade, and worked as a more or less independent organisation alongside of the Education Department. It was not till 1899-1900 that the two departments were officially made one, under the name of the Board of Education.

The final struggle to establish compulsory education began in 1859, and resulted in success in 1870; though it should be noted that the Education Act of that year does not make education compulsory, but only gives the right to local authorities to make it compulsory if they please. During this period of struggle was introduced that system of individual examination and 'payment by results' that did so much to deaden the educational work of the elementary schools. For this system we have to thank Robert Lowe (Lord Sherbrooke), whose Revised Code of 1861-62 marks its establishment. At the beginning its influence was probably for good. It introduced a certain amount of order and method where there had been nothing but confusion, and it certainly braced up the teachers. It was when it had settled down into dead routine that it laid its chilling hand on all initiative, and imposed a mechanical ideal upon all. In 1890 it was substantially modified, but it was not till 1897 that it was completely abolished. As the Elementary Education Act of 1870 did not define elementary education, there was room for the school boards to give as advanced instruction as they thought desirable. In 1900,

however, this right was challenged, and by the Cockerton judgment it was decided that 'a school board out of money raised by rates might not provide for any instruction which was outside the curriculum prescribed by the code issued by the Education Department for elementary public schools.' This decision effectually prevented the school boards from continuing to compete with the endowed schools; but immediately afterwards the boards themselves had to make way, under the Education Act of 1902, for the education committees of the County and Borough Councils, which were authorised to control both elementary and secondary education. The London area was provided for by a special act in 1903. With the school boards went the technical education committees that under the Technical Instruction Act of 1889 were empowered to aid technical or manual instruction out of the rates. Thanks to certain customs and excise duties that were made available for educational purposes, these committees were able to do much good work, which is now being carried on with considerably less difficulty by the one educational authority that is responsible for all sorts of education in each district.

With the act of 1902 came the distinction between provided (council) schools and non-provided (the old voluntary) schools. In the words of the act, the former are 'schools provided by the local authority'; the latter are not provided by the local authority, but by some organisation (usually religious) that provides the buildings, and makes all necessary repairs other than those involved in fair wear and tear. Subject to the conscience clause, denominational religious instruction may be given in the 'non-provided' schools, but not in the 'provided' schools. The council appoints four of the six managers of its own schools, the other two being appointed by the borough council or parish council. In 'non-provided' schools four of the managers are appointed by the organisation that provides the school, and the other two are appointed by the council in whose area the school is situated. The council has the power to direct the secular instruction of a 'non-provided' school, and to inspect it. But the managers have the right to regulate the religious instruction, and to appoint and dismiss teachers, subject to the approval of the council—which, however, can intervene only on educational grounds. The Nonconformists were strongly opposed to certain of the provisions of the 1902 act, and the government that came into office in 1906 made several attempts to carry a bill that might serve as a compromise between the two parties. But the bill of 1908 was dropped at the last moment because the two parties could not agree on the contracting-out clause. These failures left the Church uneasy, the Nonconformists indignant, and the administrative authorities unsettled.

Mr Fisher practically ignored the ecclesiastical question in the Act of 1918. By this act education was made compulsory up to the age of fourteen, and all exceptions were swept away. After fourteen the pupil may either continue full-time attendance at a suitable school till he attains the age of sixteen, when he becomes quite free from further compulsion, or he may take part-time instruction at a continuation school from fourteen to eighteen, this instruction to be received in the daytime. The minimum amount of instruction is fixed at 320 hours per annum, the arrangement of these hours to be left, within reasonable limits, to the local authorities. 'Works' are allowed to have their own schools, under suitable conditions, that include government inspection. Special attention is paid to the health and social welfare of the young persons under this act. The recreative side is to be developed. Playing fields, baths, holiday camps,

and other amenities find a place in the schemes that are to carry out the terms of the act. All manner of manual arts for both boys and girls are to be introduced into the continuation schools, but the aim is to be educational rather than vocational. An important innovation is the permission to the local education authorities to provide nursery schools for children below the ordinary school age.

The 'whisky money,' as the grants under the Local Taxation (Customs and Excise) Act of 1890 were called, was continued to the councils, but with the condition that it must be spent entirely upon education 'other than elementary'; though the restriction to technical education was now removed. The power was also granted to levy a rate, which in the case of the counties must not exceed twopenny, but is unrestricted in the case of the county boroughs.

The tendency of all this educational activity since 1902 is clearly towards centralisation of power in the Board of Education, modified by a very healthy local interest in the schools. The difficulty of distinguishing between secondary and elementary education has been surmounted by defining secondary education as 'other than elementary,' where by elementary is meant what is taught in a public elementary day-school during school-hours. All evening-schools are therefore technically secondary, whatever the subjects taught. The education other than elementary includes first of all what are called the 'great' public schools. Those are, in alphabetical order, Charterhouse, Cheltenham, Eton, Harrow, Marlborough, Merchant Taylors', Rugby, St Paul's, Shrewsbury, Wellington, Westminster, Winchester. In the next group are the endowed schools of the type of the City of London School and the Manchester Grammar School. Many of these are independent of public aid, and thus stand outside the control of the Board of Education. But many of the less well endowed schools now receive state aid, and are thus subject to inspection by the Board. Then come the proprietary schools, that work under a scheme that guarantees that they are not carried on for private profit. To this class belong schools like those of the Girls' Public Day Schools Company. Another and an increasing group is made up of schools actually founded and entirely financed and controlled by the local authority. It is getting customary to call these 'municipal secondary schools.' Some of them are doing excellent work, but just at present they do not have quite the status that will certainly come to them in a few years. In some cases they are regarded as nothing but the old 'higher grade' schools under a new form. The final group of secondary day-schools is made up of what are called private schools, the official *differentia* being that they are carried on 'for private profit.' In the case of the weaker schools this profit is gradually being turned into a loss, through the competition of the state-aided schools, and none but the thoroughly efficient private establishments are likely to survive; though for these there will probably always be found a clear scope, particularly in the case of girls' schools.

The Training of Teachers.—The national system of training teachers is a development of the monitorial system, and the pupil-teacher system that arose out of it in 1846. There is some dispute as to which was the first training-college in Great Britain, which is only natural, since no institution of this kind springs into being fully formed. The plan of using schools to give teachers a training for their future work was in operation in many directions in the early part of the 19th century, and out of these experiments were evolved such institutions as David Stow's college at Glasgow and the training-college at Battersea. The building grant in 1839 was the beginning of the government sub-

sidising of the training of teachers, and this rapidly developed into a system of maintenance that practically paid all the expenses of training the students apart from the provision of premises. The ordinary course was for the pupil-teacher to serve a five years' apprenticeship—afterwards reduced to four years—and thereafter, if successful in what was called the Queen's Scholarship Examination, to pass into one of the colleges under one or other of the two great societies. There the student obtained further instruction in general subjects, and also a careful practical training in the work of teaching; passed an examination at the end of each year of training; and was then certified as a competent teacher of the second, third, or fourth class. This certificate could be raised to the first class only as the result of at least ten years' successful teaching. The pupil-teacher system has now given way to the student-teacher system, under which the intending teacher begins by a course of, at least, three years as a pupil at a secondary school, usually, but not necessarily, as a county scholar. This is followed by another year, during which the candidate remains at the secondary school as a 'bursar.' The next year may be spent either as a 'second-year bursar' at the secondary school, or as a 'student-teacher' attached to an elementary school, where he (she) has opportunities for observing good methods of teaching, and for practising a little on his (her) own account. During the student-teacher year the candidate attends at a secondary school (usually the one in which he (she) was educated), for one whole day per week, or two half-days, in order to keep up his (her) private studies. A qualifying examination must then be passed, and the candidate is admitted to a two years' course at a training-college as before, but the certificate obtained on leaving is not classed; it is merely a permission to practise as a certificated teacher. Certain of the better qualified students are allowed to combine a university course with their practical training. This course formerly covered three years, but by a regulation made in 1911 the course has been extended to four years—the first three to be spent mainly in academic work, the last year entirely in professional training. Hitherto there has not been much opportunity of training provided for teachers who intend to work in secondary schools. But there are now several separate colleges for secondary women teachers, and almost all the universities have courses of training and teaching diplomas to correspond. A Register of Teachers was established by the government in 1902, with a Registration Council to administer it. But the scheme miscarried, and by the Education (Administrative Provisions) Act of 1907 was abolished. The Regulation of the Order in Council constituting the Registration Council ceased to be operative on 31st July 1906, and the council was not reappointed. A new Teachers' Council was authorised in 1911, which, with 73,000 registered teachers, parallels the General Medical Council.

The universities of England fall naturally into two classes: Oxford and Cambridge on the one hand, and all the new universities on the other. Durham is a connecting link between the two groups. It is difficult to find a name for the new group. They resent being called 'provincial' or 'municipal.' Perhaps 'modern' or 'civic' may turn out to be an acceptable term (see UNIVERSITIES).

WALES.—With regard to elementary education, Wales has always been included in legislation that affected England. On the secondary side, following the recommendation of Lord Aberdare's Committee of the Education Department (which sat in 1881), the Welsh Intermediate Education Act was passed in 1889, and placed Wales ahead of England in secondary educational legislation till the changes

of 1902. The intermediate schools, established as a result of the act of 1889, varied greatly in the range of their curriculum. Some were little more than higher elementary schools; others were quite able to supply the Welsh university with students straight from their benches. The three university colleges—Aberystwith (1872), Bangor (1884), and Cardiff (1883)—were united to form the University of Wales in 1893. In the struggle for secondary and higher education, Wales has shown great public spirit and has made great sacrifices.

SCOTLAND.—What gave Scottish education its special characteristics was the parish school. This originated in the admirable ideal of Knox set out in the first *Book of Discipline*. His scheme implied, 'first, a school in connection with every kirk or parish, in which the ordinary branches and Latin should be taught; second, a higher school or college in cities and notable towns; and, third, university instruction for those who showed aptness for learning.' This ideal was never completely realised, but its existence did much to maintain a high standard of popular education in Scotland. In 1646 the Scottish parliament passed an 'act for founding schools in every parish,' and made regulations for the rating to produce the necessary money, the schoolmaster's stipend being fixed at not less than 100 and not more than 200 merks. This led to a rapid increase in the number of schools; but though the act provided for the appointment of 'twelve honest men within the bounds' to see that its provisions were carried into effect, there were still parishes left without a school; notably in the Highlands. In 1662 this act was repealed, and a depressing time followed. But in 1696 the provisions of the act of 1646 were revived, with such changes as experience had shown to be necessary. In these two acts we find the legal foundation of the parochial school system of Scotland. The parish schools were always practically under the control of the Church. From the Reformation to the passing of the act of 1872 the appointment of the masters of the parish schools was entirely in the hands of the Church of Scotland. Even in the schools that sprang up in the burghs the Church claimed, and in many cases obtained, the appointment of the masters; though the burgh authorities in other cases resisted, and kept the patronage in their own hands. The parish schools varied considerably in merit, but speaking generally they represented a remarkably high standard of popular education. Dr John Kerr in his *Scottish Education* is able to boast 'that all the subjects, till lately, required for the Cambridge "Little-Go" examination were at the end of the 18th century, in some districts, not seldom taught in village parish schools.' In the north-eastern counties of Scotland—Aberdeen, Banff, and Moray—the parish schools in the 19th century reached an exceptionally high state of efficiency, owing to the encouragement given by the application of the Dick and Milne Bequests, the funds of which are still available for popular education. An important element in maintaining the high standard of attainments among the parochial schoolmasters was the close connection between the school and the pulpit, schoolmasters being very often fully qualified probationers waiting for an appointment to a church. Scotsmen are particularly anxious that Englishmen should note that in the act of 1872 that introduced compulsory education into Scotland there is no mention of the phrase *elementary education*. On the contrary, there is a provision that 'the standard of education which now exists in the public schools shall not be lowered.' Further, the school boards which were brought into existence by this act were called upon to apply a compulsory clause, not to choose, as in England, whether they would

apply it or not. From 1872 to the present time education in Scotland has followed much the same lines of development as in England. In the primary schools there was always much more of the higher work done than was attempted in the corresponding English schools, and in a great many cases there was a 'secondary department' added to the elementary school. But in June 1906 there was brought about a reorganisation of the secondary education of Scotland. All schools, whatever their history and to whatever category they formerly belonged, became 'intermediate' if they provided a three-year course of secondary education, and 'secondary' if they provided a course of at least five years. The 1918 Scotch Education Act is largely a measure of devolution. The central authority passes on a great deal of power to the new education authorities appointed *ad hoc* on a county basis to take the place of the nine hundred and more school boards that are abolished. The new authorities have the control of all grades of education short of the universities, and educationists are interested to see how the *ad hoc* scheme will work out compared with the rival scheme in England. Full-time education is now compulsory up to fifteen, and continuation work is compulsory from fifteen to eighteen. The secondary schools promote the supply of teachers by giving a three-year course for 'Junior Students,' who afterwards, as 'Senior Students,' take up the training provided by the Provincial Committees at the universities—Aberdeen, Edinburgh, Glasgow, St Andrews. Students in training for secondary work must, as a rule, take university honours in the subjects they propose to teach.

IRELAND.—The religious question has rendered the progress of national education in Ireland very difficult. At the beginning of the 19th century efforts were made to establish schools in which the pupils from the two communions could study all the secular subjects in common, and receive their religious instruction apart. This was the aim of the Kildare Place Society that was founded in 1811, and began to receive government grants in 1814. Its scheme included the reading of the Scriptures, but without note or comment. To this the conscientious Catholics could not submit, and the Catholic Church was able to render the society powerless to carry out the scheme. After several educational commissions had reported, the House of Commons in 1831 made a grant of £30,000 for national elementary education in Ireland. This money was not a fresh grant, but was merely the diversion of money that was withdrawn from the Kildare Place Society and the Society for Discourteous Vice. For the administration of this public money a board of seven members was appointed, and thus was originated the Board of Commissioners of National Education in Ireland. The members were unpaid; though they soon found it necessary to have a resident commissioner with a fixed salary. The number of commissioners was gradually increased, till in 1860 it was fixed at not more than twenty, half of whom were to be Roman Catholics and half Protestants. By keeping in their own hands from the very beginning the right to inspect the schools they controlled, they avoided much of the friction that marked the development of the English educational administration. The principle of combined secular, and separate religious, teaching was maintained throughout; though at the earlier stages an excessive amount of time was devoted to the religious section—sometimes as much as two whole days a week. Local control was in the hands of a patron or patrons for each school. Committees could rank as patrons, but in the great majority of cases the patron was an

individual, and in the Catholic schools almost invariably a priest. A particular kind of schools favoured by the board was bitterly opposed by the Roman Catholics. These were the model schools, which gave a higher education than the others, but on account of the opposition they aroused were never able to do all that had been expected of them. An excellent bit of work done by the board was the preparation of textbooks; but certain economic and religious difficulties prevented this part of their work from becoming permanent. The Powis Commission of 1868 reported very elaborately in 1870, but it was not till 1883 that its recommendations were more or less carried into effect. In that year the system of voluntary denominational training-colleges was introduced into Ireland, and the course of training was increased from one year to two. In that year also it was agreed in the House of Commons, without a division, that the time had come to introduce into Ireland the principle of compulsory education. It was not till 1892 that free education was introduced for all between the ages of three and fifteen. An important element in the development of Irish education is the work of the Christian Brothers, a teaching body founded in 1802, recognised by a papal bull in 1820, having in 1825 eleven schools and forty teachers, and now, perhaps, the most influential teaching force in Ireland (see CHRISTIAN BROTHERS).

With regard to secondary education, we have the usual record of schools despoiled in the past; but the beginning of modern secondary educational administration may be said to be the establishment of the Board of Commissioners of Education in Ireland in 1813. The commissioners did their work as well as could be expected from unpaid officials, who were busy men and had little encouragement to exercise freedom of action as commissioners. Several committees and commissions reported with but small effect, till in 1885 the Educational Endowments Act was passed, which brought matters up to a point that corresponded to the English Endowed Schools Act of 1869, and still more to the Scotch Educational Endowments Act of 1882. The insuperable prejudice against co-operation in education between the Churches forced the government into the development of a system of examinations in secondary subjects that should encourage the teaching of these subjects irrespective of the school in which they were taught. The Intermediate Education (Ireland) Act was passed in 1878, and established an unpaid Board of Commissioners of Intermediate Education, whose business it was to provide an examination system on such a basis that prizes and certificates were given to deserving candidates, and a grant paid to the school in which they received their education. By the Government of Ireland Act, 1920, the capital funds of this board were divided between the governments of Southern and Northern Ireland.

Trinity College and the University of Dublin are practically identical, since there is no other college included in the university. This institution supplied the higher education for the Protestant population. Maynooth College dates from 1795, and finally became a part of the Catholic University opened in 1854. By 1882 this university had six constituent colleges. To provide for the higher education of all classes, without distinction of sect, the act of 1845 led to the foundation of three Queen's Colleges—at Belfast, at Cork, and at Galway. These were opened in 1849, and in the following year the Queen's University was formed to examine and grant degrees to the students attending these colleges. A change of name took place in 1879, when the Queen's University became the Royal University of Ireland. In 1910 a more

radical change took place, when the Royal University gave place to the National University of Ireland, which includes the University Colleges of Cork and Galway and the new University College of Dublin that was founded in 1909. The old Queen's College of Belfast ranks from 1909 as the Queen's University of Belfast.

CANADA—There is no Minister of Education for the whole Dominion of Canada, the administration of educational affairs being left entirely in the hands of the governments of the nine separate provinces. Of these, British Columbia has a Minister of Education, who is also Provincial Secretary; Prince Edward Island has a Superintendent of Education; Manitoba has a Minister of Education, who is also Municipal Commissioner. In the rapidly developing Saskatchewan it is natural that the Minister of Education should also have to look after the treasury, railways, and telephones as well; while in the old-established Ontario there is a minister who gives his whole time to education. The general principle of Canadian administration is that education shall be compulsory and free. It is always a charge on both the central and the local funds. The compulsory clause is, however, somewhat generously interpreted, particularly in the parts that are just being settled. But, speaking generally, the advantages of education are so highly prized that there is no difficulty in maintaining a reasonable attendance at schools, even under very trying circumstances as to weather and distance. Every effort is made to bring education within the reach of all. Thus in Saskatchewan the territory is divided up into areas of twenty-five square miles, for every one of which an elective board of school trustees is appointed. The schools cannot be said to be secular, as in Australia, but in five provinces out of the nine they are unsectarian, and even in the remaining four the difference consists in the provision of separate schools for Roman Catholics. In Alberta, Ontario, and Saskatchewan these separate schools are found, and in Quebec there are two Boards of Education—a Protestant one and a Catholic. But though in the east of the province the Roman Catholics greatly outnumber the Protestants, there is an arrangement by which a minority may secure a separate school wherever it can show anything like a reasonable case. In this province there are two universities—McGill at Montreal, and the Roman Catholic University of Laval at Quebec. It is with cause that Ontario is proud of its educational system, whether it be justified or not in claiming it to be the best in the world. The University of Toronto ranks with McGill among the best on the continent of America. Indeed each province has now at least one university, and there are nearly twenty degree-granting bodies within the Dominion. The teaching of agriculture gets special attention: there is at Guelph a large and well-equipped college for students of this subject. Thanks to the munificence of Sir William Macdonald, there is also an excellent agricultural college and training-school for teachers at Ste Anne, near Montreal.

AUSTRALIA AND NEW ZEALAND.—The education given in all the states of this group is very much alike. So far as elementary education is concerned there are three terms that may be generally applied to it—free, compulsory, and secular. New Zealand differs from the Australian states, inasmuch as its educational administration is not so strictly centralised. The Minister of Education has as right-hand man the Inspector-general, who controls the central Board of Education, and keeps it in touch with the schools. On the other hand, though the inspectors take their orders from the central authority and have to

see that the code is duly carried out, they report to the local authorities; though, of course, the reports finally find their way to headquarters. Elementary education is covered in six standards, the highest standard being equivalent to what is called the seventh standard in England. The elementary course is usually finished about fourteen, and thereafter provision is made for a secondary course that should cover four years, but that much more usually consists of only three, and in many cases of only two. So far as public education is concerned there is no gap between the elementary system and the secondary. From the nature of the Dominion there is a greater demand for a practical education than for a purely literary one; though, in proportion to the population, higher education is well provided for. There are over thirty endowed schools and colleges; and there are institutions of university rank at Auckland, Christchurch, Dunedin, and Wellington, which form the federal University of New Zealand, which has maintained a high standard of degree work, and has kept in close touch with the best university traditions of the old country.

The universities of the Australian Commonwealth are not of this kind, but follow the Scotch or the provincial English type. Each of the states has now a university; Sydney dates from 1850, Melbourne from 1855, Adelaide from 1874. Brisbane began work in 1910, and Perth got into working order in 1912. Even Tasmania has a little university of its own, with a rapidly increasing enrolment. The strictly secular character of the elementary instruction in Australia has had the effect of encouraging secondary private schools. The ideal towards which Australia is working is a national system of free primary, secondary, and university education; but at present the secondary system is largely in the hands of private persons and religious bodies. In New South Wales in 1916 there were 701 private schools. In Victoria secondary education is all but entirely carried on in private schools. In Queensland the 10 grammar-schools, with 6 new high schools, make a poor show as against the 154 private schools with their 19,857 pupils; and South Australia can show only 23 high schools to balance the 218 private schools. In Western Australia the private schools received a grant up to the year 1895, when it was stopped, with compensation to schools that had been already receiving it. The Commonwealth shows a very keen interest in education. In all the state governments there is a minister responsible for this part of public administration, and all the special difficulties of a sparsely populated area are effectively dealt with. Victoria and New South Wales are very proud of their educational systems, but they are keenly alive to the need of keeping abreast with modern developments. All the states take pains to keep themselves in touch with what is going on elsewhere, and their official reports give evidence of extraordinary alertness.

UNION OF SOUTH AFRICA.—The Union has a Minister of Education, who is also responsible for mines and industries; but it was provided in the South Africa Act, that 'Education other than higher education, for a period of five years, and thereafter, until parliament otherwise provides, shall be and remain under the jurisdiction of the respective Provincial Councils.' It has been provisionally agreed that higher education shall mean post-matriculation education. Accordingly the Provincial Councils have the control of elementary and secondary education, while the minister controls university and technical work, including the first-class certificate examination for teachers. Education for white children is practically compulsory throughout the Union, there being only a

small percentage of white children of school age not under instruction. Attendance is good throughout, but particularly at the characteristic private farm schools, where it reaches 95.5 per cent. The difficulty about the languages is likely to settle itself to the satisfaction of all parties except the extreme Dutch patriots. The advantages from a purely business point of view of a knowledge of English are such that parents of foresight are insisting upon their children getting this knowledge. The pressure for English instruction is coming from the Dutch themselves. The University of the Cape of Good Hope, which was incorporated in 1873, was a purely examining body, but in 1916 it was federated with several colleges as the University of South Africa. In the same year the Victoria College was turned into the University of Stellenbosch, and the South African College into the University of Cape Town.

BRITISH INDIA—The statistics of the subject are very incomplete, all that are available being found in the *Quinquennial Review of Education*, published by the government. The figures in what follows are taken from the *Review* for the quinquennium ending in 1917. The first five universities were Calcutta, Madras, Bombay, Allahabad, Punjab. To these were added in 1917 Mysore University and a Hindu University at Benares. Dacca and Patna are the next two, and Rangoon and Nagpur are to follow. There are altogether 184 affiliated colleges (156 in British territory, 25 in native states).

Secondary schools fall into four classes: English high schools, English middle schools, vernacular high schools, vernacular middle schools. The three following statements may be held to be applicable to all secondary schools: (1) Boys leave school at sixteen, or on having attained the stage of advancement that is usually reached at this age. (2) English is the medium of instruction in the two or three top classes in those schools that are classed as English. No English is taught in the vernacular schools. As a matter of fact, there is only one vernacular high school in India (Punjab). (3) The total expenditure on secondary education averages 27.6 rupees per pupil. The average direct expenditure per pupil is 5 rupees, of which the direct *public* expenditure amounts to 3.6 rupees.

The difference between high and middle schools is like that between *gymnasien* and *pro-gymnasien*. The middle school is merely a high school with two or three of the top classes cut off. The curricula of the secondary schools are largely determined by the matriculation at the universities. The teachers' qualifications and pay 'are below any standard that could be thought reasonable,' but have improved lately.

In India primary education is defined as the education of the masses through the vernacular. In some cases (Bombay) the elementary schools feed the secondary, but in general there is no connection between primary and secondary education. The number of boys at elementary schools in 1917 was 5,183,169, being 4.2 per cent. of the male population. For these there were 219,167 teachers (of whom 65,818 were trained), giving one teacher to about 24 pupils (in 1912 it was 27). Of the elementary schools, about a quarter are publicly managed. Of the privately managed schools, less than one-fifth are under missionary management. The average number of pupils in a school is 39; in 1912 it was 33. The salaries of primary teachers in board and municipal schools vary greatly—from 7.7 rupees per month to 18.6. These figures help us to realise how misleading it is to generalise about India as a whole. The government grants are extremely small, the annual amount per pupil varying according to district from 1.4 to 3.9 rupees.

The payment of fees is general throughout India, but the system is softened by liberal exemptions in necessitous cases. The fees are low, averaging 14.5 annas per annum in ordinary schools and 7½ annas per annum in government schools. As to curriculum, the three R's are taught universally; geography is almost universal; history is taught in only some of the provinces. Physical exercises are compulsory in all the provinces except Burma. The deplorable system of payment by results was recommended for general adoption in India in 1882-83, but is now found only in Burma. The figures given above for elementary education apply only to boys. The number of girls attending primary schools in 1917 was 627,908, which shows an increase over the preceding quinquennium of 164,359, and thus indicates a very rapid development. Of these girls a little less than 60 per cent. attend schools for girls only, while rather more than 40 per cent. attend mixed schools. Co-education is customary in various degrees in the elementary schools up to the age of eight. It appears that the people do not resent co-education in the way that Europeans had expected. Certain educational advantages are sometimes recognised, and the familiar administrative advantage of cheapness is generally acknowledged. In one mode or another, female students are receiving instruction in the same branches of professional and general knowledge as men—except in Oriental studies, engineering, and agriculture. There are 12 arts colleges for women, with a total of 369 students, as compared with 122 arts colleges for men. Women are admitted to men's arts colleges, but they seldom seek admission. Professor Karve's university for women at Poona is likely to extend. It is a private and unaided institution.

GERMANY.—The history of elementary national education in Germany, as elsewhere, is a history of social and ecclesiastical struggle. After the enthusiasm roused by Pestalozzi and Fichte came reaction. The name of Ferdinand Stiehl is rendered notorious because of his 'Regulative' issued in 1854 to counteract 'over-education,' and reduce to their proper level the primary schools and the training-colleges that prepared their teachers. The teachers were not permitted to learn anything beyond what they were to teach in the elementary schools. In the schools themselves the method to be adopted was the mere communication of elementary knowledge, largely by means of learning by heart. The general lowering that resulted led to reaction in its turn, and in the Bismarckian era a more progressive policy was followed. The training-college curriculum was enriched, and the regulations for the elementary schools not only widened the curriculum and demanded better methods, but inaugurated a scheme for a higher kind of elementary school to be called the *mittel-schule*. This was to take a place between the elementary and the secondary school. It was to have not less than five, but usually six, classes, where the ordinary subjects of the elementary course would be carried to a more advanced point. But this type of school has not been a success, not because of its organisation or curriculum, but because of its social bearings. Like our own higher elementary schools, it has always suggested unfavourable comparisons with the real secondary schools. It has no privileges; cannot be called a 'higher' school; secures no exemptions, military or educational. While this is true in Prussia, it is worth noting that in some German states and in Austria the term *mittel-schule* means secondary school.

In Germany as a whole, elementary education is free and compulsory between the ages of six and fourteen. It is extremely thorough so far as it goes, but it is not co-ordinated with the secondary

system. The elementary schools (*volks-schulen*) form an independent system for pupils who are expected to finish their education at fourteen. Any higher education for such pupils is to be sought in the technical and other continuation schools that are carried on mainly in the evenings. The Scandinavian type of people's high school is finding favour in Germany, and a great deal is being done for popular adult education. The highest form of secondary education implies a nine-year course, preceded by a preparatory course of three years. The classes for the nine years have a uniform nomenclature in all kinds of schools. The German *Sexta* corresponds to the English Form I, *Quinta* to Form II, *Quarta* to Form III, *Unter-Tertia* to Form IVb, *Ober-Tertia* to Form IVa, *Unter-Sekunda* to Form Vb, *Ober-Sekunda* to Form Va, *Unter-Prima* to Form VIb, *Ober-Prima* to Form VIa. The nine-class institutions fall into three great groups, differentiated from each other by the curriculum. The *gymnasium* includes in its course both Latin and Greek. The *ober-realschule* gives no Latin or Greek, and makes French the basis of the teaching of languages. It restricts its teaching, in the main, to subjects belonging to our own times. The *realgymnasium* comes midway between the other two, and compromises by leaving out Greek and retaining Latin. It otherwise favours the modern spirit, and concentrates its teaching in the upper forms on the sciences and modern languages. There has been great jealousy among the three types of schools. Originally only pupils who had followed a complete course at a *gymnasium* were eligible for admission to the university. The *gymnasium* was regarded as a universal institution—an *einheits-schule* that prepared for all branches of university study. Its pupils were trained on both the classical and the modern sides, or, in the college phrase, *sub utraque*. This utraquistic preparation, as it is called, proved to be too great a demand, leading as it did to an unreasonable increase in the age at which students could begin their university course, and to overpressure in the schools. As the result of a long struggle, in which the claims of *realien*, or exact sciences, were pitted against those of humanism, it was finally arranged in 1900 that a complete course at any one of the three types of schools should qualify for admission to the university. It is worth noting that in the controversy the newer schools claimed that the literary part of their course consisted of the 'newer humanities.' It has been suggested that there should be a fusion between the *ober-realschule* and the *realgymnasium*, and this is not unlikely to result from the development of the so-called *reformschulen*, in which no instruction is given in Latin till the fourth year (*unter-tertia*), French being started in the first year (*sexta*). Even in the *gymnasien* there are now cases in which the beginning of the classical languages is postponed—French to the fourth year (*unter-tertia*), and Greek to the sixth (*unter-sekunda*). In the German system the use of the prefix *pro* indicates that the school in question has only the first six classes of the nine-year course. Its highest class is the *unter-sekunda*. Thus a *pro-gymnasium* has no *ober-sekunda* or *prima*. This break between *unter-sekunda* and *ober-sekunda* is an important one, for it marks the limit at which the pupil may claim exemption from the longer period of military service. On promotion from *unter-sekunda* he is entitled to his *einjährig-freiwilligen-zeugnis*, which entitles him to limit his military service to one year. In proportion to its population Germany is particularly well supplied with universities of high rank. There are in fact twenty-one of them. Though supported by the state and under state control, they have

preserved in a very remarkable way *Lehrfreiheit* and *akademische freiheit*. The first leaves the professors perfectly free to teach according to their convictions, and the second secures to the students such complete freedom that many writers—notably Nietzsche—regard it as a positive danger. The student may take his course a year at a time in different universities. He usually follows distinguished professors, if he can afford it. That is, he may go one year to Leipzig because of one distinguished professor; the next to Halle because of another. In Germany the question is not so much, 'At which university have you studied?' as 'Under what professors have you studied?' The *lernfreiheit* leaves the student perfect freedom to attend whatever lectures he likes, an extension of even the American elective system. The final degree examination tests whether the student has made a wise use of the *lernfreiheit*. There is certainly nothing to complain of regarding the average German student in the matter of honest work.

Germany is particularly strong in the matter of technical schools of all kinds. The great institution at Charlottenburg is frequently held up for our imitation, and it has been more than once suggested that technical education in London should be organised on this model; though it is only fair to say that the education at Charlottenburg, though admirable, is not quite so advanced as seems to be thought in London. The following list of technical institutions from the English edition of Paulsen's *German Education* may be found useful: Technische Hochschulen (Technical High Schools), Berg-Akademien (Mining Academies), Forst-Akademien (Schools of Forestry), Landwirthschaftliche Hochschulen (Agricultural Colleges), Tierärztliche Hochschulen (Veterinary Colleges), Handels-Hochschulen (Commercial Academies), Kriegs-Akademien (Military Academies), Artillerie-Schulen (Schools of Gunnery), Ingenieur-Schulen (Schools of Engineering).

FRANCE.—The present educational system of France is based upon the Napoleonic reconstruction that culminated in 1808 in the foundation of the Imperial University, whose grand master was an educational autocrat, responsible only to the emperor. The interruption of the Restoration period was not sufficient to break down the system, since the old universities had so completely disappeared that there was no material for the new government to build a fresh system upon. It has been said that French secondary education was the most aristocratic in the world, and it is rather remarkable that the Republic has been able so to modify the imperial organisation as to satisfy democratic ideals. Napoleon's purpose was not only to educate France, but by means of education to dominate men's minds, and the Republic does not seem averse to adopt the same attitude, at least on the negative side. Every precaution is taken that the centralised system of education shall at least not act against the government ideals. Even in schools that receive no aid from the state, government inspectors have the right of entry to examine text-books, exercise-books, and note-books, so as to make sure that nothing is being taught against good morals or against the state.

Though highly centralised, French education has local as well as central control. The Minister of Education is the centre of all authority. There is a general complaint that this minister has too much to do. Everything must be directly authorised by him, and the result is that he spends a good deal of time officially approving of matters that must of necessity be really determined by subordinates. He has three councils to help him. The *Comité du Contentieux* of seventeen, mostly lawyers, advise

him in cases of disputes. The *Conseil Supérieur* is made up of fifty-seven members (partly nominated, partly elected), who are all connected in some way or other with educational work; has advisory administrative and disciplinary powers; and is guided by a committee of fifteen of its members, who do the greater part of the work, since the *conseil* itself meets only twice a year. The third council that is at the minister's disposal is the *Comité consultatif*, which has three branches—primary, secondary, and superior. This plan of supplying an official with a council is characteristic of French educational administration. Thus the *prefet* of each *département* has a certain amount of educational control, and to help him is provided a *conseil départemental*. The real educational unit, however, is not the *département*. The French educational system is really the outcome of the former system under which the University of France controlled all education—primary, secondary, and superior. In 1896 the fifteen faculties within the French Republic were made into universities, and their general organisation and their relation to schools were determined by six administrative decrees during 1897. The country is divided up into seventeen geographical areas, which are known as *académies*. Each of these areas includes several *départements*, and is named after the town or city within its boundaries that is the seat of an institution of higher learning. Every *académie*, except Chambéry, has such an institution with at least a full faculty of letters. Over each *académie* is a rector, who is the supreme authority on education of all kinds within the area of his *académie*, and is responsible only to the Minister of Education. The council set apart for the help of the rector is known as the *Conseil d'Université*, dating from the Napoleonic time, but owing its present form to the changes of 1880. The rector is appointed by the president, and must hold the doctor's degree. His right-hand man is the academy inspector, who is in many matters his vice, but whose main independent functions are with the primary education in his *académie*. Primary education is free, and compulsory from six to fourteen, but by means of *écoles maternelles* and *classes enfantines* at the beginning, and *cours complémentaires*, *écoles primaires supérieures*, and *écoles manuelles d'apprentissage*, accounts for the ages between three and sixteen. But in France there is no organic connection between the primary and the secondary system. It is not impossible to pass from the primary to the secondary, but there are very few who do. The two systems are juxtaposed rather than co-ordinated.

The French secondary schools fall into two classes—the state schools and the free schools. The latter include those schools that were formerly conducted by the religious orders, but are now transferred to private individuals or to companies. To this class also belong certain independent schools, including the ordinary private schools, some of which are based upon English models. The state schools are either *lycées* or *collèges*. The former are to be found only in the large towns, and are entirely controlled and supported by the state. The *collèges* are partly supported by the local authorities of the district in which they are found, but are practically under as strict state control as the *lycées*; though efforts are being made to encourage the local authorities to take more interest in the *collèges*, and modify them to suit local requirements. *Collèges* are to *lycées* as nearly 5 to 2, but the *lycées* educate 50 per cent. more pupils than all the *collèges* put together. Teachers in both classes of schools have the same standing under the state, for since 1889 all teachers are servants of the state, and receive salaries from the national treasury.

Both classes of state secondary schools take day-pupils, and many of them have hostels. In some 200 of the *collèges* the principal is permitted to farm the boarding arrangements under suitable restrictions, though the local authority is responsible in the last resort for any deficit that may occur.

The history of secondary education in France presents an almost exact parallel to the struggle between the *gymnasien* and the *realschulen* in Germany, and the result has been the same—diversity of type with equality of privileges. In France, however, the diversity of type has been secured in the same institutions, and has therefore greater elasticity than is to be found in the differentiated institutions in Germany. A complete secondary course in France includes ten classes. There is, first, the preparatory division, with its first-year class and its second-year class. Next comes the elementary division with the *classe de huitième* and *classe de septième*. Then follows the secondary course proper, divided into two cycles. The first cycle includes four years, and comprises the *classes de sixième, cinquième, quatrième, and troisième*. The first cycle has two parallel divisions. The A Division includes Latin from the *sixième* upwards, while Greek is voluntary from the *quatrième* upwards. In B Division there is neither Latin nor Greek, the time saved being devoted to French and the sciences. At the end of the first cycle, normally reached when the pupil has turned fifteen, there is available the *certificat d'études secondaires du premier degré*. For the course is so arranged that it makes a complete whole, though it is also suited for those who are about to take up the second cycle. The A Division does not lend itself quite so well to this idea of a course definitely complete at fifteen as does the B Division. In the second cycle the three classes are the *seconde, the première*, and the final year, which has two parallel sections—the *classe de philosophie* and the *classe de mathématiques*. As to curriculum, the second cycle is arranged into four sections: (1) Latin and Greek, the main studies; (2) Latin, and a more advanced study of the modern languages; (3) Latin, and a more complete study of the sciences; (4) no Latin, but greater attention to modern languages and the sciences. The natural goal of the second cycle is the *baccalauréat*. There is, however, a *non-baccalauréat* course of two years for those who have finished the first cycle, and want to get a more 'practical' training in modern languages and in the sciences, particularly in their applications. These courses are found only in certain schools, and are so modified as to meet local needs.

OTHER EUROPEAN COUNTRIES.—Except in Russia, where probably not more than 10 per cent. of the whole population have had education of any kind, it may be said that in all the countries of Europe education at the primary stage is free and compulsory. Even in Spain, Portugal, Greece, Bulgaria, Roumania, Servia, and Turkey itself elementary education is at least nominally compulsory. In Italy there are two grades of elementary education—one extending from six years of age to nine; the other from nine to twelve. Wherever both are available, education is compulsory up to twelve; in other cases the limit of compulsion is nine. In almost all the European countries the educational system is centralised, and the cost is divided between the central and the local authority. In some cases, as in Austria and Belgium, the whole cost of primary education comes ultimately to be paid by the communes. Two exceptional cases deserve notice. In the Netherlands, by the act of 1887, public instruction was diminished in favour of private instruction, even at the elementary stage. This means that the state favours education

by private bodies, and gives support to them. Where no private schools are available it provides them on its own account, but it appears to prefer to subsidise private enterprise. Switzerland is an exception to the general rule about centralisation, and yet has one of the best systems of education in Europe. Education is free and compulsory, though the compulsion is not so strictly enforced in the Catholic cantons as in the Protestant. Higher education is specially good, there being seven universities, all independent. The only share the Federal government takes in education is in maintaining a somewhat famous polytechnic at Zurich.

UNITED STATES OF AMERICA.—From the earliest times education has been highly valued in the United States. At the very beginning the democratic ideal enforced the need of universal education. The administration of education is vested in the local and state authorities, and is not centralised as in the case of the great nations of Europe. There is a bureau of education at Washington, but its functions are limited to the dissemination of information. It has no power of control. While each state has its independent educational system, it is remarkable how uniform the general plan is throughout the Republic. At the earlier grades it may be said that education in America is compulsory and free, but somehow the compulsory aspect does not need to be emphasised there so much as in Europe. It is the general belief that public opinion is so strong on the subject, that except in the case of immigrants, it is not necessary to enforce attendance at school. There is indeed a tendency to leave school rather young, but it is generally maintained that the American knows too well the handicap of the lack of education to run any risks. Dr Stanley Hall, however, gives some very disquieting attendance statistics in his *Educational Problems*. The typical elementary and secondary course may be said to occupy twelve years—eight years for elementary and four years for secondary education. The elementary work is done in what is proudly called the common school, where the sons of all classes of citizens sit side by side. The high school provides a four-year course. The eight years at the elementary stages are commonly called grades, the first six being really elementary; the seventh and eighth being intermediary, and frequently called the grammar-school grades. American educators tell us that in the grammar-school grades, as compared with the primary, 'the emphasis is shifted from the mastery of the means of knowledge as a purpose to the mastery of knowledge itself.' There is certainly a tendency to cut out the grammar-school period, and to divide up the twelve years into two equal parts—six elementary and six secondary. But a determining factor will be the decision of the problem of the function of the high school. It is felt that at present the school course is unduly dominated by the demands of the universities, whither only a small proportion of the pupils go. It is complained that the pressure of the universities on the high schools is communicated by the high schools to the common schools, so that the education of the whole country is dominated by a goal that only a very small fraction reach. In Dr Arthur C. Perry's *Problems of the Elementary School* (1910) we find a diagram in which the elementary school is figured as representing 94 per cent. of those under education, the high school 5 per cent., and the university 1 per cent. We have here the German problem of the *einheits-schule* presented under a new aspect. The Americans have the *einheits-schule*, and are not sure that they like it. So far as the unity it implies is a social unity, they are well content (though it is ominous that a university president should have to defend the

common schools in an address entitled 'Call Nothing Common'); but when it comes to an educational unity, they begin to think that it might be better to have different kinds of schools according to the probable future of the pupils. The plan generally adopted in actual practice is to divide the twelve school years (6-18) into three periods: six years in the grades, three years at the junior high school, and three years at the senior high school. This supplies a vital articulation point at the age of 16. The junior high schools have established themselves in the confidence of the Americans as supplying a fitting terminus of a purely cultural training. Attention is now being mainly directed towards the organisation of the senior high schools as institutions for cultural training with a certain vocational bias.

Co-education is very general in America, and in spite of a fairly strong reaction it retains its hold. Objections come mainly from the east, and apply much more to the high schools than to the common schools. A more important problem of the same kind is the preponderance of women teachers. Up to the highest grades boys may be taught by women, and many Americans are wondering whether the result on the character of the boy is satisfactory. The kindergarten system has been thoroughly developed in America, and this, along with the predominance of women in the schools, is said to be producing an over-sensitive race.

America is more than usually well provided with universities. Many of these rank merely as good secondary schools would in Europe. If they would content themselves with the name of *college*, they would avoid unpleasant comparisons, and be recognised as the efficient institutions many of them are. In fact, French and German writers on education are inclined to suggest that there is room in the European system for the American college, somewhere between the *gymnasium* or *lycée* and the university. In any case, there are some thirteen or fourteen American universities quite on a level with our best European institutions, though differing considerably in type. With the exception of one or two universities in the east, they follow closely the type of the German, Scottish, and newer English universities. A marked feature of American education is the support it receives from philanthropic individuals. Institutions like the University of Chicago and that of Leland Stanford recall on a magnificent scale the generosity of pious founders who are almost extinct in England.

JAPAN.—We have in Japan one of the most striking examples of the deliberate adoption by a nation of a new system of education, embodying what it considers to be the best in foreign systems. The era of *Meiji*, or 'the Enlightened Government,' began in 1868, and under it the educational system was completely Occidentalised, the models being partly German, but mainly Anglo-Saxon. All children who have completed their sixth and have not yet completed their fourteenth year are said to be of school age, and must attend school, unless specially exempted, one of the recognised reasons for exemption being poverty. There is also a complete secondary and university system. At the earlier stages there were considerable numbers of foreign professors engaged by the government, but the policy is now being followed of having as much as possible done by Japanese. There is a complete system of ordinary and higher normal schools for the training of teachers. Physical education and hygiene are well attended to. Technical education receives special consideration, and it is here that most difficulty is found in securing proper teachers. All things considered, the higher education of girls is very satisfactory, and no doubt will develop rapidly. The text-books in the elementary schools

have given rise to a good deal of trouble through the dishonesty of publishers. Accordingly, the state has itself produced sets of text-books, and is taking all precautions that the standard thus set shall be maintained. The three foreign languages taught in the schools are English, German, and French. Since the Japanese regard English as the common language of the East, it greatly preponderates. In 1908 there were only two schools where German was taught exclusively, and seven in which the pupil might choose between English and another language. In all the other schools English was the only foreign language taught. It is also taught in the elementary schools, but the results are not yet very satisfactory on account of the poor qualifications of the teachers in this subject. However, improvement is taking place in this respect. Elementary education is free, but fees are charged in the higher elementary schools and for supplementary courses, though the fee may be remitted in the case of the poor. In the secondary schools, known as *middle schools* (whose purpose is 'to give a higher general education necessary for men'), tuition fees are levied, but are remitted in the case of those 'who are distinguished as specially worthy by their excellence in conduct and study.' Formerly those who had completed the higher elementary course were automatically admitted, if they desired, to the middle schools; but now the demand for admission is so great that a competitive examination has been instituted, and the age of leaving these schools, instead of being eighteen, as was intended, is now over nineteen. Middle schools are either public or private, there being about four public to one private. An excellent account of the subject is given by a former Minister of Education in Japan, Baron Kikuchi, in his *Japanese Education* (London, 1909).

BIBLIOGRAPHY.—(1) *Theory*.—Nearly all the German professors of philosophy during recent times have been expected to give a course on education; so we have the views of most of them on this subject—notably Kant, Hegel, Schleiermacher. Herbert went further, and in his *Allgemeine Pädagogik* (1806) and his *Umriss Pädagogischer Vorlesungen* (1835-41) elaborated a complete system. His educational writings have been Englished by the Felkins, and the whole Herbartian position is well put by F. H. Hayward, particularly in his *Critics of Herbartianism* (1908). In 1904 T. Raymont published his *Principles of Education*, and the consolidated educational theory of the present is now to be found in E. N. Henderson's *Principles of Education* (1910), F. E. Bolton's somewhat fuller, though less advanced, *Principles of Education* (1911), and J. Adams's *The Evolution of Educational Theory* (1912). One of the best presentations of an individual system is to be found in W. O. Bagley's *The Educative Process* (1905). T. P. Nunn's *Education, its Data and First Principles* (1920) deals admirably with recent developments. S. S. Laurie's *Institutes of Education* (1892) is the most systematic treatise in English. A. Bain's *Education as a Science* (1879) has had a great influence; and H. Spencer's *Education* (1861), though much criticised, is still a living force. G. Stanley Hall's *Adolescence* (1904) and *Educational Problems* (1911) are storehouses of matter that needs working up.

(2) *History of Education*.—K. von Raumer has a *Geschichte der Pädagogik* (Englished in 1863); so has K. Schmidt (1860-62). G. Compayré's *Histoire de Pédagogie* was Englished in 1886. Of English histories, T. Davidson's *History of Education* (1900) is good, but not so satisfactory as Paul Monroe's *Text-book of the History of Education* (1905). F. P. Graves has two excellent volumes, *A History of Education before the Middle Ages* and *A History of Education during the Middle Ages and the Transition to Modern Times* (1910). E. P. Cubberley's *History of Education* (1920) is a mine of information. For the classical period Paul Monroe has a *Source Book of the History of Education for the Greek and Roman Period* (1901). S. S. Laurie's *Pre-Christian Education* (2d ed. 1907), Mahaffy's *Old Greek Education* (1879), and Nettleship's famous article in Abbott's *Helvetica* are all valuable. For the Renaissance period W. H. Woodward's *Studies in Education during the Age of the Renaissance* (1906),

Vittorino da Feltre (1897), and Erasmus (1904) practically exhaust the subject. Supplementing A. F. Leach's *English Schools at the Reformation* is *The English Grammar Schools to 1600* (1908), by Foster Watson, whose *Beginnings of the Teaching of Modern Subjects in England* (1909) is full of unexpected facts. Later periods are excellently treated in J. W. Adamson's *Pioneers of Modern Education* (1903), and his *Short History of Education* (1920). Ch. Letourneau's *L'Évolution de l'Éducation* (1878) is a more or less scientific presentation of the history of education. Two syllabuses on the history of education are available—E. P. Cubberley's (1902) and W. J. Taylor's (1909).

(3) *History of the Administration of Education*.—The following will be found useful: Graham Balfour's *Educational Systems of Great Britain and Ireland* (2d ed. 1903); J. E. G. de Montmorency's *The Progress of Education in England* (1904); J. Kerr's *Scottish Education* (1910); J. Strong's *History of Secondary Education in Scotland* (1909); Sir J. K. Shuttlesworth's *Four Periods of Public Education* (1862); the very valuable series of *Special Reports* published by the Board of Education, edited up till 1903 by M. E. Sadler, whose volume on *Continuation Schools in England and Elsewhere* (1907) fills a gap in administrative history.

(4) *Books for Professional Teachers*.—The following volumes consist of series of articles by different writers, each dealing with the teaching of a subject in which he is a specialist. P. A. Barnett's *Teaching and Organisation* (1897); F. Spencer's *Aims and Practice of Teaching* (1897); J. Welton's *Principles and Methods of Teaching* (1906); J. W. Adamson's *Practice of Instruction* (1907); *The New Teaching* (1918), edited by J. Adams. E. Thring's *Theory and Practice of Teaching* (1885) is still of value. Works on Teaching are becoming rapidly specialised. Either an aspect of teaching is treated by itself, as in J. Adams's *Exposition and Illustration in Teaching* (1909); or a particular subject is selected for treatment, as in M. W. Keatinge's *Studies in the Teaching of History* (1910). Geography is treated in this way in separate works by Mackinder, Herbertson, Lyde, and Archer.

(5) *Encyclopaedias*.—Hitherto the standard work has been W. Rein's *Encyclopädisches Handbuch der Pädagogik* (2d ed. 1902); but the new *Cyclopaedia*, edited by Paul Monroe, in 5 vols., promises to surpass anything that has yet appeared in any language. P. Duissou's *Dictionnaire de Pédagogie* (1878) is particularly strong in history. Sonnenschein's *Cyclopaedia of Education* (3d ed. 1906) is handy, unpretentious, and very cheap. Pitman's *Encyclopaedia and Dictionary of Education* (4 vols. 1921) is edited by Professor Foster Watson.

(6) *Bibliographies*.—There are two American Bibliographies of Education—Hall and Mansfield's (1886; 2d ed. 1893) and W. S. Monroe's (1903). A very useful 'Bibliographical Note' appears in Laurie Magnus's *National Education* (1901). Useful lists of works on education are to be found also in Nelson's *Standard Books* (first vol. published 1911), and Sonnenschein's *Best Books* (first part of new ed. published 1911).

See also the articles UNIVERSITIES, RENAISSANCE, WOMEN'S RIGHTS; those on Oxford, Cambridge, Edinburgh, Dublin, Harvard, and other universities at home and abroad; Newnham, Girton, Queen's College; on the greater colleges and schools (Eton, Harrow, &c.); those on the great educators (Colet, Comenius, Pestalozzi, Froebel, &c.); ARMY SCHOOLS, ART, CONSERVATOIRE, GYMNASIUMS, KINDERGARTEN, SLOYD, &c.

Edward THE ELDER, eldest son of King Alfred, reigned c. 901-c. 925. He conquered the Danish parts of England as far as the Humber, permanently united all southern and central England, was acknowledged by the Welsh kings, and, according to tradition, was chosen by the Scots 'to father and lord.' See ENGLAND.

Edward THE MARTYR, son of Edgar (q.v.), ruled from 975 to 979 with the support of Dunstan (q.v.), being murdered at Corfe Castle by his step-mother's orders.

Edward, surnamed the CONFESSOR, the last Anglo-Saxon king of the old royal line, was born at Islip in Oxfordshire, the elder son of Etheled the Unready, by his marriage in 1002 with Emma,

daughter of Richard the Fearless, duke of the Normans. On the death of Ethelred in 1016, Canute obtained possession of the throne, and next year married the widowed Queen Emma, by whom he had two children, Gunhild and Hardicanute. Until the death of Canute in 1035, Edward lived in Normandy, but was invited to his court by his half-brother Hardicanute in 1041, and next year succeeded him as king. This was brought about mainly by the great Earl Godwin, whose only daughter, Edith, Edward married in 1045, to treat her, however, throughout his life rather like a father than a husband. He was perpetually influenced by his favourites, who were usually worthless foreigners, and the history of his reign is merely the record of the struggle of the Norman or court party with the national or Anglo-Saxon party, which was led by Godwin and his son Harold. Wars with the Welsh, and an unsuccessful revolt of the Northumbrians, were the chief events in the later years of his reign. Edward died 5th January 1066. He was a poor and spiritless king, who, for his monk-like virtues, was canonised by Pope Alexander III. in 1161. With him the old English monarchy perished, save only for its spasm of dying energy in the few months' reign of the heroic Harold. See Freeman, and the early lives of Edward edited by H. R. Luard ('Record' series, 1858).

Edward I., king of England, was the elder of the two sons of Henry III., by his queen, Eleanor, daughter of Count Raymond Berenger of Provence, and was born at Westminster, June 17, 1239. His name was given him by his father out of reverence for the memory of Edward the Confessor, and in its English sound, as well as in the honest English temper, no less than the yellow hair and stalwart figure with which the young prince grew up, Englishmen might well have read the promise, that once more after two hundred years England would be ruled by a native English king. Edward was brought up at Windsor, was given by his father in 1252 the government of Gascony, and in 1254 married, in the monastery of Las Huelgas, Eleanor, sister of Alfonso X. of Castile, receiving immediately thereafter from his father Gascony, Ireland, and the Welsh march betwixt the Conway and the Dee, where, in fighting with the turbulent Welshmen, he learned his first lessons in warfare. At the Parliament of Oxford (1258) he took part with his father in his contest with his troublesome nobles, but thereafter appears to have at first sided with the great Earl Simon de Montfort, the leader of the barons or national party, without, however, impairing his own personal loyalty and affection for his father, with whom ere long he was reconciled. It was his rash eagerness in pursuing an advantage gained over the Londoners, who were devoted to the party of Simon, that lost the battle of Lewes (1264), one immediate consequence of which was the prince's imprisonment as a hostage for his father's pledges. Conditions for his liberation, discussed at Simon's famous parliament of 1265, were frustrated through Edward's escape by a stratagem from Hereford Castle; and at the final battle at Evesham (August 4), where Simon recognised, in the skilful disposition of his enemy's forces a fatal lesson learned from himself, the struggle practically ended with the great popular champion's death on the battlefield. Edward gained much influence by the wise prudence and moderation with which he stamped out the last embers of rebellion.

In 1270 he started at the instigation of Louis IX. of France to join the last of the crusades, but when he reached Tunis, found that king dead, and the expedition already desperate of success. He went on to Acre, and won great renown as a knight, but failed to save the Frankish king-

dom in the East from its inevitable fate. In June 1272, while sitting alone on his bed, his own strength and energy saved him from being murdered by one of the infamous sect of the Assassins. Hastily guarding himself with his arms, and receiving a desperate wound, from which he afterwards suffered much, he tore the knife from his assailant's hand, and buried it in his heart. The ancient story that his queen Eleanor, who had followed him in his pilgrimage, saved his life at the risk of her own by sucking the poison from the wound, unfortunately lacks historical support, but fits well with the romantic temper of the times, as well as with the deep affection that survived throughout life betwixt husband and wife. Two months later he started for home, and at Capua, in the January of 1273, heard of his father's death two months before. Meantime he had been quietly proclaimed king, and as things went well in England, he visited the pope, did homage at Paris for his French provinces, and did not return to his kingdom till the August of 1274. At his coronation he received the homage of Alexander III. of Scotland for his lands in England, but Prince Llewelyn of Wales neglected the summons to attend, and only did his homage in 1276, under the combined terrors of excommunication and the royal army. Edward at once commenced that wise and large policy of domestic consolidation and financial as well as legal reform that has shed such lustre upon the reign of the English Justinian, and made it almost the most important epoch in the constitutional history of England.

His first warfare was with the turbulent and disaffected Welshmen, who had profited by the intestine turmoil of the preceding reign, and intrigued perpetually with the rebellious nobles of Henry III. for their own ends. The forced peace of 1277, and the national dissatisfaction at the stringent terms granted by Edward, which was not abated by the personal favours he heaped upon the princes Llewelyn and his brother David, were but the prelude to the final struggle which commenced three years later, and ended in the complete suppression of Welsh nationalism, with the defeat and death of Llewelyn, near Builth in Brecknockshire, and the cruel execution of David at Shrewsbury, as a traitor, in 1284. By the famous Statute of Wales in the same year, the ancient principality was finally annexed to the English crown, while English laws and English institutions were forced upon the conquered people. Edward devoted the next year to legislation, then went abroad to mediate, without success, in the quarrel between France and Aragon. He had soon to return to quell fresh disturbances in Wales, and even in England, where the great Statute of Winchester, which had been passed in 1285 to place the defence of the country on a really national basis, had not yet had time to effect its end. Finding that most of his judges had been corrupting justice, he punished them with an iron hand, next banished in 1290 all the Jews to the number of over 16,000 from the kingdom on the plea of extortionate usury. Earlier in the reign he had hanged 280 for money-clipping and forgery.

Just at this time the death of the young Scottish queen, the Maid of Norway, whom Edward had caused to be betrothed to his eldest surviving son, Edward of Carnarvon, opened up a fatal contest for the Scottish crown, which gave Edward his opportunity to assert anew the old but somewhat shadowy claim of the English crown to the overlordship of Scotland. The southern half of that composite kingdom was inhabited by people of English blood and English institutions; its south-eastern part, the Lothians, had undoubtedly once formed part of the Anglian kingdom of Northumbria; while its south-western, Strathclyde or Scottish Cumbria, the population of which

was in great part Celtic, had in 945 been given by the English king Edmund I. to Malcolm as a fief. The northern portion of the kingdom was purely Celtic in blood, and had at no time been subject to English influences, but though the reigning family was itself of Celtic origin, its authority hardly extended effectively beyond the region inhabited by men of English blood. Undoubtedly the Scottish king in 921 chose Edward the Elder 'to father and to lord,' and the right then acknowledged was claimed successively by William the Conqueror, Rufus, and other English kings. Moreover, from the 12th century it had been customary for the Scottish kings or their sons to receive English earldoms, and do homage for them, but it continued to remain somewhat vague, whether such homage was understood to be extended beyond these earldoms, so as to include the Lowland provinces and the whole Scottish kingdom. William the Lion, taken prisoner at Alnwick in 1174, for his freedom acknowledged the supremacy of Henry II. in the treaty concluded at Falaise on December 7, but on his return found his subjects ill disposed to accede to his cowardly submission; and fifteen years later the claim founded on this special act of submission was formally renounced for a sum of 10,000 merks by Richard I., who was eager to raise money for his crusade. Such was the ill-defined position of this ancient controversy, when fate seemed to fling into Edward's hands the opportunity of defining it anew with all the clearness dear to his legal mind. It was easy for him to secure a recognition of his superiority from the selfish and eager candidates for the crown, and meantime he secured the Scottish castles, and after a deliberate examination of the rival claims, decided in favour of John Balliol, who, on his accession, paid homage distinctly for the whole kingdom of Scotland. He soon found his position as a vassal-king intolerable, betwixt the unruly turbulence of his subjects and the imperious demands of his over-lord, who allowed appeals to be led from Balliol's subjects to himself. Meantime the ambitious projects of the new king of France, Philip IV., involved Edward in anxieties for the safety of Guienne and his other possessions in France. Ere long the high-handed conduct of the French king made war necessary, and Edward, with characteristic energy, at once began his preparations, and summoned in 1295 an assembly of the estates of the realm, which was practically the beginning of our modern parliaments. The ever-increasing exasperation of the Scots at length broke out into open warfare in 1296. Edward at once marched northwards, captured Berwick, and carried his victorious arms as far north as Aberdeen, Banff, and Elgin, taking the great castles on the way, formally accepted Balliol's surrender of the crown at Montrose, and returned to Berwick (August 22), carrying with him the famous coronation-stone from Scone, after having subdued the whole kingdom in about five months. Here, six days later, he received the fealty of the clergy, barons, and gentry of Scotland, whose names fill the thirty-five skins of parchment known as the Ragman Roll.

At length he was at liberty to turn to France, but the great cost of his late expenditure had already driven him to make such heavy demands upon the revenues of the church, that the clergy now refused fresh subsidies, headed by Archbishop Winchelsea and supported by the bull 'Clericis Laicos' of Pope Boniface VIII. The king retaliated by placing the clergy of the kingdom in outlawry. At the Salisbury parliament in February 1297, the great barons also refused to take part in foreign war, while the merchants were exasperated because their wool had been seized. A com-

promise was soon effected with the clergy, and a temporary illegal grant for the immediate purposes of the war was procured from the nobles and commons who were with him. Edward sailed for Flanders, and at Ghent confirmed the Charter with such supplementary clauses as were demanded by his refractory nobles, thus finally establishing the right of the people themselves to determine taxation. This is only second in importance to Magna Charta itself as a landmark in the history of England. The suspicious fears of his people compelled Edward to repeat the confirmation at London in 1300, and again at Lincoln in 1301—an insult to his honesty which the king never forgave, and to which his subsequent banishment of Winchelsea was due. In 1303, and again the year after, Edward, in desperate straits for money, levied, by agreement with the foreign merchants, some new customs—the beginning of our import duties—without consent of the estates, and collected a *tallage* from the royal demesne, and again, in 1305, he obtained from Clement V. a formal absolution from the obligations of 1297. It is true that the first two measures were contrary to the spirit rather than the letter of his promise, and that he never sought to avail himself of the dangerous power granted him by the papal absolution, yet these three facts, says Bishop Stubbs, 'remain on record as illustrations of Edward's chief weakness, the legal captiousness, which was the one drawback on his greatness.'

It was the dangerous aspect of affairs in Scotland that forced the king to submit so easily to the demands of his barons. Already, in the spring of 1297, Wallace, without any countenance from the Scottish nobility, had commenced a guerilla warfare, and his handful of desperate men soon increased into an army, which completely defeated Earl Warenne and Cressingham at Cambuskenneth (Stirling Bridge) in September 1297, and ravaged England, with the most atrocious cruelties, from Newcastle to Carlisle. Edward's expedition to Flanders had been a failure, but he hastened to conclude a truce, so as to find time to chastise the Scots, cementing it by his betrothal to Philip's sister Margaret. The good Queen Eleanor had been already dead nine years. Meantime, Wallace's success had merely earned him the bitter jealousy of the Scottish nobles, and his power was finally broken in the disastrous defeat by Edward's army at Falkirk in July 1298. The king had two of his ribs broken by a kick from his horse on the morning of the battle, but rode throughout the day as if unhurt. The struggle lingered on some years under various leaders, as Edward found his energy paralysed the while by the intrigues of Philip, and the constitutional struggles with his barons. Pope Boniface, in 1301, put forth a claim to the overlordship of Scotland, which was repudiated by the whole body of the estates at Lincoln. It was not till the June of 1303 that the king was able to resume his conquest. Accompanied by a fleet carrying his supplies, he penetrated again into the far north, tarried a while in Dunfermline, and settled the kingdom after the reduction of Stirling, the last place of strength that held out. In 1305 Wallace was betrayed into his hands, sent to London, and cruelly executed as a traitor. The fate of this noble-hearted patriot is a fatal blot upon his conqueror's memory, but it should not be forgotten that Edward was profoundly convinced of the legality of his own claims over Scotland, and that Wallace to him was merely a pestilent rebel, who had earned his doom by treason to his lord and by the cruelties he had inflicted upon Englishmen. The same year the king prepared a new constitution for the conquered kingdom, divided it into sheriffdoms like the English counties, and made arrangements for the representation of the Scots in

the English parliament—a measure which, had it been successful, might have anticipated by four centuries the benefits of the union. It might now have been expected that Scotland was effectively subdued, but ere long Robert Bruce, who had hitherto played a dubious game, raised a revolt in the beginning of 1306, got rid of the regent Comyn, his most serious rival, by a foul murder in Dumfries church, was crowned king at Scone, and kept up an incessant but varying struggle during the winter of 1306 and the spring of 1307. The treachery of those who had sworn fealty to him, and whom he had trusted implicitly, roused Edward to the pitch of exasperation, and at the knightings of Prince Edward at Westminster, he swore a solemn vow to be revenged upon Bruce. He at once despatched a force to Scotland, and though now old and infirm, began preparations for his fourth expedition; but he was attacked with dysentery on the march, and his malady increased so much upon him that he died on the 7th of July 1307, at Burgh-on-Sands, near Carlisle, within sight of Scotland, leaving for his son Edward the dying command not to bury his body till he had utterly subdued the Scots, but to carry his bones with the army until the victory was complete. Eleven days later the young prince reached Carlisle, but returned a few weeks after to London, and buried his father's body in Westminster, where it still rests under a slab, with the simple but truly descriptive inscription: 'Eduardus primus, Scotorum malleus, hic est.'

See Seeley's *Life and Reign of Edward I.* (1871); vol. ii. (1876) of Bishop Stubbs's *Constitutional History of England*, his *Early Plantagenets* in 'Epochs of Modern History' (1876), and his prefaces to the *Reigns of Edward I. and II.* in the 'Rolls' series (1882-83); and T. F. Tout's monograph (1893).

Edward II., son of the preceding, was born at Carnarvon in Wales, 25th April 1284, and in 1301 was created Prince of Wales, being the first heir-apparent of the English throne who bore that title. In 1297 he was appointed regent in his father's absence, and as such signed the famous *Confirmatio Cartarum*. He accompanied his father on his various expeditions into Scotland, but was absent at his death in July 1307, and instead of carrying out his dying commands, returned to London to give himself to unworthy pleasures and the beloved companionship of his favourite the Gascon, Piers de Gaveston. A month later he created him Earl of Cornwall, and on his departure for France in the beginning of 1308 to marry Isabella, daughter of Philip IV., left him guardian of the kingdom. The indignant nobles demanded his banishment, and twice was the favourite forced to leave England, but as often was he recalled by the infatuated monarch, until at length they rose in arms, captured Gaveston, and executed him at Warwick in 1312. Two years later, Edward invaded Scotland at the head of an army of 100,000 men. At Bannockburn, on the 24th June 1314, he was defeated with immense slaughter by Bruce, whose heroism redeemed the dubious patriotism of his earlier years, secured his own crown, and the final independence of his kingdom. With the capture of Berwick in 1318, he had undone every trace of the conquest of Edward I. This great disaster in Scotland was followed by risings in Wales and Ireland, and two seasons of unexampled famine attended by still more fatal pestilence. From this time till 1322 the influence of Lancaster as the king's minister was supreme, but in that year, with the aid of his new favourites, Hugh le Despenser the elder, and his son, Hugh the younger, who had been already banished, but whom the king had recalled, Edward overthrew Lancaster, and put him to death. Immediately after, Edward invaded Scotland for the last time, but achieved no particular success, and

in 1323 concluded a truce with that nation for thirteen years, and returned to England. A dispute now arose between him and Charles IV. of France, brother of his wife Isabella, in regard to the territories which he held in that country. Charles seized these, whereupon Edward sent over Isabella to remonstrate, and, if possible, to effect an amicable arrangement between them. Isabella already despised her husband, and hated the Despensers, and had contracted a guilty passion for Mortimer, one of the most unprincipled and powerful of the disaffected nobles. She now treacherously made common cause with many of the exiled nobles against her husband and the Despensers, and having obtained possession of the young Prince Edward, she embarked from Dort, in Holland, with a large body of malcontents, and landed on the coast of Suffolk on the 24th September 1326. Edward fled, but was taken prisoner in Glamorganshire. The Despensers, father and son, were executed, and the monarch himself compelled formally to resign the crown. His robust frame refusing to succumb to some months of the most inhuman treatment, he was murdered by a cruel death in Berkeley Castle, 21st September 1327.

Edward III., son of the preceding, was born at Windsor, 13th November 1312, and was crowned king 29th January 1327. During his minority the country was governed nominally by a council of regency, but really by Mortimer and his paramour Isabella. Early in 1328 the young king married Philippa of Hainault, and two years later seized Mortimer and put him to death, banishing his unworthy mother, Isabella, to her remaining twenty-seven years of privacy in Castle Rising. He next invaded Scotland to assist Edward Balliol, son of John Balliol, who, in the confusion that ensued on the death of the great Bruce, had made a descent on the country, and got himself crowned at Scone. In a bloody battle fought at Halidon Hill, near Berwick, 19th July 1333, the Scots were completely defeated, whereupon Balliol assumed the authority of a king, and did homage to Edward for his possessions, but a few months later had to flee from the kingdom. In the course of three years Edward thrice invaded Scotland, but though he frightfully wasted the country, and brought armies such as could not be met in the field, he could not break the invincible spirit of the people, who, after each invasion had rolled over them like a flood, rallied anew with a still more stubborn resolution to be free. But the scene of Edward's great exploits was France. Charles IV. having died without a son, Philip of Valois, the nearest heir by the male line, ascended the throne, under the title of Philip VI. Edward claimed the crown in right of his mother Isabella, sister of Charles; but as the law of France expressly excluded females from enjoying sovereign rights, it is needless to say that his claim was utterly groundless. The English king admitted that his mother, being a female, could not inherit the crown of France, but affirmed that he, as her son, might. But it is clear that he could not receive from his mother rights to which she herself had no claim. Yet never was a bad cause redeemed from baseness with more splendid triumphs. Edward declared war against Philip in 1337, raising money unsparingly by tallages, forced loans, and seizing wool for which it is true he promised to pay in the course of two years. Spite of the brilliant sea-victory at Sluys in 1340, the war was at first singularly unsuccessful, and Edward soon found himself at issue with his nobles, and especially the princes of the church, and was compelled to purchase the grants of money necessary for the war with concessions of privileges, which he occasionally endeavoured to evade by subterfuges that his

grandfather would have scorned. At length in 1346, accompanied by his eldest son, known as the Black Prince, he again invaded France, conquered a great part of Normandy, marched to the very gates of Paris, and on the 26th August 1346, inflicted a terrible defeat on the French at the famous field of Crécy. Here the Black Prince, though but sixteen years old, exhibited the most heroic courage. After some further successes, and the fall of Calais after a twelvemonth's siege, a truce for a few months was concluded between the two nations, afterwards from time to time extended. Just before the surrender of the famished citizens of Calais, occurred the heroic incident of Eustace de St Pierre and his five companion burgesses of Calais, who offered themselves as victims to the king's fury to save their fellow-citizens, and were saved only at the impassioned entreaties of Queen Philippa. Meanwhile the Scots had sustained in 1346 a severe defeat at Neville's Cross, near Durham, their king, David II., being taken prisoner, while in 1349 the terrible Black Death had carried off a third of the total population of England, and permanently changed the whole relations between labourer and master.

The war began anew in 1355, and next year, on the 19th September, the Black Prince obtained a brilliant victory at Poitiers, where King John of France was taken prisoner. The Scottish monarch was released under promise of a ransom of 100,000 marks in 1357, and King John in 1360, when a peace was concluded between the French and the English, by which the latter were to retain their conquests. King John, finding it impossible to raise his proposed ransom, honourably returned to captivity, and died in London in 1364. Shortly before this date, David, king of Scotland, whose residence in England had extinguished the little patriotism he ever had, entered into a secret agreement with Edward, in virtue of which his kingdom, if he died without male issue, was to be handed over to the English sovereign. Meanwhile, the Black Prince, who had married Joanna, daughter of the Earl of Kent, had received from his father Aquitaine and Gascony, and ruled there for some time very prosperously; but ultimately involving himself and his father in a war with France, which was disastrous in its issues, was obliged in 1374 to conclude a truce for three years. Edward waged war no more. In spite of his brilliant victories, in spite of the dazzling valour of his son, he was at the last unsuccessful. Under him, says Mr Freeman, 'England was successful in battles, but she was thoroughly beaten in war.' Neither in Scotland nor in France did he realise his desires. Affairs at home were no less unsatisfactory in the last years of his life, and public finance drifted hopelessly into ruin. He quarrelled with his parliaments, and saw public discontent sap the loyalty of his people, while he gave himself up to the influence of his rapacious mistress, Alice Perrers, and let the government slip into the hands of his third son, John of Gaunt. The Black Prince, who had headed a party opposed to his father's policy, died 8th June 1376, and the king himself expired almost alone on the 21st June 1377, after a reign of fifty-one years.

See Longman's *Life and Times of Edward III.* (1869), Warburton's *Edward III.* (1875), Mackinnon's *History of Edward III.* (1900).

Edward IV., son of Richard, Duke of York, and Cicely Nevill, daughter of the first Earl of Westmoreland, was born at Rouen in 1442, and brought up at Ludlow Castle, being known during his father's lifetime as Earl of March. The Yorkist claim to the crown will be discussed under **ROSES (WARS OF THE)**; here it is enough to say that Edward found himself, on his father's defeat and

death at Wakefield (December 30, 1460), head of a strong and resolute party. With characteristic vigour he at once set out from Gloucester, won the battle of Mortimer's Cross (February 2, 1461), lost in the person of Warwick the second battle of St Albans fifteen days later; but only nine days thereafter, taking advantage of the reaction of the south against the excesses of Queen Margaret's victorious northern soldiers, entered London in triumph, and was hailed as king. A month afterwards he secured for himself the crown by the great battle of Towton, near York. The indefatigable queen, with the aid of French money, kept up the struggle in the north, but her defeats at Hedgeley Moor and Hexham (1464), and the capture of the unhappy King Henry (1465), in the meantime closed the door upon her hopes. The young Edward was handsome and frank in manners, and quickly became a most popular king. The commons granted him the wool-tax and tonnage and poundage for life. But Edward imperilled his popularity by his uncontrolled licentiousness, and by his ill-advised and at first secret marriage (1464) with Elizabeth Woodville, the handsome daughter of the Lancastrian Lord Rivers, and widow of Sir John Grey of Groby, displeased the great Earl of Warwick and many of his nobility, who had hoped to buttress the king's throne by a French or Burgundian alliance, and whose disaffection was further increased by the honours which were lavishly heaped upon the young queen's upstart relations. Warwick succeeded in detaching the king's brother, the Duke of Clarence, from his side, and made him his own by marrying him to his daughter Isabel. Meantime the tide of popular feeling showed the direction in which it was running by insurrections in the northern counties and in Lincoln. At length Warwick finding Clarence too weak a foundation on which to build a Yorkist revolt, crossed to France, and there made friends with his ancient enemy, Queen Margaret, and cemented the alliance by marrying his daughter Ann to her son, Prince Edward. In September 1470 Warwick landed in England, and Edward finding himself deserted on every side fled to Flanders; six months later he landed at Ravenspur, and pressed on to give battle to Warwick. His brother Clarence went over to his side, and in the final battle at Barnet, on Easter-day, April 14, 1471, the kingmaker fell on the field of his defeat. Edward next turned to meet Queen Margaret, and put an end to the war by the victory at Tewkesbury (May 4). He showed the savagery of his nature by the murder of the young Prince Edward, and the ruthless severity of his vengeance upon the other captives, some of whom had left sanctuary on promise of their lives being spared. The night of his arrival in London the old king, Henry VI., died in the Tower—of a broken heart as was given out. Edward henceforward sat securely on his throne, and used his power freely to extort money from his subjects by forced loans. In 1478 he stained his name by the private execution in the Tower of his brother Clarence—drowned according to an old tradition in a butt of Malmsey wine. Edward's partisanship of Burgundy against France had brought no glory to his army, the leaders of which were induced by French gold to abandon the war. Equally unsuccessful were his ambitious schemes for the marriages of his five daughters. Edward died suddenly, April 9, 1483, worn out before his time by his debaucheries.

See Gairdner's *Houses of Lancaster and York* (1874) his Introductions to the *Paston Letters* (1872-75); Stratford's *Edward IV.* (1910); and Miss Scofield's (1923).

Edward V., son of the preceding, was born 4th November 1470. The story of his life is brief and tragic. At the death of his father, he was living

at Ludlow in Shropshire. When the news reached Ludlow, Earl Rivers, his maternal uncle, set out with him for London. Richard, Duke of Gloucester, however, contrived to obtain possession of his person at Northampton, and brought him to the capital himself, in May 1483. Towards the end of the same month Richard was appointed Protector of the kingdom. In June the young Duke of York, Edward V.'s brother, also fell into his hands. The two hapless boys were then removed to the Tower, and were never more heard of. In 1674 some bones were discovered below the stairs which led to the White Tower chapel, and were reinterred as the princes' remains in Westminster Abbey in Henry VII.'s chapel. There is no doubt that they were murdered by their uncle Gloucester, who himself began his short reign as Richard III., July 6, 1483.

Edward VI., born at Hampton Court on 12th Oct. 1537, was Henry VIII.'s son by his third queen, Jane Seymour, who died twelve days after his birth. Till he came to six years he was brought up 'among the women'; then his instruction commenced 'in learning of tongues, the Scriptures, philosophy, and all liberal sciences.' Cheke and Ascham were among his preceptors. On 21st Jan. 1547 he succeeded Henry, when Edward Seymour, Earl of Hertford, his uncle, got himself made Protector. A *novus homo*, who from a country gentleman had risen to be ruler of England through his sister's queenship, Seymour allied himself with the reformed party against the nobles of the old régime, and sought by some high achievement to justify his rapid exaltation. During the first year of his protectorate he invaded Scotland, to enforce the marriage-contract between Edward and Mary, Queen of Scots. In the battle of Pinkie (10th Sept. 1547) the Scots were utterly defeated, and Scotland lay at the mercy of Seymour, now self-created Duke of Somerset; but his presence was needed at home. He returned to find that his brother, Lord Seymour, the admiral, had been caballing against him. Somerset had him attainted; and on 20th March 1549 he was sent to the block, the boy-king consenting coolly to his death. That summer witnessed two rebellions—of Catholics in Devon, and of agrarian malcontents, under Ket the tanner, at Norwich. Both were suppressed; but two months afterwards a more formidable adversary arose in the person of Ket's vanquisher, John Dudley, Earl of Warwick, who worked the Protector's downfall by insinuations against him of 'ambition, vain-glory, and self-enrichment' (such are the entries in Edward's Journal). Somerset was lodged in the Tower, pardoned, assailed anew, and this time beheaded (22d Jan. 1552). Dudley meanwhile being created Duke of Northumberland. The people regretted with good reason Somerset, for Dudley was both a worse and a weaker man. Indifferent in matters of religion (though he died a professed Catholic), he too let the Reformation take its course under Cranmer (q.v.) and Cranmer's more headstrong colleagues; his single aim was to secure the succession for his own family. With this view he married his fourth son, Lord Guildford Dudley, to Lady Jane Grey, daughter of that Duchess of Suffolk to whom by the will of her uncle, Henry VIII., the crown was to pass in default of issue by Edward, Mary, or Elizabeth. Northumberland now worked upon the dying boy to exclude his sisters and nominate Lady Jane as his successor. Edward consented; and a 'device' thus settling the succession, was drawn up. The king lived only a few weeks after, dying at Greenwich on 6th July 1553, of poison it was rumoured, but more probably from the effect of quack nostrums on a consumptive frame. On 8th August he was buried in Westminster with Protestant rites, but mass of requiem was chanted in the Tower. A truer estimate of

him—shrewd, cold, a very Tudor—may be formed from Prof. A. F. Pollard's summing up (*Political History of England*, vol. vi. 1910) than from Sir C. Markham's *Edward VI.* (1907).

Edward VII., eldest son of Queen Victoria, was born at Buckingham Palace, 9th November 1841, and christened Albert-Edward. After a careful education under four private tutors, he studied at the universities of Edinburgh, Oxford, and Cambridge. In 1860 he visited the United States and Canada; in 1862 travelled with Dean Stanley in the East; and on 10th March 1863 married the Princess Alexandra (born 1844; died 1925), eldest daughter of Christian IX. of Denmark. Besides three daughters, two sons were born of this marriage—the eldest, Prince Albert-Victor-Christian-Edward, Duke of Clarence (born 8th January 1864; died 14th January 1892), and George, Duke of York and Prince of Wales (born 3d June 1865; created Duke of York, May 1892; succeeded as George V. on the death of his father). Recovery from a six weeks' attack of typhoid was celebrated in St Paul's on 27th February 1872 with great enthusiasm—an enthusiasm emulated in the East on the occasion of a visit to India (1875-76). The King, the first British monarch of the Saxe Coburg house, was a Field-marshal, and in 1874-1901 Grand-master of the Freemasons; and he constantly manifested a lively interest in exhibitions, charitable institutions, the housing of the poor, agriculture, and the well-being of the people. For the Queen his mother, he, then Prince of Wales, bore much of the burden of court ceremonials and public functions. He assisted in promoting the Royal College of Music; and the Imperial Institute was due to his suggestion. On 4th April 1900 he was shot at by a young anarchist, Sipido, in a train at Brussels; on 22d January 1901 he succeeded his mother as Edward VII. His coronation, arranged for the 26th June 1902, but postponed on account of a surgical operation, was celebrated with traditional splendour in Westminster Abbey on the 9th August 1902. He contributed greatly to the restoration of cordial relations with France, and at his death (6th May 1910) had conciliated at home and abroad universal respect for his political insight, tact, and kingly dignity. See *Life* by Sir Sidney Lee (vol. i. 1925).

Edward THE BLACK PRINCE, eldest son of Edward III. and Philippa, was born at Woodstock, 15th June 1330, and was created Earl of Chester (1333), Duke of Cornwall (1337), and Prince of Wales (1343). Knighted by his father at La Hogue in 1346, he the next month, mere boy though he was, fought bravely at Crécy, and is said to have won from his black armour his popular title—a title, however, first cited in the 16th century. In 1355-56 he undertook two marauding expeditions in France, the second signalised by the great victory of Poitiers, where King John and his son Philip were taken prisoners. In 1361 he married his cousin, Joan, the 'Fair Maid of Kent' (1328-85), who bore him two sons, Edward (1365-70) and the future Richard II.; in 1362 his father created him Prince of Aquitaine, and next year he departed to take possession of his principality. In 1367 he espoused the cause of Pedro the Cruel (q.v.), and at Navarrete won his third great victory, taking Du Guesclin prisoner; in 1370, worn out by sickness, he sacked Limoges with merciless severity. He died at Westminster, 8th July 1376. See *Lives* by G. P. R. James (1822), Le Poittevin de la Croix (1854), L. Creighton (1876), Dunn-Pattison (1910).

Edward, THOMAS (1814-86), the 'Banff naturalist,' son of a private in the Fife militia, was born at Gosport, and spent his early years at Aberdeen. After settling as a shoemaker in Banff in 1837, his

passion for natural history led him to collect many specimens and discover new species, which he classified, described, and exhibited. He was a Fellow of the Linnean Society. *Smiles's Life of a Scotch Naturalist* in 1876 awakened much sympathy, and a pension was given him of £50 a year.

Edwardes, Sir Herbert Benjamin, was born at Frodesley in Shropshire, 12th Nov. 1819. Entering the army of the East India Company in 1840, he was, on the outbreak of the first Sikh war (1845), appointed on the staff of Sir Hugh Gough, and fought at Mudki and Sobraon. As assistant to Sir Henry Lawrence, British resident at Lahore, he took an active share in punishing the Dewan Mulraj of Multan, who had murdered Mr Vans Agnew and Lieut. Anderson, defeating him twice, and capturing his city (1849). During the Indian Mutiny, Edwardes, as commissioner of the Peshawar frontier, did good service by conciliating Dost Mohammed of Afghanistan, and securing his neutrality. In 1865 ill-health obliged him to return to England, where he commenced to write a *Life of Sir H. Lawrence*, which was completed after his death (at London, on 23d Dec. 1868) by Herman Merivale. He also wrote *A Year on the Punjab Frontier in 1845-49*.

Edwards, Amelia Blandford, was born in London, 7th June 1831. Her first novel, *My Brother's Wife* (1855), was followed by a dozen others, among them *Debenham's Vow* (1869) and *Lord Brackenbury* (1880). She also published a volume of *Ballads* (1865), and, besides books of holiday travel in Belgium and the Dolomites, *A Thousand Miles up the Nile* (1877). Miss Edwards was the founder and honorary secretary of the Egyptian Exploration Fund, and wrote many papers on Egyptology. She died 15th April 1892. —Her cousin, **Matilda Barbara Betham-Edwards** (1836-1919), was born at Westerfield, Ipswich, and when quite a young girl attracted the notice of Charles Dickens, who published her poem, 'The Golden Bee,' in *All the Year Round*; it is included in her poems (1885). Her first novel, *The White House by the Sea*, appeared in 1857, *Dr Jacob* in 1864, and *Kitty* (described by Lord Houghton as 'the best novel he had ever read') in 1869. She also published *A Winter with the Swallows* (1867), *A Year in Western France* (1875), *Home Life in France* (1905), *Literary Rambles in France* (1907), *Mid-Victorian Memories* (1919), and edited Murray's *Southern, Eastern, and Central France*, and Young's *Travels* (1899).

Edwards, Milne. See **MILNE-EDWARDS**.

Edwards, Jonathan, was born at East Windsor, Conn., 5th Oct. 1703, only son of Timothy Edwards, clergyman there for more than sixty years. The boy, precocious alike in learning and piety, graduated at Yale College in 1720; his doubts had given way to 'an inward sweet delight in God.' After acting as tutor at Yale from 1724 to 1726, he was ordained in 1727 colleague to his maternal grandfather, Solomon Stoddard, in his ministry at Northampton, Mass. Two years later the death of the latter left him alone, and here for nearly twenty-four years he laboured with remarkable earnestness, guiding his flock through the excitement of a revival begun by the preaching of George Whitefield in 1740. The happiness of his ministry was after seventeen years broken by a bitter dispute with his people about the circulation of immoral books, and about returning to the earlier Congregational rule of refusing to admit to communion persons not consciously converted. Edwards supported the more rigid views, and was obliged to resign his ministry in 1750. He next laboured as missionary to the Housatonnuck Indians in Massachusetts until 1758, when he was called to succeed his son-in-law,

President Burr, of Princeton College, but died of smallpox only thirty-four days after his installation, 22d March 1758. Edwards is one of America's most original thinkers in metaphysics, and his treatise on the *Freedom of the Will* (1754) has never been superseded (see **WILL**). He was a rigid Calvinist in theology, but his heart was warmed with a piety of rare saintliness and elevation. His other works include *Original Sin* (1758), *True Nature of Christian Virtue* (1788), and *Dissertation on the End for which God created the World* (1789). The most notable adherents of his school were Samuel Hopkins (q.v.); his son, Jonathan Edwards; Joseph Bellamy of Connecticut (1719-90); Nathaniel Emmons (1745-1840); Timothy Dwight (q.v.); and Leonard Woods, professor at Andover—almost all of whom wrote copiously. There have been many editions, more or less complete, of the works of Edwards, that by Dwight (with a biography, New York, 1829-30) being in 10 vols. This edition was republished at London in 2 vols. by Henry Rogers in 1834 and in 1860. See the *Life* by A. V. G. Allen (1839) and Squires's *Edwardean* (1903-4). —**JONATHAN EDWARDS**, second son of the preceding, was born in Northampton, Mass., 26th May 1745, and was educated at the College of New Jersey; he became tutor at Princeton, and in 1769 pastor at White Haven, Conn. Here he laboured with all his father's energy till dismissed by his congregation in 1795 on the plea of their inability to support a minister. Next year he was called to the church at Colebrook, Conn., and in 1799 to the president's chair of the new college at Schenectady, New York; but here he died 1st August 1801. He published an exposition of his father's theory of the will; and his own works, with *Life*, were published by his grandson in 2 vols. in 1842.

Edwin, king of Northumbria, was the son of Ælla, king of Deira, who died in 588. His father died when he was but three years old, whereupon Æthelric, king of Bernicia, seized his territories. The child was carried into North Wales, and there brought up. At length he found refuge with Rædwald, king of East Anglia, who took up arms on his behalf against Æthelfrith, the son of his oppressor, and defeated him in a great battle, in which the usurper fell (617). Edwin now obtained his father's kingdom of Deira, and ere long overran Bernicia, thus bringing under his rule a united Northumbria, which extended northward to Edinburgh, a city which he fortified, and which still retains his name. He next conquered Elmet (the West Riding of Yorkshire) from the Britons, and pushed his power westward to the sea, and even to Anglesea and Man. After Rædwald's death he also obtained the overlordship in East Anglia, and overthrew the West Saxons, a victory which gave him the overlordship of all England, save Kent. Edwin had already married Æthelburh, daughter of Æthelberht, the convert of Augustine. Under Paulinus' influence, and moved by his escape from assassination at the hands of the king of Wessex, and by his victory over Wessex, Edwin was converted to Christianity; and he and his nobles were baptised in the eleventh year of his reign. Thereafter, he became the most powerful prince in England. In 634 he fell in a disastrous battle at Hatfield Chase in Yorkshire. Edwin was canonised; his festival falls on 4th October. His story forms the subject of Alexander Smith's poem, *Edwin of Deira* (1861).

Eecloo, a town in the Belgian province of East Flanders, on the Liève, 12 miles NW. of Ghent by rail. It has manufactures of woollens, cottons, &c. Pop. 14,000.

Eel, a name somewhat widely applied in popular usage, but justifiably extended to all the members

of the family Anguillidæ, which is included in the order Physostomi of bony fishes. The family is a large one, with representatives in almost all fresh waters and seas of temperate and tropical zones. As is well known, the body is much elongated, cylindrical or ribbon-shaped; the usual scales are absent or rudimentary; and there are no pelvic fins. If unpaired fins are present, they unite in a long fringe. Teeth are usually well developed. Over two hundred species are known, all carnivorous, and preferring to keep near the bottom, sometimes at great depths.

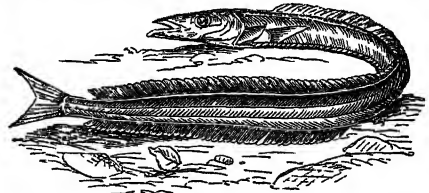

The genus *Anguilla* includes the eels *par excellence*, some twenty-five widely distributed species in all, the Common Eel (*A. vulgaris*) among the rest. The skin exhibits minute rudimentary scales, the upper jaw does not protrude, the tongue is free, the teeth small, the unpaired fins united in a continuous fringe. The common eel, though not without its mystery, is known to every one. The wide gape, the protruding lower jaw, the variable forms of head, the body cylindrical in front and then compressed, the long tail, the very varying colour, are familiar features. It occurs throughout most of Europe, frequenting, however, sluggish streams.

The Common Eel (*Anguilla vulgaris*).

Stealthy in its habits, the eel lies in the mud during the day, and wriggles about at night in search of all sorts of water-animals, including fishes. It is also certain that the eel may leave the water, especially when grass meadows are overflowed or wet with dew, and travel by night over the moist surface in search of food; its small external gill-aperture helps it to remain some time without water. In cold weather it hides itself in the mud. Eels never spawn in fresh water. The life-history, worked out by Schmidt, is remarkable. The mature eels pass from the rivers to mid-Atlantic, where they spawn, both sexes probably dying thereafter. The transparent larvæ (*Leptocephali*) live near the surface, and are for two years pelagic. After a remarkable metamorphosis they work their way to the shores, often travelling great distances. They migrate by day up the rivers, and are known as 'elvers.' Their marvellous procession is called the 'eel-fare.' The flesh of the eel is eaten, both fresh and preserved. They are caught by eel-spears, eel-pots, baskets, and in various other ways. (See FISHERIES.) In the blood of *Anguilla*, *Muraena*, and *Conger*, which is scantier than in most fishes, there is a powerful poison. The blood is exceedingly acrid to the taste, and though rapidly fatal when injected under the skin, is not markedly injurious in the stomach. The virulence of the poison is destroyed by heat.

The genus *Muraena* includes a large number of marine species, mostly well coloured, some of great length (6 feet), and with formidable biting powers. One widely distributed species (*M. helena*) was highly prized by the Romans, and is still fished. The genus *Conger* (q.v.) is separately discussed. *Muraenesox*, *Myrus*, and *Ophichthys* are other important genera within the family Muraenidæ.—The Electric Eel (*Gymnotus electricus*) belongs to a different though adjacent family (see ELECTRIC FISHES). The sand-eels (*Ammodytes*), which are

Sand-eel or Sand-launce (*Ammodytes lancea*).

often sought for bait, and are familiar to shore-wanderers, belong to quite a different set of bony fishes, and are also called *launce*. They are allied to the cods, and classified in the Anacanthini order. The marvellous adroitness with which they jerk themselves about in a pool, making use of the slightest cover of sand, is often admired.

A superstition has lingered through many centuries, finding typical expression in the works of Albertus Magnus, and repeated to-day in the experiments of country schoolboys, that horse-hairs left to soak in the brook grow into small eel-like animals. The fact at the root of this fancy is the frequent and sudden appearance of one of the Nematodes—the horse-hair worm.

The so-called 'eels' in paste, vinegar, fermenting and decaying substances, or stagnant water, are minute threadworms or Nematodes, often belonging to the genus *Anguillula*. Their bodies have the usual threadworm shape, and are almost transparent, though with thick cuticle. The rate of multiplication is very rapid; both eggs and adults have considerable power of reviving after Desiccation (q.v.). Adults have been known to reawaken after a maximum desiccation of fourteen years. See for these animals ASCARIS, THREADWORMS, &c.

Eel-pout, a name given in some parts of England to the Burbot (*Lota vulgaris*), and on some parts of the Scottish coast to the Viviparous Blenny (*Zoarces viviparus*).

Effen'di, a title of respect among the Turks, bestowed upon civil officials, and upon educated persons generally, in contradistinction to the military title of Aga. It is nearly equivalent to the French Monsieur, but is suffixed to the personal name.

Effervescence. Nearly all gases are more or less soluble in water, the amount of solubility depending on various conditions of pressure and temperature. As a rule, the lower the temperature and the greater the pressure, the greater is the solubility of a gas, so that when the temperature of such a solution is raised, or the pressure lowered, the gas escapes in small bubbles, giving rise to the phenomenon of effervescence. The most familiar instance of effervescence is when a bottle of soda-water is uncorked, the excess of carbonic acid gas over what can remain in solution escaping with effervescence. Again, when a seidlitz powder is mixed with water, effervescence occurs, owing to the inability of the water to retain the gas in solution. Many slight circumstances affect effervescence. Most people know that by stirring a glass of soda-

water, or by dropping into it a fragment of cork or a crumb of bread, greater effervescence occurs. Sometimes the liquid is rather viscid, and a persistent froth is produced, as when a siphon of lemonade is discharged into a tumbler. In such a case, the addition of a few drops of milk or of a little alcohol causes more rapid effervescence and settling of the froth. In the former of these cases, the bread crumb or the stirring acts by making it more easy for the gas to form bubbles and escape. In the latter case, the effect of milk may have a twofold cause, one similar to that of the crumb, the milk globules acting as nuclei; the other similar to the calming influence of oil on sea foam, the natural oil, butter, here coming into play. The alcohol merely acts by thinning the liquid.

Efflorescence, in Chemistry, is the term applied to the appearance of a white incrustation on the surface of certain bodies, as when a salt loses its water of crystallisation, and presents a white powdery appearance on the surface. Common washing-soda exposed to the air affords a good illustration of this phenomenon.

Eft (O.E. *efeta*, 'lizard'), synonymous with Newt (q.v.), a combination of the same root with the *n* of a prefixed *an* (*an-ef*, *an-ewt*).

Égalité. See ORLEANS (DUKE OF).

Egan, PIERCE (1772-1849), was the author of many works, including *Baxiana* and *Life in London*. The last, which Thackeray has immortalised in one of his *Roundabout Papers*, owed much to its coloured illustrations by the brothers Cruikshank.—His son, PIERCE EGAN the younger (1814-80), wrote innumerable novels for *Reynolds' Miscellany* chiefly and the *London Journal*.

Egba. See ABBEOKUTA.

Egbert, king of the West Saxons, was the son of Ealhmund, who bore rule in Kent, and was a descendant of the House of Cerdic. After the death of Cynegils (786), he was obliged by his more powerful rival, Beorhtric, to flee to the court of Charlemagne, whence he returned in 802 to fill the throne of Wessex. England was at this time divided into three great sovereignties: Northumbria, extending over what were occasionally the separate kingdoms of Deira and Bernicia; Mercia, which had now subjugated the petty powers of Kent, Essex, and East Anglia; and Wessex, which had absorbed Sussex. For his first twelve years Egbert reigned in peace; then followed a war with the West Welsh (Cornish), and a struggle with the Mercians, of which the turning-point was the great victory of Ellandune (probably near Winchester), and which ended in his being recognised as over-lord of their kingdom. In 829 the Northumbrians also, overawed by his army, accepted him as their suzerain, and thus Egbert became the first real king of England, although he did not formally assume that style, and continued to govern Mercia through its own king. Kent he bestowed upon his son Ethelwulf in 828, and did much to strengthen his own power by increasing the influence of the see of Canterbury. In his last years he had to struggle with a new and terrible enemy in the Scandinavian pirates, who began to harass the coasts. In 835 Egbert was defeated in a great battle in Dorsetshire, but in 837 he defeated, in a great battle at Hengestdune near the Tamar, a huge northern host allied with West Welsh insurgents. Egbert died in 839, having reigned thirty-seven years.

Egedé, HANS, the apostle of Greenland, was born in Norway in 1686, studied theology in Copenhagen, and was appointed pastor of Vagen in Norway in 1707. Having determined to convert the descendants of the Norse settlers in Greenland,

he resigned his cure in 1717, and four years later embarked with his wife, two sons, and some companions, in all forty-six persons. Finding the Norse extinct, he turned to the Eskimos. He remained fifteen years in Greenland, during which time he laboured zealously among the people, and by his preaching and teaching secured a permanent footing there for the Christian mission, which owed its origin to him. Latterly some Moravian missionaries invaded his province, with whom Egede failed to agree. The death of his devoted wife, Gertrude Rask, in 1736 drove him from Greenland, but at Copenhagen he was busy promoting the cause of the Greenland mission, of which in 1740 he became superintendent or bishop. He died 5th November 1758. He has described the course and success of his labours in *Det gamle Gronlands nye Perleustation* (Copenhagen, 1729 and 1741).—His son, POVEL EGEDE, born in Norway in 1708, succeeded his father in Greenland, and, as bishop, completed in 1766 the translation of the New Testament into the language of Greenland begun by his father, and prepared also a catechism (1756) and a prayer-book (1783) in the same tongue. He died at Copenhagen in 1789.

Eger, a town and river of Czechoslovakia.—(1) The town (Czech *Cheb*) stands on the right bank of the Eger, 50 miles NW. of Pilsen, and near the German frontier. It was formerly a border fortress, of some importance, but its fortifications were razed in 1809; it is now the chief railway centre in north-west Bohemia. The ruins of the imperial burg or citadel consist of a square black tower, a chapel (in the Romanesque and early Gothic style), and part of the great hall. The inhabitants of Eger (27,500 in 1921) carry on considerable trade and various industries, weaving, brewing, shoemaking, &c. In the town-house Wallenstein was murdered on 25th February 1634. Eger was taken by the Swedes in 1631 and 1647, and by the French in 1742.—(2) The river Eger rises 12 miles NW. of the town of Eger, in the Fichtelgebirge, at an altitude of 2362 feet, and flows in a general east-north-east direction, joining the Elbe opposite Leitmeritz, after a course of 190 miles. It is not navigable, owing to its falls and the boulders that obstruct its channel; but it abounds in fish. For another Eger, see ERLAU.

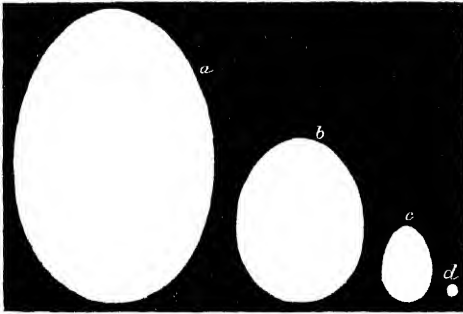

Egerdir, a small town of Asia Minor, gives name to a beautiful fresh-water lake, 30 miles in length, lying between the Sultan Dag and the northern offshoots of the Taurus Mountains.

Egeria, the Nymph or Camena from whom, according to the legend, King Numa received the ritual of public worship which he established in Rome. The grove where Numa met his mistress to receive her instructions was dedicated by him to the Camenæ. Roman legends speak of two groves dedicated to Egeria—one near Aricia, the other before the Porta Capena at Rome, where the grotto of Egeria is still shown.

Egg, the female cell from which the embryo is developed—a process which, except in Parthenogenesis (q.v.), normal or experimentally stimulated, begins only after fertilisation by the male sperm. Using the word as equivalent to ovum, we may talk with equal accuracy of the egg of any animal, whether sponge, butterfly, fish, bird, or elephant. The essential part of the ovum is generally minute, and the entire element often so remains, alike in the lowest and the highest animals; the presence of extrinsic material, however, often makes the egg large and conspicuous. The most important and frequent extrinsic addition is the yolk, which serves as nutritive capital for the embryo or young animal. Next in importance are the various sheaths which surround the egg, especially

when the outermost of these forms a chitinous, horny, or limy shell. Gristly fishes, reptiles, and birds afford very good examples both of abundant yolk and firm shells. We commonly associate eggs with (oviparous) animals which bring forth their young in that form, but this is a question of degree, for oviparous and viviparous forms often occur among nearly related animals; the common ringed snake, which usually lays eggs, may be artificially induced to bring forth its young alive, and even among mammals, where the connection between mother and offspring is characteristically intimate and prolonged, the two lowest genera (see *ORNITHORHYNCHUS* and *EGHIDNA*) are oviparous. For technical details in regard to the egg, the reader is referred to the articles *BIRD*, *CELL*, *EMBRYOLOGY*, and *REPRODUCTION*; attention will be directed here only to four points—size, shell, colouring, and economic interest, all with special reference to the eggs of birds.

Size of Egg.—The accompanying diagram shows the striking contrast in relative size between the

eggs of four birds,—the extinct moa, *a*, the ostrich, *b*, the hen, *c*, and a humming-bird, *d*. A moa's egg has been found measuring 9 inches in diameter, 12 in length, 27 in circumference. Ernst Krause mentions, in his most vivid of all general natural history books, that in the 17th century the inhabitants of Madagascar used to come to the *île de France* to buy rum, which they received in great vessels formed from the egg-shells of the extinct *Aepyornis*. These shells, some of which are to be seen in European museums, measure 3 feet in circumference, and hold over 2 gallons—i.e. some six times as much as an ostrich egg, or 150 times as much as a fowl's. In contrast to the above, the weight of the humming-bird's eggs is computed in grains. (Of European birds, the largest are those of the swan, the smallest those of the golden-crested wren.) It is not in birds alone that we find striking contrasts in the size of eggs; those of a skate contrasted with those of a salmon illustrate a striking difference. The difference in the size of eggs means a difference in the amount of yolk and other extrinsic substances present, but what conditions this difference is a difficult question. The size of the egg can only be said to be generally proportionate to the size of the bird, thus the cuckoo is much larger than the lark, but the eggs of the two are about the same size; the guillemot and the raven are of about equal size, their eggs vary as ten to one; and many other examples of disproportion might be given. Hewitson has noted that the eggs of birds whose young are rapidly hatched and soon leave the nest are large. Professor Newton remarks that 'the number of eggs to be covered at one time seems also to have some relation to their size.' It is probable that the size of the egg, which is familiarly subject to considerable variation in poultry, has been more or less fixed in adaptation

to different conditions in different types—e.g. the number to be covered in the nest.

The shell varies in composition in different classes. That of insects is chitinous (see *CHITIN*), of gristly fishes horny; a varying amount of lime is always present in reptile eggs, and predominates of course in birds. A bird's egg-shell consists almost wholly of carbonate of lime, but there is a little phosphate of lime and both salts of magnesia. Mr Irvine of Granton has made the interesting experiment of keeping fowls entirely without carbonate, allowing them only other salts of lime; the result was, however, that a normal carbonate of lime shell was still formed. The exact mode of formation of the limy shell is obscure; one can say little more than that the shell is secreted round the egg by the walls of the uterus or lower part of the female duct. In shape the egg is generally oval, but may be almost spherical, as in the kingfisher and owl; or pear-shaped, as in some of the auk family; or even doubly conical, as in the grebe. The pear-shaped egg of guillemots and razor-bills is well adapted to its precarious position on a ledge of cliff, for when it is jostled it rotates on its own axis without rolling. The same shape in the plovers allows close packing in the nest. In its surface texture the shell varies greatly, enamel-like in the kingfisher, oily in the ducks, pitted in some of the ostrich order, rough and encrusted in pelicans. Less conspicuous, but apparently to some extent characteristic of different families, is the minute structure of the shell.

Colour.—During the formation of the shell in the lower part of the oviduct of the bird pigment is also deposited. This occurs at various stages, producing the ground colour, the deeper, and the more superficial markings. The spots are normally circular, and most abundant on the anterior, larger, 'head' end, which first protrudes. As the egg is moved onwards, rubbing against the walls of the duct, the spots become in varying degrees blotched and diffused. The pigments themselves are numerous (Mr Sorby distinguishes seven), and seem mainly to be derivatives, directly or indirectly, of hæmoglobin, the red colouring matter of the blood. See *PIGMENT*.

The coloration varies in a single nest, and sometimes widely in a species. There is an extraordinary diversity of coloration in the eggs of guillemot, razor-bill, cuckoo, and the black-headed gull. Some evidence is forthcoming to show that a bird, such as a guillemot, which begins by laying an egg of a particular type of coloration, will continue to produce eggs of that type. This probably holds for the cuckoo, where the egg is sometimes very conspicuous in the foster-parents' clutch, and sometimes almost a facsimile except in texture. But it also appears that the quantity and quality of the pigments change with the constitution of the bird, the richest coloration being produced by birds at their prime. One of the most interesting facts in connection with the colouring of birds' eggs is their frequent similarity to their surroundings. Conspicuous eggs are usually in covered nests; and where the nests are rude and unconcealed, the eggs are very often like the colour of the ground. A valuable discussion of the colours of eggs will be found in Pycraft's *History of Birds* (1910).

Economic Import.—As the eggs of birds contain all the essentials for the nutrition of a young animal, they form, like milk, a highly nutritious diet for adult organisms. The contained albumen, fat, lecithin, and phosphates are all advantageous; and it need hardly be said that both man and animals are well aware of this fact (see *POULTRY*). The shells are occasionally turned to account—e.g. those of ostriches, for decorative purposes.—The enthusiasm for egg-collecting, shared by so many

naturalists, has probably not been equalled in any other department of natural science. Only a few quests, such as that for the eggs of the birds of paradise, have baffled the perseverance of collectors. The high prices paid for some treasures—e.g. the eggs of the great auk (£450 was paid for one in 1905) are only surpassed by those of some mollusc shells. This so-called sub-science of 'obology' has not, of course, been prosecuted without results of interest both in regard to the classification and general life of birds, but inquiry has largely passed from the collection and contemplation of egg-shells to the investigation of the embryo, and the deeper penetration has been richly rewarded. For some further particulars as to the egg-trade, imports of eggs into Britain, &c., see POULTRY.

Brewer, *North American Obology* (Washington, 1859); Cassell's *Book of Birds*; Hewitson, *Coloured Illustrations of the Eggs of British Birds* (3d. ed. Lond. 1856); Lucas, *Trans. Roy. Soc. Victoria*, xxiv. (1888); M'Aldowie, *Jour. Anat. Phys.* xx. (1886); Newton, article 'Birds,' *Encyclo. Brit.*; Sorby, *Proc. Zool. Soc.* (Lond. 1875); Carus Sterne (Ernst Krause), *Werden und Vergehen* (3d. ed. Berlin, 1886); Thienemann, *Fortpflanzungsgeschichte der gesammten Vogel* (Leip. 1845-56); Wolley, *Obtheica Wolleyana* (Lond. 1864). See articles *AUX*, *EIDER-DUCK*, *OSTRICH*, and *BIRD*.

Egg. See *EGG*.

Egga, an important trading town in the northern provinces of Nigeria, on the Niger, with a pop. of 15,000. Pottery, iron, gold, and wooden wares, thick cloth, generally dyed blue, and leather are manufactured.

Egg-bird, or *SOOTY TERN*. See *TERN*.

Egg-plant (*Solanum melongena*), a species of Solanaceæ, a native of Northern Africa, whose plant grows to a height of two feet; in Britain it is a greenhouse annual. The egg-like fruit, known as Egg-apple, Aubergine, amongst Anglo-Indians Brinjal, and in the United States Jews' Apple, is a favourite article of food in the East Indies, and has thence been introduced to most warm countries. It varies in size from that of a hen's egg to that of a swan's egg, or larger, in colour from white or yellow to violet.

Egham, a village of Surrey, on the right bank of the Thames, 5 miles SSE. of Windsor, and 18 W. of London. Near it are Runnymede (q.v.), Cooper's Hill (q.v.), and the Royal Holloway College for Women (1886). Virginia Water (q.v.) is also here. Pop. of urban district, 14,000.

Egidius. See *GILES*, ST.

Egina. See *ÆGINA*.

Eginhard, or *EINHARD* (c. 770-820), born at Maingau in East Franconia, was sent to the court of Charlemagne, where he became a pupil of Alcuin and a favourite of the emperor. Louis, successor of Charlemagne, continued his father's favour. For years Eginhard was lay abbot of various monasteries, but ultimately retired to Mülheim. Here he died, and was buried beside his wife, Emma. His *Vita Caroli Magni* (c. 820) is the great biographical work of the middle ages. It has been edited by Jaffé (1876), Holder (1882), and Garrod and Mowat (1915). There is an English translation by Glaister (1877). Eginhard's *Annales Francorum* embraces the period 741-829; his *Epistolæ* number sixty-two. See French edition of his works by Teulet, with translation and Life (1848). On the (purely legendary) story of his having made a romantic marriage with a daughter of Charlemagne, Fouqué founded his play of *Eginhard and Emma*, and Longfellow one of his *Tales of a Wayside Inn*.

Eglantine, the old and poetic name of the Sweet Briar or other smaller-flowered rose. Milton

seems to confound several quite distinct plants (honeysuckle, &c.) under this name; which has of late been bestowed on the Australian hardy evergreen *Rubus eglanteria*.

Eglinton and Winton, ARCHIBALD WILLIAM MONTGOMERIE, EARL OF, K.T. (1812-61), twice Lord-lieutenant of Ireland, was a well-known patron of the turf and field-sports, and is chiefly remembered for his splendid reproduction of a tournament at Eglinton Castle in 1839. Amongst the knights was Louis Napoleon. See Sir W. Fraser's *Memorials of the Montgomeries* (1859).

Egmont, LAMORAL, COUNT OF, PRINCE OF GAVRE, was born at the castle of La Hamaide, in Hainault, 18th November 1522. He accompanied Charles V. to Algiers in 1541 and in all his later campaigns, married the sister of the Elector Palatine in 1545, was invested with the Golden Fleece, and in 1554 went to England to negotiate the marriage between Philip and Mary. He distinguished himself at St Quentin (1557) and Gravelines (1558), for which he was made governor of Flanders and Artois. He now sided with the party in the Netherlands that were dissatisfied with Philip's Catholic policy, and from a courtier became a hero of the people. His imperious character, however, and his subsequent conduct, make it doubtful whether he was actuated by high motives or by self-interest and disappointed ambition. When Margaret, Duchess of Parma, was made regent, Egmont sided with the Prince of Orange; but when insurrections took place, he broke with the Prince of Orange and the 'Beggars' League.' He seemed to have restored order, when, in April 1567, the Duke of Alba was sent as lieutenant-general to the Netherlands. The Prince of Orange and other chiefs of the insurrection left the country; Egmont remained, and seemed to have gained his confidence, but suddenly he and Count Horn were seized and carried to Ghent. They were condemned to death, and on June 5, 1568, beheaded at Brussels. A famous monument to him was erected at Brussels in 1865; a more enduring memorial is Goethe's tragedy with Beethoven's music. See *HOLLAND*; Juste's *Le Comte d'Egmont* (1862); and Motley's *Dutch Republic*.

Egoism (Fr. *égoïsme*; Lat. *ego*, 'I'), an ethical term used in the sense of selfishness; it is specially opposed to Altruism (q.v., and see *ETHICS*). The word is sometimes used to denote a metaphysical system of subjective idealism, in which the Ego is the sole reality (see *FICHTE*).—*Egotism*, also derived from Lat. *ego*, is used rather in the sense of self-conceit, a tendency to refer constantly to one's self and quote one's own authority.

Egremont, a market-town of Cumberland, on the river Eden, 6 miles SE. of Whitehaven, whither it sends iron ore. On an eminence to the west stand the ruins of Egremont Castle, the legend of whose horn forms the subject of a poem by Wordsworth. Pop. 6600.

Egret. See *HERON*.

Eguren, JOSÉ MARÍA, Peruvian poet, born at Lima, has in his *Simbólicas* (1911) and other volumes of delicate symbolist verse reminded English readers of Walter de la Mare. He is also a painter and musician.

Egypt, a country in north-east Africa, extending from the Mediterranean to the first cataract of the Nile at Assuan, from 24° 6' to 31° 36' N. lat. The name is derived from the Greek *Aigýptos*, perhaps a translation of Hapaptah, 'the house of the ka of Ptah'—a name of Memphis—or formed from the Sanskrit root *gup*, 'to guard,' as *agupta*, 'guarded about,' or a variation of the name Koptos, the modern Quft in Upper Egypt, the city at which the dynastic Egyptians entered the Nile Valley.

In hieroglyphs and Coptic it is called *Kemi*, 'the black [land],' from the colour of the soil; and by the Hebrews, *Mazor*, 'guarded' or 'fortified' (in the singular—i.e. Lower Egypt), or *Mizram* (in the dual—i.e. Upper and Lower Egypt, but also used as a singular), modified by the Assyrians into *Musr*, and by the Persians into *Mudraya*. The name is still preserved in the Arabic *Misr* (vulgarly *Masr*), a word applied alike to the country and its capital, Cairo. Egypt is literally what Herodotus termed it, 'the gift of the Nile,' *doron tou potamou*, for it extends only so far as the annual inundation of the river spreads its layer of alluvial sediment, brought down from the washing of the Abyssinian mountains, turning the barren sands into cultivable soil, and then retreating to its normal limits, leaving the rich deposit to the influences of sun and air and human labour. Economically and ethnologically, Egypt is confined to the bed of the flooded Nile; the bordering deserts and the southern provinces of Nubia, Khartoum, and the rest towards the equator form no part of the Egypt of nature or of history, though from time to time they have been politically joined to it. Thus limited, Egypt occupies little more than 11,000 sq. m., or about a third the area of Ireland.

The White Nile rises in the Victoria Nyanza in Central Africa, the Blue Nile in the highlands of Abyssinia, the two streams meeting at Khartoum, and being joined 200 miles farther north by the only great tributary of the river, the Atbara. The whole course of the Nile, from the Ripon Falls, where the waters of the Victoria Nyanza find their outlet, to the sea at the Rosetta mouth, is 3473 miles. The river enters Egypt at Assuan, breaking through the transverse granite barrier which there runs east and west. The valley constituting the land of Egypt was formed by a fissure caused by upheavals on the east; the drainage of water falling into it widened it as a broad cañon through the plateau of limestone; the river thus formed has later cut its own bed in the deposits of gravel and alluvium with which it has itself overlaid the valley. The bed has varied its position in course of time, some of the old beds being still visible. In these ancient beds, worked flint implements are found among the rolled gravels. From Assuan to Edfu the cliffs which bound the Nile Valley are of sandstone; north of Edfu they are of limestone. The strata dip from south to north; the formations of the south are the earliest. South of Edfu the nummulitic limestone disappears completely, and is replaced by the so-called 'Nubian' sandstone. The eastern desert is entirely different in character from the western, being much higher, owing to the upheavals already mentioned. To the west the low ground only rises into cliffs at the south, and the plateau itself, the Libyan Desert, is level and rolling. On the east the cliffs begin at Cairo and the desert extends to the Red Sea, where the hills, formed of crystalline rocks, rise in peaks to a height of 6500 feet. The plateau of the eastern desert slopes down westward; it is formed of cretaceous and tertiary sandstones and limestones, and ends abruptly in cliffs which form the barrier on one side of the Nile Valley, and vary in height from 500 to 1400 feet. The eastern desert is subject to sudden and violent rainstorms; these when sufficiently near the valley cause rushing torrents to pour down the wadies, carrying all before them. Such rainstorms are more common than is usually supposed; they occur about once in two years. The chief physical peculiarity of Egypt is the fact that the whole agricultural water-supply depends on the Nile and its annual inundation, and not upon rain. The regular increase of the Nile every year is a phenomenon which has

excited the wonder of all writers on Egypt from the earliest times. This rise is due to the rainfall in Abyssinia, which causes the Blue Nile and the Atbara to come down in flood. In the dry season the Blue Nile is a small stream and the Atbara is reduced to a chain of pools; the White Nile, being fed from the great Victoria Nyanza, still retains sufficient volume to fill the river-bed. The current of the White Nile, when the river is at its lowest, is sluggish, and the slow current, combined with the hot sun, favours the growth of organisms in the water; these produce the phenomenon known as the 'green water,' which has a putrid taste and smell. The heavy rainfall of Abyssinia causes the Blue Nile to rise at the end of June; it brings down in suspension a heavy load of red soil washed from the mountains on which it rises. This is the 'red water,' which, flowing more rapidly than the green water, carries it quickly down to the sea. The Atbara also bears its part in the inundation, but not to so great an extent as the Blue Nile. The actual rise of the Nile is about 23 feet; the amount of water discharged by the river at Assuan is from 17,700 cubic feet per second at its lowest, to 323,000 cubic feet per second at the height of the flood. The waters of the inundation, spreading over the country on each side of the river, deposit their load of silt, the fertilising properties of which are due to the presence of phosphoric acid, potash, and nitrogen. The perennial irrigation now practised causes less soil to be deposited, the surplus being swept out to sea, where it is dispersed, forming wide shoals to the east.

The general appearance of the valley is thus described: 'In the centre the brown-toned river, turning reddish when swollen by the rains of the inundation; higher up on either side, but chiefly on the western, the bright green fields of waving corn, or beans, or lupin; then a border still higher of dusky barren rock; and then the slopes of the deserts—the long red and yellow and gray ridges of sand and limestone rock, generally low and tame in outline, and lying at some distance back from the river, but sometimes closing to the very bank in bold headlands, scored by torrent-beds where water rarely flows, and then shearing away to the distance of several miles, and leaving a wide, level plain of cultivable land' (Lane-Poole, *Egypt*). The Nile from Assuan to Cairo pursues a northerly course, varied by one considerable bend near Thebes. At 30° 15' N. lat., a few miles north of Cairo, it divides into two main streams, terminating in the Rosetta and Damietta mouths. The other five mouths which existed in antiquity have silted up; and the triangular or Δ-shaped district, enclosed by the streams and supposed by the ancients to have been recovered from the sea, forms the Delta. The southern part of the country from Assuan to Cairo is known as Upper Egypt; a part from Cairo to Darut esh Sherif is sometimes separated as Wustani or Middle Egypt, the ancient Heptanomis; and the northern part or Delta is Lower Egypt.

Though subject to cold winds in the winter, the climate is mild, especially south of the Delta and in the desert; from Cairo to Alexandria the air contains more moisture and is less salubrious; while the Mediterranean coast is subject to rain, and rendered less healthy by the belt of salt-marshes. The average temperature at Cairo ranges from 53° to 83° Fahrenheit, though it sometimes reaches 95° in the summer, or even 115° during the khamsin. At Assuan the average temperature is from 60° in the winter to 93° in the summer. The prevailing winds in Egypt are northerly from May to October, north-westerly for the remainder of the year, with the khamsin at irregular intervals in March, April, and May. The khamsin are hot

southerly winds blowing chiefly during the months of March and April. The simoom is a violent sand wind, commoner in the desert than in the valley, but rare anywhere. Earthquakes are occasionally felt. The Nile subsides within its banks by the end of November, and the irrigated land, over which the water has been carefully equalised by drains and embankments, is sown; soon it is covered with green crops, which are reaped in March. In spite of the dry air of the valley and desert, Egypt is by no means remarkably healthy; in addition to occasional visitations of plague and cholera, ophthalmia, diarrhoea, dysentery, and boils prevail, owing to the absence of rain favouring dirt habits and the high temperature favouring infection, and European and even Nigritic races are acclimatised with difficulty. With prudent modifications of our modes of life, however, British people, even young children, thrive well in most parts; and for certain classes of invalids—for instance, consumptives—the desert air is wonderfully recuperative.

Geology.—Egypt is separated from Nubia by a low, hilly region, about 50 miles broad from north to south, composed of granitic rocks. The same crystalline rocks extend up the shore of the Red Sea to near the opening of the Gulf of Suez, stretching inland for fully 30 miles. The scenery in this part of the Nile Valley is wild and rude, and the course of the river is frequently interrupted by cliffs and broken masses of granite, which form cataracts or rapids. The granitic region terminates at Assuan, the ancient Syene, whence the red granite for the ancient monuments of Egypt was procured. For about 85 miles, from Assuan to Esné, the walls of the valley are composed of sandstone of Cretaceous age; below Esné the sandstone is covered by a limestone belonging to the Upper Chalk series. This continues on both sides of the valley for about 130 miles, when it is covered by a Tertiary nummulite limestone, which forms the further prolongation northward of both ranges of hills. In the southern parts of the limestone region the magnificent cliffs and wild valleys form most striking scenery; frequent tablelands occur, on one of which are built the pyramids of Gizeh (q.v.), the material employed being the predominant limestone; while steep sand-dunes are met with in parts of the desert. Most of the area outside the valley is hard rock covered with scanty marl and gravels; in the flat lands bordering the Nile the rock is coated to a depth of about 30 feet (at the river's bank, thinning away towards the desert) with the alluvium brought down by its waters, which has formed the Delta at its mouth. This alluvium consists of an argillaceous earth or loam, with finely ground mica derived from the decomposed granite, and more or less mixed with sand, and a quartzose sand probably derived from the adjacent deserts by violent winds. This sedimentary deposit is so uniform that it seldom shows stratification, yet within short distances great variety is observed in what are apparently synchronous deposits. The increase of the deposit is estimated at about 4½ inches in a century.

The rocks of Egypt afforded the stones used in its edifices and sculptures: granite and syenite (from Assuan), basalt (from Abu Zabel), breccia (from the limestone caves), diorite, verde antique, and porphyry (from the mountains of the Arabian desert), sandstone and limestone (from the hills bordering the Nile), and alabaster (from Tell-el-Amarna). Emeralds, gold, silver, and copper were formerly found near the Red Sea; salt, natron, and sulphur are still among the mineral products. For the great Nile reservoir, see ASSUAN, NILE.

Natural History.—The signal peculiarity of the vegetation of the Nile Valley is the absence of

woods and forests. Even clumps of trees (except palms) are rare, though some have been recently planted. The Pharaohs obtained their timber chiefly from the Lebanon; perhaps in early times some was indigenous, as great wooden beams were used in the royal tombs of the 1st dynasty; modern Egypt is supplied from the forests of Asia Minor and Russia. The date and dōm palms, the sycamore, acacia, tamarisk, and lebbek are the commonest trees; the myrtle, elm, and cypress are rare; the mulberry belongs to Lower Egypt. Among fruit-trees, the vine, fig, pomegranate, orange, and lemon abound in special localities; apricots, peaches, and plums are of poor flavour; Indian figs (prickly pears) and bananas have been naturalised; and water-melons are at once the meat and drink of the people in the hot days. Of flowers, the celebrated lotus, or water-lily, supplied many ideas to Egyptian architects. Though common in ancient times, it is now seen only in neglected canals of the Delta, owing to the systematic drainage of marshes and swamps; for the same reason, the papyrus reed has also disappeared from Egypt.

The lack of jungle or cover of any sort accounts for the poverty of the Egyptian fauna. The hyæna, jackal, fox, hare, rabbit, jerboa, ichneumon, weasel, shrew, hedgehog, genet, polecat, spalax, and field rats and mice are common enough; the gazelle is the chief quarry; the wild-ass, wild-pig, and wild-cat are almost extinct; and the crocodile, like the hippopotamus, scared by European rifles and steamboats, has beaten a retreat to the tropics. The ordinary beasts of burden are the ass and the camel, the latter being always one-humped; the draught buffalo and the horse are importations unknown to the ancient Egyptians prior to the XVIIIth dynasty. The short-horned cattle, famous from the time of the Pharaohs, are seldom killed by the natives, and mutton is the staple butcher-meat in Egypt; goats also are common. The dog is considered unclean by Mohammedans, and is used merely as a scavenger and watch-dog. The cat is looked upon with considerable favour owing to its supposed enmity to snakes, which it is said to kill in large numbers. Bats are common in many of the ancient buildings and caverns. Of domestic birds, water-fowl were anciently the most numerous, and still abound; the small gallinaceous poultry we now see are probably not of older date than the Persian invasion. Pigeons have always been abundant. There are three or four varieties of vulture; eagles, falcons, hawks, kites, owls, hoopoes, swallows, wagtails, larks, sparrows, plover, and quail are common, and many of them figure in the hieroglyphics. An Ibis (q.v.), conjecturally identified with the sacred ibis of which many fables are told, is far from rare. The ostrich is now bred in farms in the Delta. Of reptiles, lizards, frogs, and toads abound, also chameleons. Snakes are numerous, both poisonous and non-poisonous; among the former are the horned snake Cerastes (q.v.) and the deadly cobra, the uræus or royal serpent of the ancient Egyptians. The trionyx, or soft tortoise, is plentiful in the Nile; the ordinary tortoise is found in the Delta only, but was known in prehistoric times. The Nile is full of fish, generally of rather poor flavour; the best are the biny (see BARBEL), the buly, the latus (one of the perch family), and the bayad or silurus. In the lakes of the Delta the dolphin is not uncommon. The Sacred Beetle (*Scarabæus sacer*) is one of the most remarkable insects. The scorpion's sting is sometimes fatal, and spiders (*solpuga*, erroneously called tarantulas by Europeans), to say nothing of minor insect pests, and locusts remind us that the Plagues of Egypt are not merely ancient history.

Egypt is essentially an agricultural country, and in some parts, by the aid of regulated artificial irrigation, the rich alluvial deposit will bear three crops in the year. Wheat is the chief cereal; but barley, maize, durra, beans, lentils, clover, &c. are also largely grown, with very little trouble beyond the management of the water. When fields require more fertilising material than the silt deposited by the Nile, the peasants dig the ancient sites, as the remains of the mud-brick buildings form an excellent fertiliser owing to the salts contained in them. The extensive culture of papyrus, which anciently supplied material for paper, has in modern times been superseded by that of the sugar-cane, cotton, indigo, and tobacco.

Divisions.—In ancient as in modern times Egypt was always divided into the Upper and the Lower, or the Southern and the Northern, country. A third great division, the *Heptanomis*, was introduced at the time of the geographer Ptolemy; it is now known as Middle Egypt or *Wustāni*. From the earliest period Egypt was further subdivided into a number of *nomes*, or departments, varying in different ages. The prehistoric division of the Delta was into eight nomes; these gradually increased, probably for political and administrative reasons, to thirty in the XIXth dynasty. In Upper Egypt the prehistoric nomes were four, increasing to thirty-six in the XIXth dynasty, and to fifty in Ptolemaic times. For religious purposes, however, the number seems to follow the divisions of the XIIth dynasty, twenty nomes for the Delta and twenty-two for Upper Egypt; forty-two in all. This number is emphasised by the forty-two assessors who sat with Osiris in the judgment of the soul, and who probably originally represented the principal god of each nome. Every nome, or department, had a separate local government of a nomarch or lieutenant-governor, besides governors of the cities and of the temples, scribes, judges, and other functionaries. Its limits were measured and defined by landmarks. In the 5th century A.D. Egypt was divided into Augusta Prima and Secunda on the east, and *Ægyptiaca* on the west, Arcadia (the Heptanomis), Thebais Proxima as far as Panopolis, and Thebais Supra to Philæ. Under the Mohammedans, the triple division into Misr el-Bahri (Lower Egypt), el-Wustāni (Middle), and es-Sa'īd (Upper) has prevailed, but the number of subdivisions has varied; at present there are fourteen provinces, or *mudiriyyehs*. Each province is governed by a *Mudir*, assisted by a council or *dawān*. The council is composed of the *Wakeel*, or deputy-governor; the *Kadi*, or judge; a chief clerk, tax-gatherer and accountant, a superintendent of police, and the chief physician of the province. Every province is subdivided into districts, each under a *Nazir*; under whom again are the *Sheikhs* of the villages. Certain towns—e.g. Alexandria, Cairo, Port Said—have their own government, and are not under the *Mudir* of the province. For the division of the territory beyond the limits of Egypt proper, see SUDAN (annexed 1876, abandoned 1885, reoccupied 1897-99).

Population.—The aboriginal people of Egypt appear to have been a dolichocephalic race, large-featured and tall, with intermixtures of Semitic and negroid elements. The Semitic stock appears to have been introduced early, as the language shows a marked affinity with other Semitic tongues. The overwhelming majority of the inhabitants are Moslems; the Copts (q.v.), though increasing, make up only 6.31 per cent. of the entire population. Of foreigners, the greater number are Bedouins and negroes; and there are, besides Armenians, Jews, Syrians, and Turks, Europeans of all nationalities (for details, see the section on Statistics of Modern Egypt). The Moslems belong to the sect

of Sunnis, with whom the grandsons of Mohammed—Hassan and Husên—rank as saints and martyrs. The Copts are Monophysites—i.e. believers in the one Nature of Christ; their ritual approximates to that of the Greek Church. The statements of Greek writers that castes existed in ancient Egypt appear to be founded on the fact that usually a son followed his father's profession; but, with one exception, every class might intermarry with any other class, and many men could follow two professions at once, as in the case of priests and soldiers. The only exception to the rule of free intermarriage was the class of hogherds, who were set apart as unclean, and were not only not allowed to marry outside their own 'caste,' but were not even admitted into the temples. Of caste as it is known in India there is no trace in either ancient or modern Egypt.

Religion.—The Egyptian religion began in primitive and savage cults, and ended as a philosophical pantheon. Each nome, or division, had its own deity, who was considered supreme in his own district. The earliest deities seem to have been goddesses, to each of whom were united later two male gods, looked upon as her husband and son respectively. These groups of deities, known as 'triads,' are found in all the principal centres of worship in Egypt, with the exception of Heliopolis. Thus Ptah, Sekhmet, and Imhotep formed the triad at Memphis; Amon-Ra, Mut, and Khons at Thebes; Hor-Beludti (Horus), Hathor, and Har-pakhrat (Harpocrates) at Apollinopolis Magna. Successive conquests and the advance of ideas caused the introduction of new gods, the older and more primitive deities being then grouped with the new one under the name of the *pesent*, or 'company of nine.' This was especially noticeable at Heliopolis, where the triad was not worshipped, Fig. 1.—Sekhmet. but where the three-times-three or ennead seems to have been first introduced. This Heliopolitan theory was transplanted to other centres of worship, but was never thoroughly established elsewhere.

In the XVIIIth dynasty an attempt was made, chiefly, it would appear, by the Heliopolitan priests, or by their influence, to introduce some uniformity into the confusion of the Egyptian pantheon. The great gods of the principal cities were identified with Ra, the sun-god, and thus we find compounds like Amon-Ra, Sebek-Ra, and Min-Ra. At the same time some of the goddesses were fused with Hathor and Isis; but as the worship of the female deity was older and more deeply rooted in the minds of the people, the fusion between the goddesses is not so complete as between the gods, and many of the goddesses retain a distinct and separate existence to the last.

The division into (1) Local Gods, (2) Solar Gods, (3) the Osiris cycle, makes the Egyptian pantheon intelligible. Under the Local Gods are comprised all the animal or animal-headed gods as well as the triads; the Solar Gods are the Heliopolitan ennead and all the gods whose worship is influenced by the Heliopolitan creed; in the Osirian cycle are the deities who surround Osiris. Each local god was considered in his own district as supreme over all other deities, and as the creator of gods and men; hence we have such varying legends as Khnum, the ram-headed god of Elephantine, forming men out of clay on the potter's wheel; Ptah

Fig. 1.—Sekhmet.

of Memphis creating the world out of matter or chaos; and from the tears of the god Khepera men and women came into being. When a principality rose into power through the local chieftain becoming king, the local deity became one of the great gods of Egypt, supreme for the time being, and ever after retaining a certain hold on the religion of the whole country, as Ptah of Memphis, who was the god of the kings who reigned at Memphis, and who composed the IVth, Vth, and VIth dynasties; Sebek, the crocodile, worshipped in the XIIth dynasty, the kings of which came from the crocodile-haunted province of the Fayûm; Amon, later called Amon-Ra, whose power rose with that of the Theban monarchs of the XVIIIth dynasty; Bast, the cat-goddess of Bubastis, whom the kings of the XXIInd dynasty specially worshipped.

The gods of the Solar cycle were identified by the Egyptian theologians with the cosmic deities familiar to all ancient religions. Ra was preceded as the sun-god at Heliopolis by Atmu (or Tum), but in historical times he has become the supreme deity, and the position of the older god is only indicated in some of the religious texts. The

rising sun was called Khepera or Horakhti (the Horizon-Horus), and was represented in the form of Harpocrates or Horus the Child; at the zenith he was named Ra; and Atmu was the setting sun. The Sun sailed in the Manzet boat on the celestial Nile above the earth; and as he sank in the west the souls of the dead, who accompanied him in his night journey, gathered at Abydos and passed through the Gap of Abydos into the Mesektet boat, in which the passage of the under-world was made. Here the corpse of the dead Sun, represented as a ram-headed figure, was towed by various deities and by the souls of the dead through the Duat, or other world, floating on the infernal stream as it had floated on the celestial river. This land of thick darkness, to which light came only during the passage of the Sun through its midst, was divided into countries, each division entered by a fortified gate. At each gate sat armed warders, while serpents belching flames protected the actual openings. At every hour of the night the boat with its sacred load, guarded and protected from all danger by the band of deities and souls, passed through one of the gates. At midnight the Sun was revived by the beetle—the scarab, the emblem of the resurrection—and alive and rejoicing he pursued his triumphant way, fighting and overcoming his eternal enemy, the snake Apep, and rising in glory over the earth as the child Horus in the morning.

The Osirian deities are those who cluster round the chief goddess and god of Egypt, Isis and Osiris. The legend of the enmity of Set against his brother Osiris; the murder of Osiris by Set; the flight of Isis to Buto; the search by Isis for the body of Osiris; her discovery of it at Byblus; Set's finding of it, and tearing of it into fragments to be scattered broadcast over Egypt; the second search of Isis, this time for the pieces of the body; her reuniting of them, and thus causing the revivification of Osiris; and the battles between Horus and Set, are fully related in Plutarch's *De Iside et Osiride*. Osiris, whose cult was spread throughout Egypt, was worshipped under four aspects—(1) as god of the moon, (2) as god of vegetation, (3) as god of the dead, (4) as incarnate in the king. In the ritual of this god, many survivals of primitive and savage customs were retained throughout the historical period. Isis, the myriad-named, had a cult quite distinct from that of Osiris, and figures of this goddess nursing the infant Horus are a prototype of the Madonna and Child. A few foreign deities were incorporated into the Egyptian pantheon when Syrian influence was at its height—Baal, Astarte, Anaitis, and Reseph being the best known. The so-called 'heresy' of Akhenaten at the end of the XVIIIth dynasty, worshipping only the rays of the sun and prohibiting all other devotion, is generally considered to have been due to Syrian influence. Many local deities were worshipped under the form of animals, in which they were supposed to be incarnate. The special animal so honoured was installed in the adytum of the temple, and gave oracular responses. The best known of these was the Apis bull of Memphis, whose worship had a national extension due to his being 'the incarnate soul of Osiris.'

The cult of the dead reached a very high point in Egypt owing to the belief in the *ka*, or double; offerings were made to it of food and of all objects necessary for its comfort, and as pictures were supposed to have *kas* which could be of use to the *ka* of the owner, representations of scenes of daily life were sculptured or painted on the walls of the tomb chapels. Herodotus is the only author who maintains that the Egyptians believed in the transmigration of souls; but in the Book of the Dead such transmigration or transformation is looked upon as a voluntary act, to be performed or not at the will of each individual. Besides the *ka*, there was also the *ba*, or soul, which went with the sun through the under-world.

Religious Monuments.—The religious edifices of the Egyptians consist of tombs and temples. These are indeed the chief survivals of their marvellous architecture, for their private houses (built almost entirely of sun-dried brick) are now mostly swallowed up in the rising alluvium, and but few forts remain. The Pyramids (q.v.) themselves are royal tombs, huge structures reared to mark and to guard the sarcophagi of kings, with small temples dedicated to the cult of the dead monarch in front. The royal tombs of the Ist and IIInd dynasties at Abydos, constructed of mud-brick and wood with but little stone, are the earliest Egyptian monuments. Then follow the pyramids, made at first of hewn stone and later of rubble and mud-brick, with smaller tombs, often finely sculptured, around them. The next are the rock tombs of the XIth and XIIth dynasties, in which the subterranean character of the pyramid-vaults is maintained in the deep well or burial-pit; the entrance-chapel, in which the memorial services were performed, is sometimes decorated, as at Beni Hasan, with a portico and proto-Doric columns, while the walls are adorned with paintings of scenes of daily life. At this period the chapel belonging to a royal tomb was placed on the edge of the cultivated

desert, in the axis of the tomb which was in the cliff behind. Finally, at Thebes the kings of the XVIIIth and succeeding dynasties built their magnificent funerary temples in the open space on the western desert, where their beauty could be seen by all, while the royal tombs were in the valley behind the cliffs, carefully hidden from human eyes. The finest of these rock-hewn sepulchres are those of Amenhetep II. and Sety I., which retain the rich and varied colouring still bright and fresh, showing the power and skill of the ancient artists. Egyptian temples can be divided into three classes—

(1) the royal funerary temple, (2) the processional temple, (3) the shrine temple. The royal funerary temples were for the cult of the dead king; they contain a statue of the king standing in an open court, and an altar for the offerings. The type of this kind of temple is the Ramesseum at Thebes. The processional temple is open front and back, and in the centre, under a roof, is a stone block on which the boat of the god was placed; the block was of a convenient height for the priests to raise the boat on their shoulders. The temple was open at both ends to allow the procession to pass in and out. The best example of this kind of temple is that of Thothmes III. at Medinet Habu. The shrine temple is found from the XVIIIth dynasty onwards, some temples which were originally processional being altered by later kings to suit the changed condition of the cult. The shrine is always enclosed and dark, sometimes built of masonry, sometimes made of a single block of stone. The figure of the god remained in the shrine, and was seen only by the priest of the highest rank and on rare occasions by the king. The shrine temple was looked upon as the dwelling-place of the god, in which the god was conceived to live as a king or nobleman lived in his palace—rising in the morning, his toilet performed by his servitors (the *hemu neter*, or 'servants of the god'), the incense being the morning and evening meals of the deity, and a bevy of priests and priestesses attending to his wants as the man-servants and maid-servants of a royal household attended on their human master. The typical shrine temples are Edfu (q.v.) and Denderh (q.v.). Karnak, the largest and perhaps the most celebrated temple in Egypt, is a mass of ruins. The obelisks which stood in front of the now completely destroyed temple of Heliopolis were removed by Cleopatra to Alexandria, whence one was brought to this country, and now stands on the Thames Embankment; while another has gone to New York—only one still remaining on the original site.

The ethical standard of the ancient Egyptians was a very high one. The so-called Negative Confession, recited by the dead man when his heart was being weighed in the balance before the great god Osiris, shows what deeds were considered sinful. Besides the sins of the Jewish decalogue, the oppression of the poor, the widow and the orphan, interference with the water-rights of others, falsifying weights, making mischief and stirring up strife, were included in the catalogue of crimes.

Ancient Civilisation.—According to the Egyptians themselves, the country was ruled first by the gods, then by ten semi-mythical kings, and lastly by the historical kings, of whom Menes was the first. This tradition is borne out by the discoveries at Naqada and elsewhere of a prehistoric civilisa-

tion, which lasted many centuries, though its exact duration cannot be fixed. The development of the great civilisation of Egypt can, however, be traced from its first beginnings in the early predynastic period, when the use of metal was hardly known and the potter's wheel had not yet been invented. In the 1st dynasty the working of stone for building purposes was already in use, the potter's wheel and the lathe had been introduced, as well as the notation of time, the Egyptian system of numeration, weights and measures, books on anatomy and medicine, the geographical division of the country, and

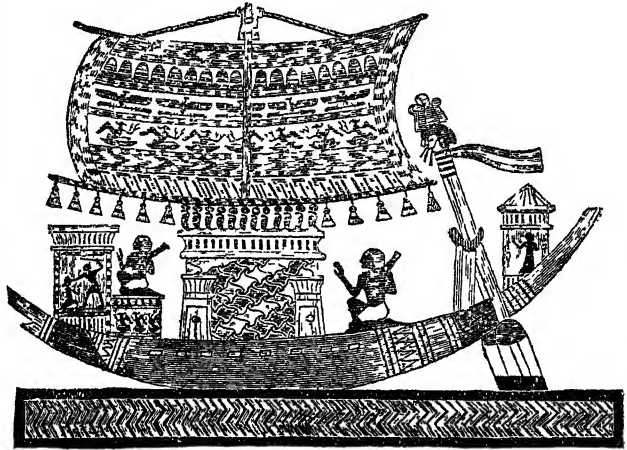

Fig. 5.—Sacred Bark.

the division of the year into 365 days, divided into three periods of four thirty-day months, with five intercalary days at the end of the year. By the IVth dynasty the buildings show a complete mastery of engineering and geometry; moreover, the arts could not have reached such a high development without some acquaintance with technical details of hardening metals and of glazing. The art of literary composition also existed at this early period, for two kings of the 1st dynasty are credited with being authors; long religious texts are found on the pyramids of the VIth dynasty, and a code of manners and morals drawn up in the Vth dynasty is still extant, though the actual papyrus is of the XIIth dynasty (see Papyrus; for Egyptian writing, see Hieroglyphics). Architecture had attained great refinement at an early period; not only were temples, tomb-chambers, and other edifices squared and directed to face the cardinal points, but cantilever roofs in stone were adopted as early as the IVth, and the brick vault or round-headed arch was in existence in the IIIrd dynasty. The transport of enormous blocks of stone testifies to an early development of engineering skill. Stone columns were in use in the IVth dynasty; in the Vth the palm column, the papyrus column, and the so-called proto-Doric column are first seen. The last is best known in the XIIth-dynasty tombs at Beni Hasan. The symmetrical arrangement of the temples, consisting of rectangular courtyards and hypæthral halls of many columns built before the original shrines, with their gateways slightly converging to the apex, and their bold and severe lines, prove the high development of architecture. The ashlar masonry of the pyramids is unsurpassed in the history of the world. Stone-sculpture reached its height in the IVth dynasty. The many conventions that bound the Egyptian artist show that stone-sculpture had its rise in clay-modelling. The support up the back of the figure, the foot advanced, the slab of

stone left between the legs, prove that the original material in which the artist worked was soft and yielding, requiring support lest the superincumbent weight should crush the lower part of the figure. When a firm and rigid material was introduced, conventions were so firmly fixed that no later artist could break free from them. The ivory statuettes of the 1st dynasty show a realism and a truth to nature that were never attained at later periods. The sculptures found at Meydûm, Gîzeh, and Saqqara—the celebrated figures of Rahoetep and

Fig. 6.—Ka-aper, the 'Sheikh el Beled.' was commoner in later times as a cheap substitute for sculpture; it had a rigid

architectural character, and followed the same canon as sculpture. The colours were laid on flat, the background being gray, white, or yellow. Outline drawings show a freedom of line and a mastery of form that is not surpassed in modern art. The architectural details of Egyptian temples and the hieroglyphs appear to have been always coloured, and this added additional charm to

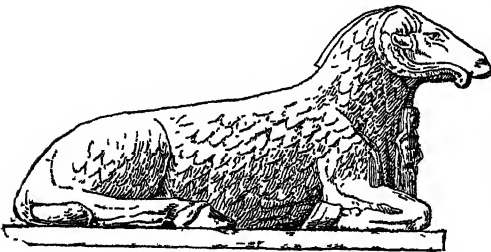

Fig. 7.—Ram-headed Sphinx.

the sculptures. The religious papyri were often embellished with elaborately coloured vignettes, somewhat resembling the illuminations of medieval manuscripts. The Egyptians were also much devoted to music, the harp and flute appearing in use as early as the IVth, and heptachord and pentachord lyres as early as the XIIth, dynasty; besides drums, tambourines, flutes, cymbals, trumpets, and guitars in the XVIIIth, the most primitive form was the jingling sistrum, the instrument used in all religious worship (fig. 9). Many of the instruments were of great size, and must have produced considerable effect. Songs were chanted to the accompaniment of various instruments, and women

beat time to their chants by clapping their hands to emphasise the rhythm. The well-known threshers' song, which occurs in the tomb of Ty of the VIIth dynasty, has been paraphrased as :

He along, oxen,
Thresh the corn faster,
The straw for yourselves,
And the corn for your master.

The refrain to this song was, 'Thresh for yourselves, O oxen.' The peasant songs were, in all probability, like the peasant songs of modern Egypt—a line of solo, with a refrain in chorus. In more ambitious poetry the same method is preserved in the strophe and antistrophe, of which the earliest and finest example is the Hymn to Senusert III. of the XIIth dynasty. In the mechanical arts many inventions had been made. The blowpipe, used on a large scale for metallurgy, appears in the VIIth dynasty (fig. 10); bellows and siphons in the XVIIIth. Copper adzes, chisels, and harpoons were employed in the prehistoric periods; the use of the lever was fully understood in the IVth dynasty; the balance appears very early, but the steelyard does not occur till Roman times. Flint was the common material for tools in the prehistoric period, though the use of metal was already well known. At first copper was the chief metal; this was superseded by bronze in the XVIIIth dynasty, and iron, though known at all periods, is not common till the XXVIth. The earliest dated Glass (q.v.) made in Egypt is of the reign of Thothmes III.; but glass, evidently imported, is known as early as the 1st dynasty. Hand-made pottery was used in the earliest prehistoric period, and a glazed ware and wheel-made pottery begin in the 1st dynasty. The Egyptians used, at an early period, shields and cuirasses of quilted leather; their weapons were stone-headed maces, clubs, bows, and daggers in prehistoric times, while spears and swords appear later. For sieges they employed the testudo, ladders, and mines. The army was composed of infantry till the XVIIIth dynasty, when war-chariots were introduced; for prior to that period the ass was the chief means of transport, and, carriages not having been invented, persons and goods were carried on the panniers of asses, or on a kind of saddle slung between two animals. War-boats no doubt existed at an early period; models and paintings of boats occur in prehistoric times, and mention is made of ship-building under the IIIrd dynasty, and of an armed expedition by boat to Nubia in the VIIth dynasty; a regular navy occurs in the IIIrd, when Snefru built a fleet of sixty ships. The Nile, however, being the chief highway of Egypt, was constantly navigated by rowing and sailing vessels. An extensive commerce was carried on with neighbouring nations, and their tribute enriched the country with slaves, cattle, gems, valuable metals, and objects of curiosity. Rare animals were collected for ostentation. Under the earlier dynasties, the chief occupation of the nation appears to have been rearing cattle and cultivating grain, while the amusements consisted of banquets, games, hunting, and fishing; and the establishment of each noble—like that of a feudal baron of the Middle Ages—contained in itself all the organisation and artificers necessary for its maintenance. Transactions were carried on largely by barter; though rings of gold, probably of a standard weight and value, were also used. The unit of value, however, was always reckoned in copper. The Persians first introduced coined money (see NUMISMATICS). The wealth of families was often spent on the tombs and furniture of the dead, and the preparations for embalming were on so vast a scale that filial piety did not disdain to mortgage not only the sepulchres, but the very mummies of its ancestors (see EMBALMING).

Amusements were various, from singlestick and juggling, the dance of the *ghawazi* (fig. 11), and bull-fights, to draughts, dice, and *mora*. In fact,

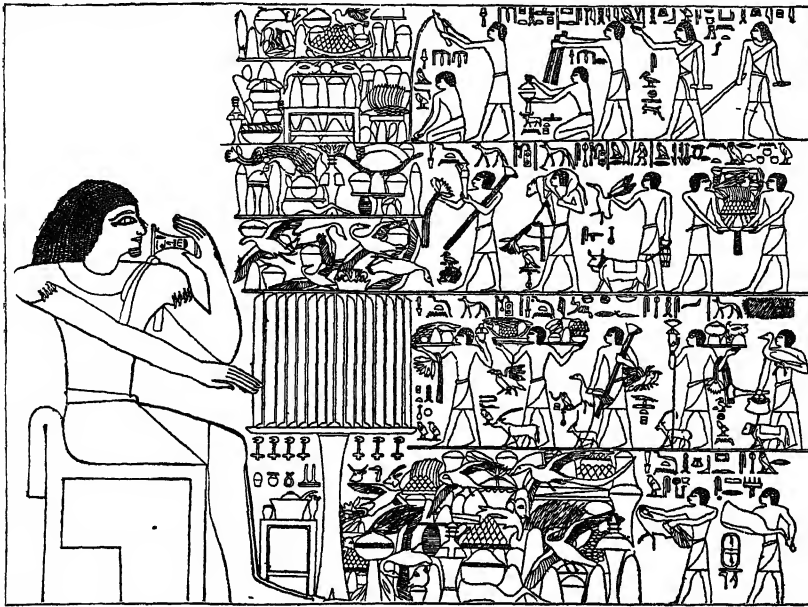

Fig. 8.—Wall-painting from the Tomb of Ptah-hotep, at Saqqara: of the Pyramid age.

ancient Egypt had, like any modern country, a material civilisation, which exerted all the requirements of industry, and forgot none of idleness.

The civil government was administered nominally by the Pharaoh, whose substitute was the vizier. Each province had its own governor, who was responsible for its good administration; the mechanism of government was carried on by officials of various kinds and grades. Sacred scribes attended to the ecclesiastical interests, and inferior scribes to the local interests. The public works, the collection of grain and other dues, the cattle, workmen, wells, irrigation, had each their separate organisation of superintendents and scribes. The temples were ordered by high-priests and an inferior hierarchy, with overseers and governors of revenues, domains, and donatives; and each temple, like a monastic institution, had its carefully subdivided organisation. The military force was ruled with severe discipline, under the direction of nomarchs, colonels, captains, and lieutenants. In early times there was a local militia, aided by foreign mercenary troops; this gradually developed into a standing army, and in the reign of Rameses II. we

Fig. 9.—Sistrum.

find the army divided into territorial divisions. The criminal and civil law was administered by judges, who held travelling assizes, and to whose tribunals the necessary officers were attached. Appeals could be made to the Pharaoh, to the vizier, and, in Roman times, to the prefect. The execution of deeds required so many witnesses that fraud evidently often occurred. The superior position of women in the social scale, notwithstanding the permission to marry within degrees of consanguinity usually forbidden, shows that the Egyptians reached a higher point of delicacy and refinement than either their

eastern or their western successors. This high position was due to the fact that all landed property, including the throne itself, descended in the female

line, from mother to daughter. Colossal in its art, profound in its philosophy and religion, and in possession of the knowledge of the arts and sciences, Egypt exhibits the astonishing phenomenon of an elevated civilisation at a period when the other nations of the world were almost unborn.

Chronology and History.—In the time of Ptolemy Philadelphus, in the 3d century B.C., Manetho of Sebennytus, high-priest of Heliopolis, who had the best records of his country at his command, drew up, at the request of the king, a history in which we have the complete statement of the old Egyptian division of the space of time, from Menes

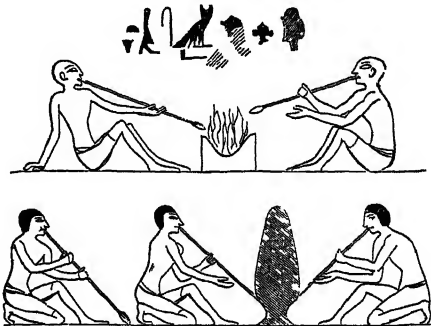

Fig. 10.—Egyptian Smith.

to Alexander the Great, into thirty dynasties. The original work of Manetho has perished; but chrono-

Fig. 11.—Musicians and Dancers.

logical epitomes have been preserved by Julius Africanus (300 A.D.), Eusebius, and Georgius Syn-

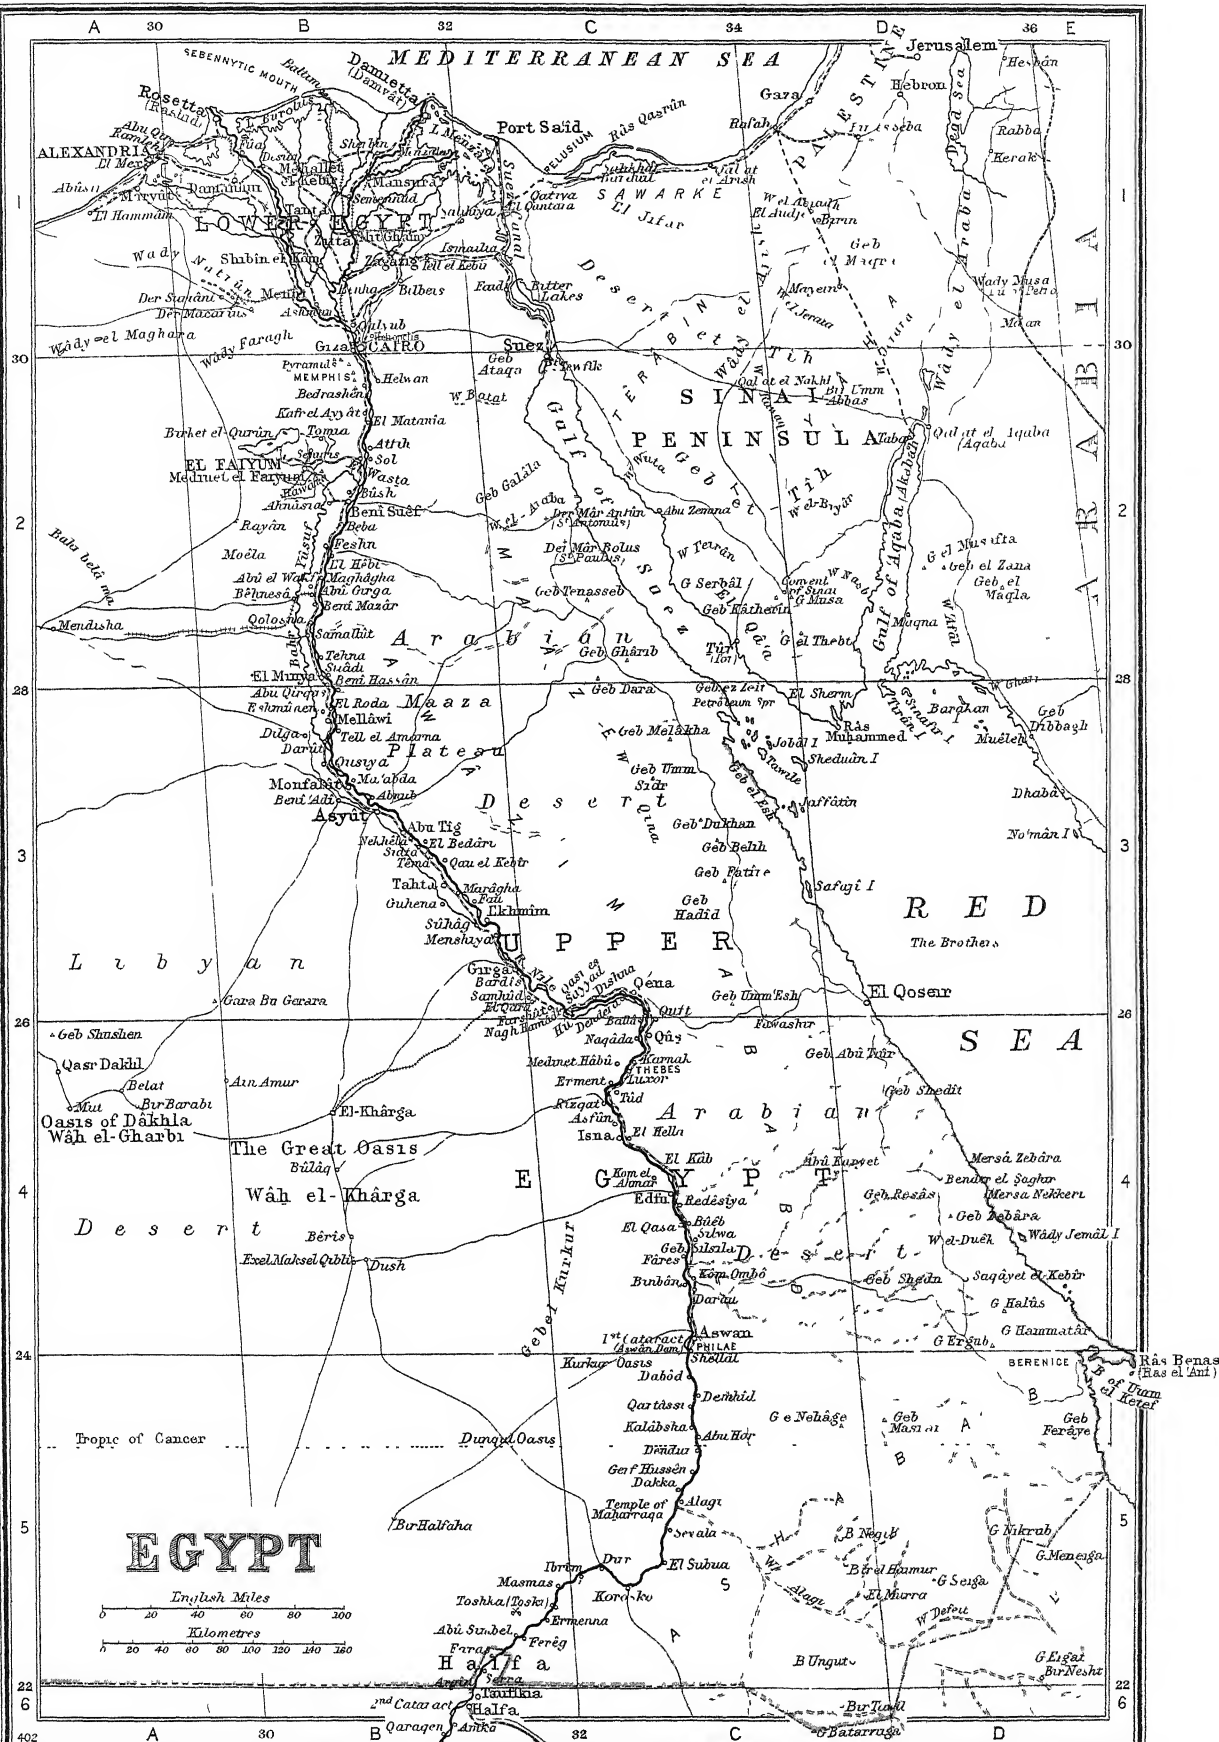

cellus (800 A.D.), and a comparison of these statements, corrupted as they are, with the records of the monuments has clearly established the truth and authenticity of Manetho's authorities. The Hebrew Scriptures, Herodotus, Diodorus, Josephus, Eratosthenes, and others also contain chronological information. The division of the kings into dynasties is followed by all modern Egyptologists—the actual date of a dynasty being arrived at, where possible, by astronomical or seasonal data. The Egyptians themselves had a double calendar—(1) the official calendar, which consisted of 365 days in the year, losing a day every four years, and therefore shifting gradually through all the seasons; and (2) the solar calendar of 365½ days in the year. The two calendars coincided once in every 1460 years, this period being called by the Greeks a Sothic cycle, from Sopd, Sothis, or Sirius, the Dog-star; for the Egyptians calculated their new year from the rising of the Dog-star at dawn.

As the chronology is still a matter of dispute, the table of dynasties which follows gives the dates from the 1st to the XVIIIth dynasty as calculated from Manetho's History, and the same dates as calculated by Meyer. After the XVIIIth dynasty, the two methods being practically in agreement, only one date is given for each dynasty.

Dynasty	Manetho.	Meyer.

Egypt was fabled to have been first governed by a dynasty of gods, who, according to Manetho and other authors, were: Hephæstus (Ptah), Helios (Ra), Agathodæmon, Kronos (Geb), Osiris, Typhon (Set), and Horus. These gods reigned 13,900 years, and were succeeded by the demi-gods, manes, and mythical kings, who reigned 11,000 years in all. This fable points to a tradition of an ancient and settled government of long duration, in which the power was wielded by kings of North and South Egypt before the date of Menes, the first historic king; a tradition which has been confirmed by the discovery of prehistoric burials, showing a long period of rising and waning civilisations before the advent of the dynastic Egyptians. The epoch of Menes is the starting-point of Egyptian history, and is placed at 5500 B.C. by Manetho, at 3400 B.C. by Meyer. Menes has been identified with King Narmer, of whom several contemporary monuments still exist. He is said to have founded Memphis by diverting the course of the Nile, to have made laws and instituted the worship of the gods, and, finally, to have been killed by a hippopotamus.

His immediate successor, Atothis, is traditionally credited with the authorship of a treatise on anatomy. The tombs of the kings of the 1st dynasty are at Abydos, and were excavated first by Amélineau and then by Petrie. The objects found there include pottery, vases of hard stone, copper implements, carved wood and ivory, some very fine weaving, and jewelled bracelets, which are among the finest examples in the world of the goldsmith's art. The first recorded expedition to Sinai to obtain copper occurred in the reign of Semerkhet (Merskha) of the 1st dynasty. In the 11th dynasty the primitive worship of sacred animals was reintroduced, and the right of inheritance through the female line officially sanctioned. Zeser, the king of the 11th dynasty, was the builder of the Step-pyramid of Saqqara, the first of the Egyptian pyramids; and the last king of this dynasty, Snefru, built the pyramid of Mejdâm. Round his pyramid were buried the nobles and officials of his court; and in these tombs were found inscriptions and sculptures, among them the famous seated figures of Rahetep and his wife Nefert. The first three dynasties lasted 769 years, the 14th dynasty beginning about 4700 B.C. Khufu, the Cheops of Herodotus, constructed the Great Pyramid at Gîzeh, and has been handed down to posterity as an impious and cruel tyrant by the priests whom he offended; for he closed the temples and forbade sacrifices, thereby relieving the people from a heavy burden and striking a severe blow at the power of the priesthood. Khafra (Chephren), his successor, built the second of the Gîzeh pyramids and continued the policy of Khufu. Menkaura (Mycerinus), who built the third pyramid, reversed that policy, reopened the temples, and restored the priesthood to power. The high civilisation of this period marks an epoch in Egyptian history, and the numerous tombs of this and the subsequent dynasty exhibit a highly advanced state of art. The statues of Khafra (found near the Sphinx), carved in black diorite, are notable evidence of artistic feeling and mechanical skill; the cultivation of farms, the chase, the arts, enjoyed a great part of the attention of the Egyptians; the simpler mechanical inventions were in common use, but the horse and chariot had not yet been introduced. The 5th dynasty was also Memphite, and consisted of nine kings, reigning about 220 years. The 14th dynasty, also from Memphis, lasted about 200 years. Tombs and inscriptions of this period are found throughout Egypt—from Assuan to Tanis, and even in the Wady Hammamât, the valley leading from Koptos to the Red Sea. The pyramids of these kings are at Saqqara, and are remarkable for the inscriptions on the walls of the tomb chambers. These inscriptions are now known by the name of the 'Pyramid-texts,' and are the earliest religious writings that have yet been discovered in Egypt. They throw great light on the early beliefs of the country, and elucidate some of the chapters in the Book of the Dead (q.v.), or Ritual, of later times. They are also of great importance linguistically, being the only long texts in the archaic form of the language which remain to us. Pepy II., the fifth king of the 14th dynasty, is recorded to have reigned ninety-five years, coming to the throne at the age of five and dying at the age of one hundred. During his reign armed expeditions were sent into Nubia under a captain named Una, in whose biographical inscriptions many historical details are preserved. The dynasty ended, according to Manetho, with a queen (Nitocris), said to have been buried in the Third Pyramid of Gîzeh. Nitocris is the subject of various legends, and is believed by the Arabs to be a witch who still haunts the pyramid. The period from the

beginning of the IVth to the end of the Vth dynasty is known as the 'Old Kingdom.'

From the Vth dynasty to the XIth Egyptian history is almost a blank, and the remains scanty and fragmentary (Petrie, *Sedment*). In the XIth dynasty, however, the country became more settled under a line of kings called Antef and Mentuhotep, whose coffins and burial-places have been discovered at Thebes. A decree deposing one monarch and appointing another is dated to the reign of Antef V, and was found at Koptos. The successive reigns and monarchs of the XIIth dynasty (B.C. 3579) are fixed by numerous monuments. Amenemhat I., the founder of the line, opened the quarries of Tura, and embellished On or Heliopolis. The monuments of his successor, Senusert I., exist in many parts of Egypt, notably in the Fayûm, Beni Hasan, Heliopolis, and Koptos. His campaigns gave Egypt peace on her borders, thereby allowing the country to develop its resources. Senusert III.'s campaigns carried the frontier of Egypt as far south as Semneh; he was worshipped as a god in Nubia until the middle of the XVIIIth dynasty or later. Amenemhat III. was the first to control the inundation of the Nile, by forming Lake Mœris as a vast reservoir for the surplus water; he also built the Labyrinth, which roused the wonder and admiration of later ages, and constructed the pyramid beside it. The period from the XIth dynasty to the XIIth is known as the Middle Kingdom. It is from this period that we obtain some of the finest specimens of Egyptian literature; the stories of the Westcar Papyrus are not only folk-tales, but autobiography (the Story of Sa-nehat) and attempts at literary composition (the Eloquent Peasant). The great Hymn to Senusert III., found at Kahun, is composed in strophe and antistrophe.

Another blank period occurs between the XIIth and the middle of the XVIIth dynasty. At the beginning of this time a great movement took place of the peoples in the north and east of Syria; they seem to have moved southward, conquering as they went, and finally appeared in the Nile Valley, where they were known to the later Egyptians as the Hyksos, or Shepherd Kings. These invaders took possession of Lower Egypt and Memphis, and established a great stronghold at Avaris, the modern Tell-el-Yehudiyeh, at the entrance to the Wady Tumilat (see Petrie, *Hyksos and Israelite Cities*). Joseph was perhaps the viceroy of one of the later Hyksos kings. Seqenen-Ra, the last king of the XVIIth dynasty, lost his life in a battle against the Hyksos in Upper Egypt; but the work of expulsion was carried on by Aahmes I., his successor, the first king of the XVIIIth dynasty (about 1600 B.C.), who took Avaris by assault, and drove them into Syria, where their power was completely broken in the campaigns of Amenhotep I., the immediate successor of Aahmes I. Thothmes I. continued the career of conquest begun by his predecessors, making expeditions into the heart of Nubia in the south, and as far as the Euphrates in the north. He also began the magnificent buildings for which the XVIIIth dynasty is so justly famous. Thothmes II. is best known as the husband of the greatest of all Egyptian queens, Hatshepsut. She was associated by her father in the government with himself, and after his death and the death of her husband she ruled alone, as her son-in-law and successor, Thothmes III., was not old enough to take up the reins of government. Under Thothmes III. and his immediate successors Egypt reached the highest point of material prosperity to which she ever attained. The conquests of Thothmes III. made Egypt mistress of the greater part of the known world, with an extended sphere of influence in the Ægean. The whole of Syria

was subject to Egypt, the vassal-kings paying a yearly tribute to the Pharaoh as their overlord. Nubia, as far as the third cataract, also owned the dominion of Egypt; and trade with these foreign countries increased the wealth and prosperity of the country. The temples of the gods were endowed with large revenues from the tribute of the conquered nations, and the temple of Amon at Karnak increased in size and elaboration. A calendar preserved at Elephantine records the heliacal rising of the Dog-star on the 28th of Epiphi; the actual date has been calculated by Mahler by means of the recorded dates of two new moons occurring in this reign, and is thus proved to be the year 1470 B.C., a date within ten years of that obtained by adding together the lengths of reigns as given by Manetho. The reign of Amenhotep III. is the culminating point in the glory of the XVIIIth dynasty. His monuments are found throughout Egypt; the best known are the temple of Luxor and the two Colossi of Thebes, one of which is the celebrated Vocal Memnon of the Greeks. In this reign can be discerned the beginning of a heresy, apparently fostered by Queen Tyi, which became the dominant factor in the following reign. Amenhotep IV. succeeded his father, Amenhotep III. A fanatic and an enthusiast, he sacrificed everything in his zeal for the new religion. He changed his name to Akhenaten (Glory of the Sun-disk); he mutilated monuments on which the name of Amon occurred; he removed the capital from Thebes to Akhet-aten (the modern Tell-el-Amarna); and in his attempts to destroy the ancient and national faith, he neglected his foreign dominions, reducing his own country to anarchy, and losing the provinces of Syria, that great possession left to him as an inheritance from his fighting ancestors. The cult of the Aten, for which Akhenaten strove with fanatical zeal and energy, lasted but a few years after the death of its royal votary. Tutankhamen, his immediate successor, returned to the old faith, and was buried among the Amon-worshipping kings at Thebes. His tomb was found by Mr Carter and Lord Carnarvon in 1922, and is the only untouched royal burial yet discovered.

The link which connects the monarchs of the XVIIIth with those of the XIXth dynasty has been lost, but we know that the first king of the XIXth dynasty was called Rameses, a name that was borne by eleven of his descendants in the XIXth and XXth dynasties. He was succeeded by his son Sety I., who made a gallant and partially successful attempt to recover the lost country of Syria; but though he held southern Syria as far as Galilee, the northern provinces never again submitted to Egypt, and his campaigns were mere raids which produced no lasting effect. He undertook the pious duty of restoring the monuments mutilated or destroyed in the troubles at the end of the previous dynasty, and the temple which he built at Abydos is one of the finest examples of the technical skill of Egyptian artists. His tomb, in the Valley of the Tombs of the Kings at Thebes, was discovered by Belzoni. The rock-hewn passages and chambers are covered with scenes and inscriptions of the nightly journey of the Sun through the under-world. On the death of Sety I., his son Rameses II. ascended the throne; the date calculated from the horoscope of the latter is 1300 B.C. His reign lasted sixty-six years. He fought several campaigns in Syria at the beginning of his reign, and penetrated as far north as Naharaina, but he never held the country, and finally was obliged to retire after making a treaty with the Hittite king. This treaty was engraved on a tablet of silver, a copy of which was sculptured on the walls of Karnak; the Hittite copy, written in cuneiform

on a clay tablet, has been unearthed at Boghaz Keui. It is an extradition treaty, and the articles show that the Hittites (q.v.) were strong enough to treat with the king of Egypt upon equal terms. The battle of Kadesh is the most famous of the exploits of Rameses II.; it was celebrated in an epic by the poet Pentaur, and the poem with scenes of the battle was sculptured on the walls of many temples. Rameses II. was a great builder, and remains of his work are found on every important site in Egypt. His most splendid monument is the rock-hewn temple of Abu Simbel, at the entrance to which are the largest colossi in the world. The storehouses in the city of Pithom (Tell-el-Maskhuta) are dated to this reign. The long and increasingly feeble reign of Rameses II. proved disastrous to Egypt. Her power rapidly declined; and so far from holding foreign dominions, foreigners invaded the Delta, settling there and ousting the inhabitants. Art also declined rapidly, and became coarse in technique and completely wanting in vitality. Merenptah, the thirteenth son of Rameses II., succeeded to the throne; but though advanced in years, he began his reign with vigour, driving out the foreign settlers and restoring order in the Delta. In the Triumph Stela of Merenptah is the only mention of the people of Israel that has yet been found in Egypt. The later kings of the XIXth dynasty were of no importance. The XXth dynasty opens with Rameses III., whose naval victories and wars with the Syrian and African races are recorded on the walls of his temple at Medinet Habu. The list of his benefactions to the temples of Egypt is recorded in the Great Harris Papyrus, and the legal account of the trial of the ringleaders of a harem conspiracy, by which Rameses III. appears to have lost his life, is one of the most interesting documents that remain to us. The rest of the dynasty consists of the sons and grandsons of Rameses III., who gradually fell under the power of the priesthood of Amon. On the death of the last Rameside, the high priest of Amon, Herhor, became king, and founded the XXIst dynasty. A rival government was established at Tanis in the Delta. The daughter of the last Pharaoh of this dynasty was married to King Solomon. The XXIInd dynasty is more important chronologically than historically, for Sheshanq I., the first king, is the Shishak of the Bible, who invaded Syria and raided Jerusalem in the reign of Rehoboam. The sculptures of Osorkon II., found by Dr Naville while working for the Egypt Exploration Fund at Bubastis, are important for the study of certain aspects of Egyptian religion. In the XXIIIrd dynasty, Piankhy, king of Ethiopia, invaded and conquered Egypt, establishing his own family on the throne. The XXIVth dynasty consists of one king only, Bak-en-renf, the Bocchoris of Manetho, who is said to have been taken prisoner and burned alive by the Ethiopian Sabaco of the XXVth dynasty. From this period Egyptian history is connected with the histories of Judaea and Greece. Tirhakah, who came to the assistance of Hezekiah against Sennacherib, ruled over Egypt and Ethiopia. He was driven out of Egypt when that country was invaded and conquered by the Assyrians under Ashur-bani-pal. The Assyrians divided the country into provinces, each under its own governor, but at the beginning of the XXVIth dynasty (650 B.C.) Psammetichus, by the help of Greek mercenaries, united the country under one strong central government. During this dynasty the Greeks first settled in Egypt; Naukratis was granted to them as a trading port, while the mercenaries were settled in different parts of the country; the camps of the mercenaries eventually became trading centres until the Egyptians grew jealous, and Amasis II. suppressed them, at the

same time granting special privileges to Naukratis, which was permitted to remain. A canal across the Isthmus of Suez was planned and begun by Necho, in whose reign Phoenician sailors first sailed round the Cape of Good Hope. Necho invaded Syria and defeated Josiah, king of Judah, but was himself defeated and driven back by Nebuchadnezzar at Carchemish. Apries (the Pharaoh Hophra of Jeremiah), after reigning a few years, became involved in civil war, and was defeated by his rival, Amasis II.; after being kept a prisoner for three years, he was put to death. The character of Amasis left a lasting mark upon the minds of his subjects, and Herodotus records many anecdotes regarding him. In this dynasty there was a renaissance of art, and archaic forms of language and customs were revived. The style of sculpture is archaistic, the statues of the Old Kingdom serving as models. At the death of Amasis, Cambyses invaded Egypt, and from the XXVIIIth to the XXIXth dynasty Egypt was in the hands of the Persians, though a few native kings struggled feebly to maintain the independence of the country. The XXXth dynasty was successful in this endeavour, and drove out the Persians for a short time. The chief kings of this dynasty were Nectanebo I. and Nectanebo II. The last-named was traditionally credited with being a great magician. The Persians again invaded and took possession of Egypt, but so great was their misrule that Alexander was hailed by the Egyptians as their saviour when he defeated the Persians and drove them out of the country.

Egypt now passed under the influence of Greece; for on the death of Alexander the Great one of his generals, Ptolemy, made himself king of Egypt and founded the Ptolemaic dynasty. The earlier Ptolemies were enlightened patrons of learning. The foundation of the Museum and Library of Alexandria, and the liberality displayed by the kings, attracted all that was best in literature, science, and learning to Egypt. The Septuagint translation of the Hebrew Scriptures, the history of Manetho, and the problems of Euclid are among the achievements of the brilliant Alexandrian period. The later Ptolemies appear to have been sunk in vice, and the dynasty came to an end with the Roman conquest and the death of Cleopatra.

Egypt became the private property of the Roman emperors, and until 1922 was never again an independent country. So jealous were the emperors of their possession that no senator was allowed to set foot in Egypt. The most important events under Roman rule were: the introduction of the Julian year by Augustus (B.C. 24), the introduction of Christianity in the 1st century A.D., the visit of Vespasian (A.D. 70) and of Hadrian (A.D. 122), the visit of Caracalla (A.D. 211), the development of Gnosticism, the conquest of Egypt by Zenobia (A.D. 270), the persecution of the Christians by Diocletian (A.D. 304), the rise of Manicheism, the great Arian controversy in the reign of Constantine, the rise of asceticism and monasticism, and the final destruction of paganism.

At the division of the Roman empire (A.D. 395) Egypt passed to the Eastern empire, and at its fall had become one of the great patriarchates of Christendom. But owing to the feud between the Jacobites and the Melkites (or Royalists, see COPTS), persecutions against the National Church (Jacobite) were constantly recurring. The Melkite governor, known as the Mukaukis, ruled the country in the name of Heraclius at the time of the Arab invasion; and, by the records that remain, it is evident that he betrayed Egypt into the hands of the Mohammedan general, 'Amr ibn el-Asr, who took possession of the country and made it a province of the Khalif Omar.

History since the Mohammedan Conquest.—The Moslem Arabs invaded Egypt at the close of 639, took Pelusium after a month's siege in 640, defeated the Romans at Bilbeys, and crushed their army at Heliopolis. The Egyptians (Copts), eager to be freed by any means from the tyranny of the Orthodox (Greek) Church, opened negotiations with 'Amr, the Arab general, and obtained generous terms. The country as a whole submitted. The Roman fortress of Babylon fell in 641, and Alexandria surrendered in the autumn (but was temporarily reoccupied for the Eastern empire in 645). From then to this day Egypt has been a Mohammedan country. From 641 to 969 it was a province of the Omayyad and 'Abbásid khalifate, ruled by governors of Arab and latterly of Turkish race. One of these last, Ahmad ibn Tālmān, made himself practically independent, annexed Syria, and founded the dynasty of the Tālmānids (868-905), renowned for its luxury and noble buildings. Another governor followed his example, and established the dynasty of the Ikshīdids (935-969). This in turn gave place to the heretical (Shi'a) line of the Fātimid Khalifs (q.v.), who advanced from their capital at Kayrawān, conquered Egypt, and founded modern Cairo (969) and the Azhar mosque. One of this line, the mad khalif El-Hākīm, was adopted as founder by the sect of the Druses (q.v.), who still pay him divine honours and expect his return. The long reign of El-Mustansir (1036-94) was marked by civil war, persecution of Christians, and a fearful famine which lasted seven years and depopulated whole quarters of Cairo. The Fātimids were deposed by the Kurd general, Salāh-ed-dīn (1169-93), son of Ayyūb, commonly called Saladin (q.v.), who fortified Cairo and built the Citadel. He waged war against the Crusaders, took Jerusalem, and annexed the greater part of Syria. In 1218 the Crusaders, under John of Brienne, made an attack upon Egypt and took Damietta; but the Ayyūbid sultan El-Kāmil, nephew of Saladin, defeated them at Mansūra in 1221, and they left the country. The attempt of St Louis, thirty years later, ended in the surrender of the French king and all his army to the Mamelukes (Mamlūks). It was the last of Saladin's line, Es-Sālih Ayyūb, who introduced this famous bodyguard of Turkish Mamelukes, or white slaves, who, on his death, usurped the supreme power (1250). For more than two centuries and a half Egypt was governed by kings of servile origin, called the Bahri or Turkish and the Burji or Circassian Mamelukes. These kings, who succeeded each other chiefly by virtue of force of arms, were distinguished for their valour, their administrative powers, their luxury, and their encouragement of the arts. They fought for the holy places of Palestine, and gallantly drove back the Mongol hordes; they exchanged embassies with France and Venice, with Persia and Abyssinia; and presented one of the most startling anomalies of history, the 'spectacle of a band of disorderly soldiers, to all appearance barbarians, prone to shed blood, tyrannous to their subjects, yet delighting in the delicate refinements which art could afford them in their home-life, lavish in the endowment of pious foundations, magnificent in their mosques and palaces, and the noblest promoters of art, of literature, and of public works that Egypt had known since the days of Alexander the Great' (Lane-Poole, *Art of the Saracens*). Cairo (q.v.) is still full of their monuments, and Arabic literature owes them much. In 1517, however, this brilliant series of rulers came to an end on the conquest of Egypt by the Ottoman sultan Selīm I.

Nearly three centuries of weak and corrupt government by Turkish pashas, varied by faction and rebellion of the Mameluke chiefs, happily relieved

by artistic and literary activity, bring us to the French invasion of Bonaparte in 1798. His conquest of Alexandria and victory near the Pyramids led to the temporary subjection of the country, from which the French were, however, expelled by the British after the battle of Alexandria in 1801, when the country was restored to the Porte. The accession of the Albanian soldier Mohammed 'Alī to the pashalik in 1805 imparted a galvanic prosperity to Egypt, by the merciless destruction of the turbulent Mamelukes (whom a disastrous British expedition in 1807 vainly sought to restore), the formation of a regular army, the increase of security, the improvement of the irrigation, and the introduction of the elements of European civilisation. From 1811 to 1818 Mohammed 'Alī waged war upon the Wahhābīs of Arabia, and subdued part of that country by the generalship of his son Ibrahim; in 1820 he annexed part of the Sudan and founded Khartūm, and from 1824 to 1828 his troops, under Ibrahim, occupied various points in the Morea and Crete to aid the Turks in their war with the insurgent Greeks. The Egyptian fleet was annihilated at Navarino, but Ibrahim remained in the Morea till forced to evacuate by the French army, under Maison, in 1828. In 1832 Ibrahim began the conquest of Syria, and totally routed the Ottoman army at Koniya; after which the Porte ceded the province to Mohammed 'Alī on condition of tribute. War breaking out again, the victory of Nezib in 1839 would perhaps have elevated him to the throne of Constantinople; but the quadruple alliance in 1840, the fall of Acre to Admirals Stopford and Napier, and the consequent evacuation of Syria compelled him to limit his ambition to the pashalik of Egypt, which was made hereditary in 1841. In 1848 Mohammed 'Alī became imbecile (he died in 1849), and his son Ibrahim sat on his throne for two months, when he died, and was succeeded by 'Abbās Pasha, Mohammed 'Alī's grandson, who was murdered by slaves in 1854, and succeeded by Sa'īd Pasha, youngest son of Mohammed 'Alī. M. de Lesseps now obtained the co-operation, hitherto withheld, of the Egyptian government in his scheme of the Suez Canal (q.v.), which was opened in 1869. Sa'īd was succeeded in 1863 by his nephew, Isma'īl, son of Ibrahim, who, by a firman purchased from the Sultan by nearly doubling the Egyptian tribute, took in 1867 the hereditary title of Khedive; the succession to the throne of Egypt was made direct from father to son, instead of descending, according to Turkish law, to the eldest male of the family; and in 1872 the Sultan granted to the Khedive the rights (withdrawn in 1879) of concluding treaties and of maintaining an army, and virtually gave him sovereign powers. Thus secure on a hereditary throne, Isma'īl began a series of vast internal reforms, built roads, bridges, lighthouses, laid down railways and telegraphs, reconstructed the postal service, improved the harbours at Suez, Port Said, and Alexandria, supported education, and introduced mixed courts of law. Extending his dominions southward, he annexed Dar-Fūr in 1874, and in that and the following year further conquests were made. In order to provide funds for his vast undertakings, in 1875 he sold to Great Britain 177,000 shares in the Suez Canal for £4,000,000. The condition of the Egyptian finances, however, loaded by heavy loans, was almost hopelessly involved; various distinguished financiers were sent from England to endeavour to arrange a solvent system, and after many inquiries and several failures, a dual English and French Control was established, and the finances were placed entirely under European management. A promise of constitutional government ended in 1879 in the summary dismissal of Nubar Pasha's ministry, and this brought about the prepotent interference of

the European governments. The Khedive, who declined to abdicate, was, at the instance of the Western Powers, deposed by his suzerain the Sultan in June 1879, and Prince Tewfik, Isma'il's eldest son, was proclaimed Khedive.

The British Occupation.—A Law of Liquidation for regulating the conditions of the public debt was passed at the instance of five European Powers in 1880. In the next year came the military revolt under 'Arabi Pasha, fomented by general discontent, jealousy (not only of European influence, but of Turkish and Circassian favouritism in the army promotions), and perhaps the germs of nationalist aspirations towards autonomy. 'Arabi demanded from the Khedive an immediate change of ministry and the increase of the army to 18,000 men. He became practically a military dictator, and in 1882 British and French war-ships were despatched to Alexandria to overawe the rebels, but their appearance was followed in June by rioting and massacres of Europeans in the streets. Meanwhile 'Arabi was strengthening the fortifications. The British admiral demanded that the work should be discontinued. 'Arabi persisted; the French fleet sailed away, and the British ships bombarded the fortifications (11th July). The Egyptian troops were suddenly withdrawn from Alexandria, whereupon the city was plundered and partly burned by Egyptian rioters; while the British admiral, Sir B. Seymour (Lord Alcester), was apparently unable to land a force to restore order until the third day, when he occupied the city until the arrival of troops under Sir A. Alison, who kept 'Arabi in check behind his lines at Kafr Dawar. Meanwhile Sir Garnet Wolseley hurried out with more troops from England, and other regiments (some native) were despatched from India; the point of debarkation was Ismailia, on the Suez Canal; and in twenty-five days the British forces under Wolseley had traversed the desert, utterly defeated the main body of 'Arabi's army at Tell-el-Kebir (13th September), and occupied Cairo. 'Arabi was tried, pleaded guilty, and was banished to Ceylon. (He was allowed to return to Egypt in 1901, and lived there in harmless obscurity till his death in September 1911.) The authority of the Khedive being thus restored, most of the British troops were withdrawn, and measures taken for the reorganisation of the country. Lord Dufferin went to Cairo after the war, and drew up a constitution which remains illusory; and Sir E. Baring (afterwards Earl of Cromer) continued the task of organisation. But the attempt to persuade the Khedive's government to rule according to British ideas, and to get British officials and their Egyptian colleagues to work smoothly together, led to repeated crises and changes of plan. A conference of the great Powers in 1884, and a subsequent negotiation with Turkey in 1886, did not relieve Britain of her exclusive responsibility; and the resuscitation of Egypt under British rule was hindered by the severe visitation of cholera which occurred in the summer of 1883, when 150,000 persons perished, and still more by the rebellion in the Sudan.

The Rebellion in the Sudan.—'Arabi's revolt and its consequences loosened the hold of Egypt on the Sudan (q.v.), which by Baker's annexations in 1874 and following years had gradually extended to the shores of the Victoria Nyanza. A widespread rebellion broke out in Dar-Fur and Kordofan under Mohammed Ahmed, calling himself the *Mahdi*, or 'guided by God' (see ISMAILIS, MOHAMMEDANISM, and KARMATHIANS). He was born at Dongola about 1843, educated near Khartum, and then spent fifteen years in fasting and retirement in the island of Aba, whence he at length sent emissaries to preach the doom of Turkish rule in the Sudan

and the advent of the true Mahdi. An attempt of Raïf, the governor-general, to suppress this propaganda was resisted with bloodshed in August 1881, and thenceforward the movement spread rapidly. In January 1883 Sennâr revolted, and the Mahdi occupied El-'Obeid. An untrustworthy army sent by the Egyptian government under an English officer, Hicks Pasha, was annihilated near El-'Obeid in November 1883. The Mahdi's influence was extended to the Red Sea shores by his lieutenant, Osman Digna. An Egyptian force under Consul Moncrieff was routed with severe loss in the same month near Snâkin, and Baker Pasha was disastrously defeated at Tokar early in 1884; but these reverses were wiped out by the hard-won successes of a British expedition under Sir G. Graham at Teh and Tamanieb. Meanwhile, in January 1884, General Gordon (q.v.), who had previously done good work in the Sudan from 1874 to 1879, had gone, at the request of Mr Gladstone's government, as English representative to Khartoum, to secure the withdrawal of the Egyptian garrisons from the Sudan; for Egypt had, on the advice of England, reluctantly agreed to give up all her possessions in the Sudan save the Red Sea littoral. Gordon, though supported by only one other English officer, gallantly maintained his position in Khartoum against the Mahdi's followers, and even ventured successfully on the aggressive. He had found, however, that he had attempted an impossible task; he could not leave the garrisons to fall into the hands of the Mahdi, and he required reinforcements of British troops before he could drive the latter from the neighbourhood of Khartoum. Timidity and indecision marked the whole of the policy of the English government, both towards the Sudan and the Red Sea littoral. At last, too late, in October 1884, an English expedition under Lord Wolseley was despatched, and selected the difficult and tedious route up the Nile, instead of making a rapid dash from Snâkin to Berber. A flying column sent across the desert from Korti in advance of the main army encountered determined opposition, but after defeating the Mahdi's forces, generally known as the dervishes, at Abu-Tia (Klea), 17th January 1885, reached the Nile at Metemma, with the loss of its commander Sir Herbert Stewart and General Burnaby. At Metemma the harassed column found some of Gordon's steamers awaiting them, on which, after some inevitable delay, a small advanced party under Sir C. W. Wilson embarked. They came in sight of Khartoum only to learn that it had already fallen, and that the heroic Gordon had been killed on 26th January. There was nothing to be done, and they made their way back to Metemma under a heavy fire; the energy of Lord Charles Beresford and his sailors alone saved them from destruction. The main object of the expedition having failed, the army was hastily withdrawn, and the Sudan was left to its fate. For eleven years it was abandoned to an appalling reign of terror, which left it desolate, devastated, depopulated, and paralysed with dread. The Mahdi, a cruel voluptuary as well as an impostor, died in June 1885, and was succeeded by his lieutenant, or *khalifa*, 'Abdallah, an even worse brute than his master, of whose savage sway ample accounts were brought by escaped prisoners, such as the Austrian officer Slatin Pasha. Reconquest was of course inevitable, for the Sudan commands the water and hence the wealth of Egypt. The folly of the abandonment of 1883 and the shame of 1885 had to be wiped out. It took time, however, to organise an Egyptian army that could be trusted, and for four years all that could be done was to hold the frontier at Wadi Halfa and keep the dervishes out of Egypt proper. General Grenfell's victory with Egyptian

troops over the dervishes at Toski on 3d August 1889 showed that the persistent work of Sir Evelyn Wood, Grenfell himself, and Kitchener had at length produced an efficient native force; and this was confirmed by the defeat of Osman Digna at Afafit in 1891, which freed the Red Sea littoral. In 1892 Sir Herbert (afterwards Earl) Kitchener became *Sindar* of the Egyptian army, and after four years of steady preparation he made the move to the south. The victory over the dervishes at Firkā on 7th June was followed by the capture of Dongola in September 1896. A railway—Kitchener's potent aid—was thrown across the desert to Abu Hamed, the dervishes retreated from Berber, and in 1898 they were driven out of their entrenchments on the Atbara river, 7th April, by a combined Egyptian and British army; and on 2d September, with 22,000 men, Kitchener, ably supported by Hector Macdonald, Hunter, and others, won his crowning victory at Omdurman over 40,000 of the enemy. Khartūm was taken. The khalifa escaped, but was run to earth, 24th November 1899, by Sir Reginald Wingate, and died fighting to the last, surrounded by his no less desperate emirs. Immediately after Omdurman, Kitchener went up the Nile to Fashoda, where he found that a small expedition under Major Marchand had hoisted the French flag. The difficulty was diplomatically arranged, and Marchand departed in December. What is technically described as an Anglo-Egyptian 'Condominium' was established in the Sudan, 19th January 1899, under Kitchener as the first governor-general; and on his appointment to the South African command Wingate succeeded. The total loss of men in the reconquest of the Sudan in seventeen engagements (1885-99) was but 536 killed and 1810 wounded, and the cost of the campaigns of 1896-98 was £2,350,000, of which the railways accounted for about half. The restoration of a devastated, depopulated province of a million square miles to prosperity has necessarily been a work of time, labour, and economy. Much has been accomplished. Khartūm, which has been rebuilt, is now connected by rail with Cairo, and Berber with Port Sudan on the Red Sea, a valuable outlet for trade. The Gordon College in the capital is introducing a carefully planned system of education. Slave-dealing has been practically exterminated, and with the gradual recovery of population, and with it of agriculture, the financial condition has greatly improved. With enlarged irrigation the Sudan will soon pay its own way.

Egypt under Lord Cromer.—Meanwhile Egypt, relieved from the apprehension of the Mahdi, was gradually recovering from the state of anarchy and debt in which Isma'il had plunged her. This restoration to order and solvency is mainly the work of one man, the Earl of Cromer, 'the man who has made modern Egypt.' 'In less than twenty-four years Egypt, under the guiding hand of Lord Cromer, has risen from bankruptcy and abject misery to her present state of opulence and credit. Never in all her long and varied annals have the masses of her people enjoyed as they now enjoy the blessings of a just and orderly and enlightened rule. That rule is the creation of Lord Cromer' (*Times*, 13th May 1907). A financier by birth, he perceived that the key to the whole difficulty lay in the financial muddle. It was for many years a fight with bankruptcy, and this is the explanation of the abandonment of the Sudan in 1883. Money was wanted for irrigation, the prime necessity of Egypt, as well as for every kind of reform. A modification of the law of liquidation, sanctioned by the London Convention of 1886, gave Lord Cromer a freer hand, and irrigation works were begun. The repair of the barrage of the Nile by Sir C. Scott-Moncrieff in 1890, and the great dams at

Assuan and Asyūt, began in 1898, and carried to a successful issue by Messrs Aird, have together added at least £3,500,000 a year to the value of the country's productiveness, and every peasant now gets his share of water for his field as well as the richest landowner. Taxes, no longer collected under the whip, were in great measure remitted, and the total taxation per head fell; yet the revenue rose. The finances were brilliantly managed. Most significant of all, the educational budget has increased fivefold. Such was the triumph of Lord Cromer's unremitting toil for nearly a quarter of a century. He found Egypt ruined, outraged, and miserable; he left it in 1907 prosperous, wealthy, and one of the lightest-taxed countries of the civilised world. His work was accomplished in the face of strenuous opposition, from the Powers, the Sultan, and a venomous native press; and international restrictions hampered him at every turn. The Anglo-French Agreement of 1904, which at last removed all causes of friction between English and French interests in Egypt, together with most of the financial restrictions which had obstructed progress, was not the least of his conspicuous successes. He was succeeded by Sir Eldon Gorst, on whose death in 1911 Lord Kitchener was appointed British agent and Minister Plenipotentiary. Sir John Maxwell was appointed during the war, and was succeeded by Lord Allenby.

Railways.—There are now over 2000 miles of railway in Egypt (excluding the Sudan), besides 800 miles of invaluable light railway for agricultural produce. There are 1500 miles of railway in the Sudan. That from Wady Halfa to Khartūm, made for military purposes during the reconquest, was opened for general traffic in 1889; and the connection between Berber and the Red Sea at Port Sudan (near Suakin) was opened in 1905.

Statistics.—The area of Egypt, including the Libyan oases, but excluding the Sudan, is about 400,000 sq. m., of which, however, the greater part is desert or water, and only 12,000 sq. m. can be regarded as settled and cultivated. Of the population (1917) of 12,750,918, foreigners numbered only 200,000 (of whom about 56,000 were Greeks, 40,000 Italians, 30,000 Turks, 21,000 French, 24,000 British). The males exceeded the females by 50,000. Of the native population, over 4,000,000 are engaged in agriculture; half are classed as 'unproductive or unknown occupation' (this includes the women, who are certainly not unproductive), and of the remaining fourth, about 489,000 are engaged in manufactures, 280,000 in trade, 230,000 in professions of various kinds, 136,000 live on their incomes, and there are nearly 100,000 nomads. Of the population over ten years of age 62·65 per cent. are engaged in agriculture. In religion, 11,600,000 (in round figures) are Mohammedans, 856,000 Copts, 77,000 Greek Orthodox, 107,000 Roman Catholics, 47,000 Protestants, 59,000 Jews. The population of the chief towns is as follows: Cairo, 791,000; Alexandria, 445,700; Port Said, 91,000; Tanta, 74,000; Asyūt, 51,000; between 30,000 and 50,000, Mansura, Fayūm, Zagazig, Damanhūr, Minya, Suez, Damietta, Benī-Suwayf; smaller towns are Sherbīn, Ekhmīm, Menūf, Mellawī, Kinē. The population (in 1917, 1057 per sq. mile) has well-nigh doubled since 1883, and the trade has grown to £96,000,000, of which rather less than half consists of exports, notably the splendid yield of cotton.

Government.—The administration till the entry of Turkey into the great European war (December 1914) was conducted by native ministers under the Khedive 'Abbās II. (who succeeded on the death of his father, Tewfik, 7th January 1892), but with English departmental advisers. A British protec-

orate was then proclaimed, the Khedive deposed, a prince of the same dynasty set up as sultan, and a British High Commissioner for Egypt was appointed. Though obstruction was not unknown, neither the General Assembly nor the Legislative Council had attained to any degree of influence when they were amalgamated in 1913. The Legislative Assembly thus formed was partly elected, partly nominated. Agitations, encouraged by the Turkish revolution, culminated in the murder of the Copt Boutros Pasha, the prime-minister. The situation had become acute in 1919 when a commission under Lord Milner was sent to work out a plan for a constitution. The High Commissioner proclaimed that the policy of Great Britain was to preserve autonomy under British protection, and to develop self-government. In 1922 Great Britain declared the independence of Egypt, and in 1923 the new constitution was signed. Egypt now claims suzerainty over the Sudan. The provinces are administered by fourteen local councils under the mudir, with limited power (granted 1910) to make by-laws; and five towns are under governors.

Ehrenberg, CHRISTIAN GOTTFRIED (1795-1876), naturalist, born at Delitzsch in Prussian Saxony, travelled in Egypt, Syria, and Arabia, and with Humboldt in the Ural and Altai Mountains, and by a score of works on microscopic organisms founded a science.

Ehrenbreitstein, a town and fortress of Rheinland, is picturesquely situated on the right bank of the Rhine, directly opposite Coblenz, with which it is connected by a bridge of boats and an iron railway-viaduct; pop. 3000. The fortress occupied the summit of a precipitous rock, 387 feet above the river and inaccessible on three sides; on the N. and NW. very strongly fortified. The French captured it in 1799; in 1815 it was assigned to Prussia by the Congress of Vienna, and in 1816-26 was thoroughly refortified. The fortifications were razed in accordance with the Treaty of Versailles.

Ehrlich, PAUL, a great bacteriologist and chemotherapist, was born of Jewish family at

Strehlen, in Prussian Silesia, 14th March 1854, and educated at Breslau gymnasium and the universities of Breslau, Freiburg, Strassburg, and Leipzig, graduating in medicine. He worked in various institutes in Berlin, a professor from 1881. Later he was director of the institutes of experimental therapy and chemotherapy at Frankfurt-on-the-Main. He died in his laboratory at Homburg, 20th August 1915. Interest in the affinities of chemical reagents for living matter underlies his work from his early studies of aniline dyes to his world-famous discovery of salvarsan in 1910. New stains invented by him came into general use for microscopical and other scientific purposes. He found that certain dyes had a specific affinity for the tubercle bacillus. Applying these methods to the study of blood corpuscles, he became a pioneer in hamatology. One of the founders of serum-therapy, he conducted important researches on immunity and on diphtheria antitoxin and its standardisation. Cancer occupied his attention for a time. He then attacked the disease-bringing parasitic protozoa. His 'trypan red' dye is a valuable means of killing certain trypanotomes in animals, though no cure for trypanosomiasis in man. Methodical tests of a series of compounds of arsenic and mercury led to the discovery of a specific for Syphilis (q.v.), 'salvarsan'—an excellent example of experimental industry directed by imaginative reason. See the *Festschrift* for his sixtieth birthday (1915).

Eibenstock, a lace-making town of Saxony, 41 miles SSW. of Chemnitz; pop. 9000.

Eichendorff, JOSEPH, FREIHERR VON (1788-1857), last of the romantics, a Silesian, fought with distinction in the War of Liberation, wrote poems, short novels, and a history of German poetry from a Catholic standpoint.

Eichhorn, JOHANN GOTTFRIED (1752-1827), professor of Oriental languages at Jena and Göttingen, in his introductions to the Old and New Testaments applied the ordinary methods of literary criticism to Scripture. He is chiefly remembered for his hypothesis of the origin of the Gospels (q.v.).

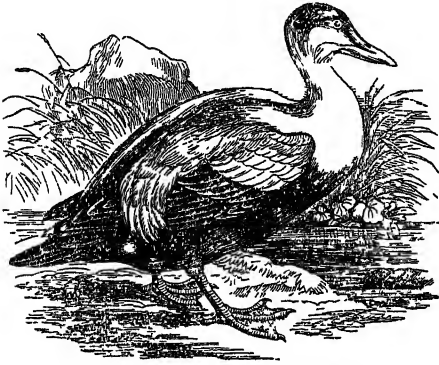

Eichstätt, in Bavaria, 67 miles NNW. of Munich, became a bishopric in 745, and was long capital of a small principality; pop. 8000.

Eichwald, CHARLES EDWARD (1795-1876), born at Mitau, filled chairs at Kazan, Vilno, and St Petersburg; travelled in Central Asia, the Caucasus, Persia, Switzerland, and Scandinavia; and wrote on his scientific journeys, the mineral wealth, zoology, and palæontology of Russia.

Eider, a river forming the boundary between Sleswick and Holstein, rises SW. of Kiel, and flows westward to the North Sea at Tönning, after a course of 117 miles. It is navigable as far as Rendsburg, whence the Eider Canal (1777-84) maintained water-communication between the North Sea and the Baltic (Kiel Harbour) until superseded by the Kiel Canal (see BALTIC SEA).

Eider-duck (*Somateria*), a genus of birds in the duck family (Anatidæ), included under geese (Anseres). The Common Eider-duck (*S. mollissima*) lives on the Arctic and northerly shores of the Atlantic in both hemispheres, and breeds as far south as the Farne Islands (where they are called St Cuthbert's ducks) and the Bay of Fundy in America. About 2 feet in length, it is heavy for its size. Of the females and young males the colour is rusty brown, with dark streaks and spots. The adult males, however, have a more complex plumage, especially in the breeding season. The crown of the head, the under surface, and tail are black; the cheeks are sea-green; while white prevails over the neck and upper surface. After breeding, black prevails. The fine elastic gray down, so much used, especially on the Continent,

for bed-coverlets, is chiefly developed on the breast of the bird. The best quality is not taken from the bird directly, but gathered from the nest; each nest furnishing annually about a quarter of a pound. The nest among the rocks is formed of fine seaweeds, often matted along with mosses and twigs. The female does the brooding; when the brood is hatched, the mother pillages her breast for down to serve as covering. The down is often carried off

Common Eider-duck, Adult Male.

two several times by the eider-down gatherers, and then the male may pluck off his slightly inferior feathers if the mother has no more to spare. The flesh is eaten by Greenlanders and others. The eggs are more esteemed. It seems probable that with a little care the duck might be domesticated on some of the Scottish islands. The King-Eider (*S. spectabilis*), whose down is also collected, is about the same size, but of different colour; it lives in the far north of Asia and America, and a few breed in Iceland and the Farøe Islands. There are three other species.

Eifel, THE, a barren and bleak plateau of Rheinland, between the rivers Rhine, Moselle, and Roer, showing extensive traces of volcanic activity. Its surface, which ranges at an average altitude of 1500 to 2000 feet, is for the most part broadly undulating, and diversified by crater-like depressions and volcanic peaks and ridges, whilst towards its edges it is seamed by deep, wooded, rocky ravines. Its highest and, at the same time, most inhospitable parts are in the west and north-west, whence it falls away gradually to the Rhine on the east, and to the Moselle on the south. The central portion of the plateau is crossed by a range of basaltic summits, the loftiest in the Eifel system, including the Hohe Acht (2494 feet), Nürburg (2255), and Kellberg (2211). The ridges of the north-west are connected by the Hohe Venn with the Ardennes. Geologically, the basement of the plateau belongs to the Lower Graywacke of the Devonian formation, with interruptions of Eifel limestone, parts of which are rich in fossils. Above this are deposited, with tolerable regularity in a horizontal position, strata of Triassic age, containing considerable quantities of metallic ores, especially zinc and lead. The Eifel was for a long period the scene of volcanic activity; zones and islands of basalt are frequent, as also eruptive masses of basaltic lavas, with tufa and pumice. With the exception of the vine and fruit trees on the east and south edges of the plateau, and a little agriculture (up to 1700 feet), the Eifel is uncultivated, its rocky soil being too poor, and its climate too raw and bleak for anything to grow but heather.

Eiffel, GUSTAVE, engineer, born at Dijon, 15th December 1832, was in 1858, only three years after

completing his studies at the Ecole Centrale, intrusted with the construction of the large iron bridge over the Garonne at Bordeaux, and was one of the first to introduce caissons worked with compressed air. The bridge over the Douro at Oporto, the great viaduct of Garabit, in Cantal (described by him in an elaborate monograph, 1889), and that over the Tardes, near Montluçon, and the gigantic locks designed and partly prepared for the Panamá Canal were among his most notable achievements and designs; while in the huge framework erected for Bartholdi's statue of Liberty may be seen the germ of the idea which afterwards assumed the form of the colossal iron structure (1887-1889) on the Champ-de-Mars in Paris with which his name is identified. The Eiffel Tower contains three stories, reached by a series of elevators or lifts, and the platform at the summit is 300 metres (985 feet) above the ground. About 7,000,000 kilogrammes (a little less than 7000 tons) of iron were employed in its construction; the cost was about £260,000, of which £60,000 was voted by the state, and the remainder supplied by M. Eiffel, who expected to recoup himself out of the admission fees during the twenty years for which he held a concession. The tower has been used since 1910 as a wireless station. In 1893 he was condemned to two years' imprisonment and a fine of 20,000 francs for breach of trust in connection with the Panamá Canal works. In his old age he took up research in meteorology and in air-resistance in relation to aviation. He published an annual *Atlas Météorologique, Recherches expérimentales sur la résistance de l'air* (1907), and *L'Héliée aérienne* (1920). He died in December 1923.

Eigg, or **EGG**, a Hebridean Island, $7\frac{1}{2}$ miles W. of the mainland of Inverness-shire, and 5 SW. of Skye. With an utmost length and breadth of $6\frac{1}{2}$ and 4 miles, it is 12 sq. m. in area, and culminates in the remarkable Scur of Eigg (1346 feet), near which are columnar cliffs like those of Staffa. Here in 617 St. Donnán and fifty more monks from Iona were killed by the queen, though her people objected that 'that would not be a religious act;' and here, towards the close of the 16th century, 200 MacDonalds, men, women, and children, were smoked to death in a narrow-mouthed cave by Macleod.

Eight, PIECE OF. See PIASTRE.

Eikon Basilike, a work whose full title is *Εἰκὼν Βασιλική: The Portraiture of His Sacred Majesty in his Solitudes and Sufferings*. It was published immediately after the execution of Charles I. (1649), and within a twelvemonth ran through fifty editions in various languages. Written in the first person, it professes to be Charles's own composition, and if it be a forgery, it is certainly one of the cleverest of the kind. It is no blind apology, for, to take but a single example, it does not vindicate the death of Strafford: 'I,' says its author, 'am so far from excusing or denying that compliance on my part (for plenary consent it was not) to his destruction, whom in my judgment I thought not, by any clear law, guilty of death, that I never have any touch of conscience with greater regret.' Though Milton and others did at the time insinuate doubts whether the work was not by some secret coadjutor, doctor or prelate, yet generally it was accepted as the king's, until, in a fifteen months' correspondence (1660-62) with Clarendon and the Earl of Bristol, Dr John Gauden (q. v.) laid claim to the sole authorship: 'This book and figure [the frontispiece] was wholly and only my invention, making, and design, in order to vindicate the King's wisdom, honour, and piety.' Gauden professed to have begun the work in or about the year 1647, and to have submitted a MS. copy of it to the king 'in the Isle of Wight, by the favour of the late Marquis of Hertford, which was delivered to the king by the now Bishop

of Winchester.' On the other hand, some assert that Charles had written the first six of its twenty-eight chapters before the battle of Naseby (1645). The question, one of much complexity, is not yet settled either way; to discuss it thoroughly is here impossible. Enough, that historians generally, from Lingard to Green, have pronounced against Charles; whilst some of those who have sifted his claims are in his favour, as Dr C. Wordsworth, in *Who wrote Eikon Basilike?* (1824-28), and E. J. L. Scott, in his edition of the work (1880). But see W. D. Odgers in the *Modern Review* (1880), Doble in the *Academy* (1883), and E. Almack's *Bibliography of the King's Book* (1896).

Eildons, a triple-crested height in Roxburghshire, due south of Melrose, whose middle and highest peak (1385 feet) commands a glorious view. 'I can stand,' said Scott, 'on the Eildon Hill, and point out forty-three places famous in war and verse.' Of an older magician, and of an older poet, the Eildons also have memories—Michael Scott and Thomas the Rhymer. Newstead, at their foot, has the great Roman camp of *Trimontium*.

Eilenburg, a town of Prussian Saxony, on an island in the river Mulde, 15 miles by rail N.E. of Leipzig, has manufactures of cloth, calico, tobacco, chemicals, beer, hardware, furniture, and agricultural implements; pop. 18,000.

Eilethya (hieroglyph. *Nekhob*; city of Lucina, now called El-Kâb), a city of ancient Egypt, situated on the right bank of the Nile, a little below Edfu. The present ruins consist of the remains of small temples dedicated by Rameses III. to Ra; a Ptolemaic temple dedicated to the eponymous goddess Lucina by Physcon or Euergetes II., with additions by Ptolemy Alexander I. and the elder Cleopatra; and an ancient temple dedicated by Amenophis III. to the local deities. The names of other monarchs are also found in the ruins; but the most interesting and important remains are the rock-tombs, some as early as the 13th dynasty, excavated in the hills. That of Aahmes, the 'captain of the sailors,' records his services in the wars of the early monarchs of the 18th dynasty against the Hyksos or Shepherds, and other Asiatic and Nigritic races. Another, that of Pahir, is decorated with rich and elaborate paintings representing the pursuits of agriculture, fowling, fishing, &c. The city was an outpost against the southern tribes, and its fort, a large inclosure of crude brick, was of importance as early as the Shepherd war. The goddess Suben (Eilethya or Lucina) was a special protectress of Upper Egypt.

Eimeo (called by the French *Moorea*), one of the French Society Islands, in the Pacific Ocean, about 10 miles WNW. of Tahiti, the principal member of the group. Area, 51 sq. m.: pop. about 2000. It consists of deep valleys and abrupt hills—the former well cultivated, and the latter heavily timbered. Here Christianity was first introduced in Polynesia; and here the South Sea College of the London Missionary Society was established. Most of the natives are Protestants.

Einbeck, or EIMBECK, a town of Hanover, is situated on the Ilme, 23 miles N. of Göttingen by rail. Although a place of considerable importance in the 15th century, and a Hanse city, it has decayed greatly in recent times. It manufactures sugar, tobacco, carpets, &c. Einbeck was noted in the 15th century for its beer (*Einbecker Beer*, whence 'Bock'). The town suffered severely in the Thirty Years' War; and in 1761 the French demolished its walls. Pop. 10,000.

Einhard. See EGINHARD.

Einsiedeln, a town of Switzerland, in the canton of Schwyz, 27 miles S.E. of Zurich by

rail. Pop. 8500. In Einsiedeln great numbers of prayer-books, sacred images, wax candles, rosaries, medallions, &c. are made. The town is, however, chiefly celebrated for its Benedictine abbey, to which some 200,000 pilgrims resort annually to worship at the shrine of a black image of the Virgin, the 14th September being the principal day in the year. The abbey itself was founded in the 10th century, and after being repeatedly destroyed by fire, was rebuilt as a quadrangle in the Italian style in 1704-19. It contains a valuable library, with several incunabula and MSS., these last dating from the 8th to the 12th century; also a museum of natural science and natural history. Rudolph of Hapsburg elevated the abbot of Einsiedeln to the dignity of a prince of the empire in 1274. Near the town the Austrians under Jellachich were defeated by the French under Masséna on 14th August 1799.

Einstein, ALBERT, mathematical physicist and astronomer, elaborator of the theory of Relativity (q.v.), which is working a revolution in conceptions of space, time, and gravity, and is perhaps the profoundest influence in the thought of the time, was born at Ulm, in Württemberg, 14th May 1879, son of a Jewish manufacturer. He spent part of his childhood at Munich, and went to school at Aarau, in Switzerland. He studied mathematics and physics at Zurich University, taught in the technical high school in that city. Afterwards he was employed in the patent office at Bern. Meanwhile he had published papers on various physical subjects, such as the Brownian movements. His earlier and narrower theory of relativity was enounced in 1905. In 1909 he became extraordinary professor at Zurich, in 1911 professor of physics in the German university of Prague, and in 1912 returned to Zurich technical high school. In 1913 he was elected a member of the Berlin Academy of Sciences, and a sinecure professorship enabled him to devote all his time to research and the direction of the Kaiser-Wilhelm Institut für Physik. His generalised theory of relativity was put forth in 1915. Later a chair was provided for him at Leyden, to be held along with his Berlin chair, three weeks to be spent every year at Leyden. A democrat and pacifist, Einstein signed the protest against the manifesto of those men of science who approved of the Great War, joined in an appeal in favour of the German revolution, and worked for the League of Nations. As a Jew and a Zionist he was subjected to annoyance by Berlin anti-Semites, and offered his co-operation in the work of the proposed university of Jerusalem. See, for his theories, his own *Relativity: the Special and the General Theory* (trans. R. W. Lawson, 1920), and the article RELATIVITY in this Encyclopædia.

Eisenach, a town of Weimar (Thuringia), is beautifully situated on the Horsel, at the north-western verge of the Thuringian Forest, 69 miles by rail S.E. of Cassel, and 49 W. of Weimar. Once the capital of a principality, Eisenach is still a thriving and industrious town, with wide, clean, and well-paved streets. It has a ducal palace (1742), now used as a court-house; a spacious market-place, and manufactures of art pottery, leather, &c. Sebastian Bach, of whom a statue was erected in 1884, was a native; and Fritz Reuter died at Eisenach in 1874. Pop. (1875) 16,163; (1919) 41,375.

On an eminence rising 600 feet above the town, engirt by forests, stands the castle of Wartburg, founded in 1067, and till 1440 the residence of the Landgrave of Thuringia. It is famous as the spot where the Minnesingers (q.v.) assembled to hold a poetic contest ('the war of the Wartburg') about 1207; as the home of St Elizabeth (1511-27); and

as the ten months' asylum to which Luther was carried by the Elector of Saxony (May 1521). The chapel in which Luther preached, as well as the chamber which he occupied, and in which he discomfited the Evil One by throwing the inkstand at his head, is still pointed out. The whole pile has been magnificently restored since 1851. See WALTHER VON DER VOGELWEIDE, WOLFRAM VON ESCHENBACH; also TANNHAUSER.

Eisenberg, a town of Germany, in the state of Thuringia, on an eminence between the Saale and the Elster, 36 miles SE. of Leipzig; pop. 10,000.

Eisenerz, a mining-town of Austria, in the north of Styria, 20 miles NW. of Bruck. It stands in a narrow mountain-valley at the north foot of the Erzberg (5000 feet), a mountain so rich in iron ore that the miners, instead of cutting mines into it and following the metal in veins, quarry the rock from the outside; the ore is then broken small, and conveyed to the smelting-house without further preparation. The ore is very rich in metal. Azag-onite (*Eisenblute*, or *flos ferri*), resembling branching coral in form, and of the most beautiful and purest white, is found in grottoes in the interior of the mountain. Pop. 6000.

Eisenstadt, a walled town of Austria, 26 miles SE. of Vienna. The Esterhazy palace (1683-1805), in the centre of the town, contains a valuable library.

Eisleben, Luther's birthplace, a town of Prussian Saxony, 24 miles WNW. of Halle. Once the capital of the counts of Mansfeld, it is the centre of a rich mining district. Pop. (1875) 14,378; (1919) 22,713. The house in which Luther was born was partially consumed by fire in 1689, but was restored, as also have been the house in which he died, the church (Peter-Pauls-kirche) where he was christened, and another (Andreaskirche) in which he preached. In 1883, on the occasion of his quatercentenary, a bronze statue was unveiled of the Reformer, and a new gymnasium inaugurated, successor to the one which he founded two days before his death. See Grossler's *Geschichte Eislebens* (Halle, 1875).

Eisner, or KOSMANOWSKY, KURT, leader of the Bavarian revolution of 1918-19, was born, a Jew, in Berlin, 14th May 1867. A member of the staff of *Vorwärts* and other socialist papers in Berlin, Nürnberg, and Munich, he was several times imprisoned for his writings, as in 1918, when he opposed the war. On his release he held a great meeting in Munich, overthrew the monarchy, and became president of the Bavarian republic. He opposed centralisation in the Reich. Leaning towards the council system, he accepted a National Assembly, and on his way to open its first sitting was assassinated in Munich, 21st February 1919. An idealist of great 'personal magnetism,' he wrote a number of meritorious books. His *Gesammelten Schriften* (not quite complete) were published in 1920.

Eisteddfod, the name given to a congress of Welsh bards and musicians, having for its object the preservation and cultivation of the national poetry and music, and in a secondary degree of the national customs and traditions. In very early times contests took place at Caerwys in Flintshire, and at other towns, when degrees were conferred upon the successful competitors, the honours thus won procuring the bard's ready admittance into the castles of the Welsh princes and nobles. Eisteddfods are known to have been held in the reigns of Edward III. (1327-30), Henry VI. (c. 1451), Henry VIII. (c. 1525), and Elizabeth (1568). Then for a couple of centuries the contests seem to have

been discontinued, but were revived in 1798, after which date they were frequent for a time. See *The Welsh People* (1900), by Rhys and Brynmor Jones.

Ejectment (*Ejectio firmæ*) was, in English law, a form of possessory action, wherein the title to land might be tried, and the possession recovered. Under the old common law, a person dispossessed of his freehold was often obliged to have recourse to the cumbrous forms of a real action. A lessee for years, on the other hand, if dispossessed, could only claim damages for ejectment; but at an early period the courts decided that he should not only have his damages, but recover possession of the land. By means of an elaborate series of fictions, the action for ejectment was made to serve the purpose of any person claiming title to land. If Smith wished to recover land from Brown, he commenced his action with a declaration, every word of which was untrue, setting forth that Smith had made a lease to John Doe; that Doe entered on the land; that Doe was wrongfully ejected by one Richard Roe, and claimed damages accordingly. Brown, the actual possessor, was admitted to defend the action, in place of the imaginary Roe, but only on agreeing to admit the truth of the story about Doe; so that the only question in dispute was whether Smith had a right to make the lease to Doe. This curious legal comedy was abolished by the Common Law Procedure Act of 1852, and the Judicature Acts have now substituted an action for the recovery of land for the action of ejectment. But the term ejectment is still commonly used to describe the various forms of process by which a person in possession of land or house property may be turned out by his landlord or by a rival claimant. See EVICTION.

Ekaterinburg, now SVERDLOVSK, a fortified town of Russia, on the eastern slope of the Urals, and on both banks of the Isset, 312 miles SE. of Perm by rail. It has wide, straight streets, with two cathedrals, a monastery, and a mint for copper coinage. It is the centre of the Ural mining districts. Its manufactures include machinery, soap, candles, and linen, and it has large iron and copper works, besides establishments for washing gold and cutting and polishing precious stones. Industries are mining, cattle-rearing, and (among the Bashkirs of the suburbs) the keeping of bees. It was at Ekaterinburg that Nicholas II. and his family were put to death, 16th June 1918. A university was founded in 1920. Pop. 70,000.

Ekaterinodar, a town of Russia, capital of the country of the Kuban Cossacks, on the Kuban River, about 100 miles from its mouth. It is surrounded on all sides by swamp and morass; it has a cathedral and a large military hospital, but its houses are mostly of earth, with low, thatched roofs. A university was founded in 1920. The town has been renamed Krasnodar. Pop. 143,000.

Ekaterinoslav, a government of Ukraine, reaching in the south-east to the Sea of Azov, with an area of 26,000 sq. m., and a pop. of about 2,000,000, mostly engaged in agriculture and the rearing of cattle. It forms, except in the north-east, a vast plain, with stretches of steppe, although most of the land is well watered; 53 per cent. is arable, and good crops are raised, while melons, apicots, peaches, and grapes do well in spite of the night-frosts. The climate is generally mild and healthy, the mean temperature over 70° F., although it has fallen in severe winters to 22° below zero. Minerals are abundant, and include valuable beds of coal; and the manufactures and trade are of importance.—The capital, EKATERINOSLAV, on the Dnieper, 323 N. by E. of Sebastopol by rail, has a cathedral, a public library, a fine park, and large

tobacco factories. The town ('Catharine's Fame') was founded in 1784 by Prince Potemkin for the summer residence of the Empress Catharine II. Pop. 164,000.

Ekhmîm, or **IKHMÎM** (the ancient *Apu* or *Khemmis*, and called by the Greeks Panopolis), is a fair-sized town of Upper Egypt (pop. 15,000, chiefly Copts, but including Roman Catholics) on the east bank of the Nile near Suhâg, and was formerly the capital of the 9th nome of the south country (see EGYPT). Ruins mark the site of the temple of the local deity, Khim, the Egyptian Pan, but there are few remains of any importance. Herodotus speaks of Khemmis as a large city with a temple dedicated to Perseus, and it was still a leading place of the Thebaid in the days of Strabo; but the Arab conquest demolished the greater part. It was once famous for linen manufacture and masonry, and is still noted for its check cotton industry. Ekhmîm was the birthplace of Madame Blavatsky.

Ekowe, now **ESHOWE**. See **ZULUS**.

E Kron, the northernmost of the five great cities of the Philistines (q.v.), on the borders of Judah and Dan. Beelzebub (q.v.) was its god.

Elaeagnaceæ, a family of dicotyledons, of which there are about seventeen species, all natives of north temperate countries. *Elaeagnus angustifolia*, the so-called Oleaster, sometimes called Wild Olive, is a small spiny tree of the Mediterranean region, hoary with stellate hairs, and is frequently planted for the sake of its silvery-white foliage and its fragrant flowers. The Sea Buckthorn (q.v.), or Sallowthorn, is the only British species. The Silverberry, *Shepherdia argentea*, with pleasant fruit, and *S. canadensis*, have also been introduced to English parks from North America.

Elaeis. See **OIL, PALM**.

Elaeocarpaceæ, an order, or sub-order of Tiliaceæ, mostly East Indian trees. The fruits of some are eaten. The deeply wrinkled seeds or stones of the fruit of *Elaeocarpus ganitrus* are made into beads for necklaces and bracelets in India. They are often called Olive Nuts.

Elaeococca, a genus of Euphorbiaceæ, the seeds of some of which yield useful oils, that of *E. verrucosa* being used for food in Japan, and for burning in Mauritius. That of *E. vernicia* of China is used in painting.

Elaeodendron, a genus of Celastraceæ. *E. croceum* yields the useful Saffron-wood of the Cape.

Elaeabalus. See **HELOGABALUS**.

Elam, a district of ancient culture, lying south of Assyria and east of Persia proper, apparently the same as the Susiana of Strabo. Its chief city, Susa (*Shushan*), early attained great importance in Mesopotamia. It appears that the primitive Semitic Elamites were overcome at an early period by a Hamitic or Cushite race from Babylon, called by the Greeks Cossæans.

Eland (*Oreos canna*), an antelope of Central and South Africa, the largest of the group, which has sometimes bred in Britain. It is a plump, strong, ox-like animal, stands about six feet high at the shoulders, and has a predominantly light-brown colour, varying to reddish above and yellowish below. The horns, present in both sexes, are about a foot and a half long, straight or slightly bent, and bear a spiral keel. There is a marked dewlap on the throat of the bull, and a dark short mane from the forehead backwards. The tail is ox-like, and ends in a tuft of black hair. The eland lives in small herds, especially on the treeless flats; it can attain considerable speed, and must be hunted on horseback. It is locally known as the

Impoof or *Impoofoo*. The flesh is said to surpass beef, and the hide is also much valued. Once abundant all over South Africa, it is now restricted to the Kalahari Desert and a preserve in Natal. See **ANTELOPE**.

Elanet (*Elanus*), a genus of Falconidæ, including a number of kites, such as the Black-winged Kite (*E. caeruleus*) of Africa and India. Most of them feed on small prey, such as insects, snakes, and small mammals.

Elaphodus, a Chinese and Tibetan genus of deer, related to the muntjacs.

Elaphomyces, a genus of subterranean fungi of the truffle family.

Elaphure, or **PÈRE DAVID'S DEER** (*Cervus* or *Elaphurus davidianus*), a long-tailed deer kept in parks in China and now also elsewhere. The antler has no brow-tine.

Elaps. See **CORAL-SNAKE**.

El Araish (also called Laraisih, Larache), a fortified Atlantic seaport of Spanish Morocco, at the mouth of the Wad Lekkus, 45 miles SSW. of Tangier. The harbour, once a resort of the Sallî pirates, tends to silt up. The town has a citadel and other defences, a fine market-place, a mosque of some note, and a military railway to Alcazar. Its trade is extensive, especially in grain, beans, fruits, eggs, and wool. Ruins in the neighbourhood have been thought to be Phœnician. Pop. about 10,000.

El Arish, a fortified town of north-eastern Egypt, on the Mediterranean, at the mouth of the Wady-el-Arish, marks the boundary of Egypt and Palestine. It was taken by Kléber in 1799, and in 1916 was recaptured by the British from the Turks, who had seized it and made it their base. Pop. 20,000.

Elasmobranchii. See **CARTILAGINOUS FISHES**.

Elasmosaurians, gigantic marine saurians of the cretaceous period, whose remains have been found chiefly in New Jersey, United States. See **REPTILES**.

Elasticity is that property of matter which enables a body, whose form or bulk has been changed by force, to support without disintegration or further yielding the continued action of that force, and to recover its original form or bulk when left to itself. Any alteration in form or bulk of a body is called a strain, and the combination of forces producing the strain is called a stress. Now when an elastic body is strained, it becomes possessed of a certain power of doing work which it had not originally. As familiar examples of this we may mention the bent bow, the wound-up mainspring of a watch, and the compressed air of an air-gun. In these cases a certain amount of energy has to be spent to bring the substances into their strained condition. Then, on being allowed to recover themselves either suddenly or gradually by an appropriate withdrawal of the supporting stresses, these substances yield back, in the form of useful work, some of the energy originally expended. Again, in the phenomena of Sound (q.v.), we have constant illustrations of the elasticity of bodies. An elastic substance—a pianoforte string for example—is strained in a particular manner and then left to itself. It at once begins vibrating about its original position of equilibrium, the energy of strain being transformed into the energy of motion, and that again into the energy of strain, and so on until gradually it degenerates into heat under the influence of the viscosity of the air, the string itself, and whatever other elastic bodies may be in the vicinity.

Physically considered, sound is in fact a sub-section of elasticity. The power of conveying sound is possessed by all substances, whether solid or fluid; for such strains, then, all substances are truly elastic.

As regards fluids—i.e. gases and liquids, the only kind of elasticity that can exist is elasticity of bulk; for no portion of a fluid can sustain the action of a deforming force. Practically the only kind of stress we can apply to fluids so as to cause a change of volume is a pressure equal in all directions. It is found that at a given temperature, the volume of a given mass of fluid is determined by the pressure; so that, after being compressed by an increase of pressure, the fluid will recover its original volume when the pressure is brought back to its original value. Thus, all fluids are perfectly elastic. To discover how, under any circumstances, the pressure and volume are related to one another is clearly an elastic problem. Thus, we must regard Boyle's Law for gases, established by the Hon. R. Boyle (q.v.) for air in 1661, as the first experimental attempt to investigate the laws of elasticity (see GASES, and HYDRODYNAMICS). To the same class of problems belongs the determination of the compressibilities of liquids. Compression being defined as the diminution produced in unit volume of the substance by the application of a given extra pressure, compressibility is measured by the ratio of the compression to the related pressure, or, in more general language, by the ratio of the strain to the stress. Though considerable ranges of stress-values, this ratio is for most liquids constant. The reciprocal of the compressibility—i.e. the ratio of the appropriate stress and strain, is called the bulk-modulus of elasticity. It is the only modulus with which we have to do when the elasticity of fluids is being considered.

When we pass to the consideration of solids, we meet with another kind of elasticity, the elasticity of form. The resistance which a solid offers to a pure change of form, not involving a change of volume, is measured by its Rigidity (q.v.); and if for this change the body is truly elastic, the rigidity is measured by the ratio of the deforming stress to the resulting strain—i.e. it is the modulus of elasticity for this kind of stress and strain. A pure twist applied to a pillar, rod, or wire, is a strain which involves no change of volume. The resistance which such a pillar offers to torsion depends on its rigidity and form, but is independent of its compressibility. In most cases, however, when an elastic solid is strained by a particular kind of stress, the appropriate modulus of elasticity involves both the rigidity and the compressibility. Thus, when a wire is stretched by a longitudinal tension, it not only increases in length but also diminishes in section. The result is that any small cubical element becomes a brick-shaped portion somewhat greater in volume. It is usual to measure this kind of strain by the elongation simply, the contraction of the section being practically unimportant. The ratio of the tension to the elongation gives what is called Young's Modulus of Elasticity, a most important quantity in engineering. It is Young's modulus which also determines the resistance a beam or bar offers to bending. See STRENGTH OF MATERIALS.

The elasticity of solids is far from perfect—i.e. a very moderate stress well within the limits of rupture will produce a permanent set in the body, so that there will not be perfect recovery of form and dimensions when the stress is removed. It is difficult to fix accurately the so-called limits of perfect elasticity, since a small stress acting for a long time will produce a permanent set, which a much more powerful stress acting for a short time would not produce. So long, however, as the

strains are small, experiment shows that the stresses are proportional to the corresponding strains. In other words, the modulus of elasticity is constant through considerable ranges of stress-values. This empirical law was first clearly enunciated by Hooke in 1678 in the words *Ut Tensio sic Vis*; and upon a generalised statement of Hooke's Law the whole modern theory of elasticity is based.

See Lord Kelvin's article 'Elasticity' in the 9th ed. of *Encyclopædia Britannica* (republished in his *Math. and Phys. Papers*); Ibbetson's *Mathematical Theory of Elasticity* (1887); Love's *Mathematical Theory of Elasticity* (2d ed. 1906); and, for a valuable compendium and criticism of the labours of other elasticians, the *History of the Elasticity and Strength of Materials* (Cambridge University Press, 2 vols. 1886-9.), by Todhunter and Pearson, also the articles in this work on STRAIN, STRESS, STRENGTH OF MATERIALS, TORSION.

Elastic Tissue. See MUSCLE, TISSUE.

Elatér, a genus of beetles in the Pentamerous sub-order, type of the family Elateridæ. They are familiarly known as 'click-beetles' or 'skip-jacks,' from their habit of jerking themselves with a slight noise into the air when they land or are placed on their backs. The body is arched upwards and suddenly straightened with a violent muscular exertion, which lifts the animal from the ground. The legs are too short for the ordinary method of righting the body. For the larvæ, see WIREWORMS; for phosphorescent, FIREFLIES. For elaters in botany, see HORSETAIL, LIVERWORTS.

Elaterrite. See BITUMEN.

Elatarium, a drug obtained from the fruit of the Squirting Cucumber (*Ecballium Elaterium*, formerly *Momordica Elaterium*), a native of the south of Europe, common on rubbish in the villages of Greece and the Archipelago.

The fruit breaks from its stalk, and violently expels its seeds with the surrounding mucus through the opening thus made. This remarkable phenomenon is not due to any true contractility, but simply to the tension due to osmosis; much, in fact, as ripe gooseberries burst after prolonged rainy weather. It is the thick green mucus surrounding the seeds which yields the elaterium. This is simply prepared by drying the sediment from the juice pressed from the newly ripened fruit.

Elatarium is a drastic hydragogue cathartic. Its active principle is a body called Elaterin, $C_{20}H_{28}O_8$, which is probably the most powerful purgative known, the ordinary dose being only from $\frac{1}{16}$ to $\frac{1}{8}$ grain. It is an exceedingly drastic purgative, used in dropsy. It acts as an irritant not only on the eyes, but even on the fingers of those who handle it. The use of elaterium was known to the ancients.

Elath. See AKABAH.

Elatma. See JELATOM.

El Azariyeh. See BETHANY.

Elba (Gr. *Aithalia*, Lat. *Iva*), an island belonging to Italy, in the Mediterranean Sea, between

Squirting Cucumber
(*Ecballium Elaterium*).

Corsica and the coast of Tuscany, from the latter of which it is separated by the channel of Piombino, a strait 6 miles in breadth. Area, 85 sq. m. The coast is bold and precipitous, the interior traversed nearly throughout by three mountain-ranges which reach a height of 3380 feet. The island is well watered, the climate mild and healthy; on the lower ridges of the mountains, and in the valleys, the vine, olive, and mulberry flourish, fenced in with hedges of cactus and agave. The chief industry is the mining of the rich iron ore, for which Elba has been famed from antiquity; serpentine and chalk, granite and marble also are quarried, while some salt is produced from the salt-pans along the coast. Much wine is made, and the tunny-fisheries are important. Porto Ferrajo, the capital, has a pop. of 12,000. Elba has been rendered famous in history as Napoleon's kingdom in exile from May 1814 till February 1815.

El Bassan, a town of central Albania, 75 miles SSE. of Scutari, with manufactures of copper and iron wares. It is the capital of a prefecture. Pop. 10,000.

Elbe (the Roman *Albis* and the Bohemian *Laabe*), an important river of northern Europe. It originates in the confluence of numerous streams which rise on the southern side of the Riesengebirge or Giant's Mountains, a range on the northern border of Bohemia, and unite near 50° 46' N. lat., 15° 32' E. long., at an elevation of 2230 feet above sea-level. Its total length, including windings, is estimated at 725 miles; it is navigable for 525 miles, as far as Melnik, but for sea-vessels only up to Hamburg (84 miles); and it drains an area of over 55,000 sq. m., of which two-thirds is German territory. Of its fifty and more tributaries the most important are the Moldau, Eger, Mulde, Saale, and Havel (with the Spree); and in connection with these is a fine system of canals. From the base of the Schneekoppe, the Elbe flows south to Pardubitz, whence it proceeds west to Brandeis, and afterwards in a general north-west direction past Melnik, Leitmeritz, and Herrnskretsch, where it quits the Bohemian territory and enters Saxony. At this point it is 142 yards wide. It then meanders, in a generally north-westerly course, through Saxony, Anhalt, and Hanover, passing Pirna, Dresden, Meissen, Torgau, Wittenberg, Magdeburg, Harburg, and Hamburg, until it empties itself into the North Sea at Cuxhaven, where it attains a breadth of upwards of 10 miles. The estuary is defended by five forts. At this point the tide rises about 10 feet; it is perceptible over 100 miles up the river. The Elbe is divided into several branches between Hamburg on the north, and Harburg on the south, by the numerous islands that there interrupt its course; and between Hamburg and the sea the sandbanks and shoals leave only a very narrow channel, of four to five fathoms' depth, and carefully marked. The scenery of the valley of the Elbe, although generally pleasing, is not remarkable, except in the Saxon Switzerland, above Dresden, where the river's course is generally between fantastic sandstone cliffs. Its waters are stocked with abundance of highly esteemed fish. Steamboats ply from Dresden up the river to Melnik, and down as far as Riesa, as well as from Magdeburg to the sea. The navigation of the Elbe was formerly impeded by all manner of imposts and monopolies, but in 1870 all then existing tolls were abolished.

Elberfeld, one of the manufacturing capitals of Germany, is situated on both sides of the Wupper, an affluent of the Rhine, 16 miles ENE. of Düsseldorf. The old parts of the town are poorly built, straggling, and irregular, but the newer portion has numerous spacious and imposing build-

ings. The town is famous for its dyeing, bleaching, and calico-printing, also for its manufactures of cottons, woollens, silks, ribbons, thread, lace, buttons, machinery, iron and steel wares, pianofortes, paper, and carpets. Close by is Barmen (q.v.). The Wupper valley has long been noted for its interest in religious work, in missions and Bible societies; and since 1852 Elberfeld has had a singularly effective method of voluntary but systematic poor-relief, devised by the banker, Daniel von der Heydt. The city is divided into over 360 districts, each under an (unpaid) almoner; and the almoners, under a superintendent, form a committee which meets fortnightly to discuss cases and vote relief. The work is under the direction of a board comprising the mayor, four councillors, and four elected citizens. Relief is granted according to a scheduled rate for two weeks at a time; but every case is considered on its merits. Family earnings are taken into consideration, and tools may be provided. The system, though all its representatives are unpaid, is thoroughly organised, energetic, and efficient. The condition of the poor has improved; and whereas in 1855 17 per 1000 required assistance, only 7 or 8 were necessitous at the close of the century. The Elberfeld system has been introduced or partially imitated in many German and Austrian towns. See Julie Sutter, *Britain's Next Campaign* (1901). Pop. (1875) 30,599; (1910) 170,195; (1919) 157,218.

Elbeuf, a town of Seine-Inférieure, on the left bank of the Seine, 14 miles S. by W. of Rouen; pop. 20,000. The manufactures of cloths, flannels, billiard-cloths, and light woollens employ some 25,000 men here and in the neighbouring towns.

Elbing, a town of West Prussia, 48 miles ESE. of Danzig, on the navigable Elbing, which enters the Frisches Haff 5 miles to the north. The town, founded in the 13th century, is connected by canal with a tributary of the Vistula. Ships are built; and there are iron and brass rolling-mills, and tin-ware and cigar factories. Pop. (1875) 33,572; (1919) 67,127.

Elbow. See ARM.

Elburz, a mountain-range of Persia, running for 450 miles along the southern border of the Caspian Sea. It frequently divides itself into subordinate parallel ridges, enclosing extensive and fertile valleys; and unlike most Persian ranges, it has numerous prominent spurs, the highest peak being Mount Demavend (q.v.).—**ELBURZ** is also the name of the loftiest summit of the Caucasus (q.v.).

Elché, a town of Spain, 13 miles SW. of Alicante by rail, fringed by an encircling grove of nearly 100,000 palms, which gives the place an appearance half Moorish. It has a fine collegiate church, with a lofty tiled dome, and some trade in esparto, wine, dates, and palm-branches. Pop. 33,000.

Elchingen, a village of Bavaria, near the Danube, 5 miles NE. of Ulm, where on 14th October 1805 Ney defeated the Austrians under Laudon, winning thereby the title of Duke of Elchingen.

Elcho, LORD. See WEMYSS.

Elder (*Sambucus*), a genus of plants of the natural order Caprifoliaceæ, sub-order Sambuceæ, consisting chiefly of shrubs and trees, with pinnate leaves, small flowers of which the corolla is wheel-shaped and 5-cleft, and 3-seeded berries. The species are very widely distributed.—The Common Elder (*S. nigra*), the *Bourtree* of the Scotch, is a native of Europe, the north of Asia, and the north of Africa. It is found in all parts of Britain. It is a very large shrub, sometimes a small tree, with rather large leaves, and large terminal cymes of cream-coloured flowers, which are followed by small black—or rarely whitish—berries.

Its leaves and young shoots diffuse a narcotic odour, and it is said to be dangerous to sleep under its shade. The young leaf-buds are so violently purgative as to be considered dangerous. The inner bark has a bitter acrid taste. The leaves possess the

Flowering branch of Common Elder (*Sambucus nigra*):
a, a flower; b, berries

same properties in a rather milder degree. The flowers have a peculiar sweetish and rather sickening smell, but are used for making a distilled water—*Elder Flower Water*—which has a very agreeable odour, and is employed both in perfumery and confectionery. Distilled with water alone, they yield a volatile oil, which, on cooling, assumes a buttery consistence. A popular cooling ointment is made by boiling them in lard. They are also used for imparting a flavour to currant-wine and jelly. The clustered flower-buds are pickled, and used like capers. The French put layers of them in heaps or casks of apples, to which they impart an agreeable odour. A grateful wine, well known in England, especially about Christmas, is made from the berries; and in some places there are plantations of elder to supply the London market. It is generally drunk hot or *mulled*. The berries are subacid and sweetish, with an unpleasant flavour; but a rob or syrup made from them is an agreeable domestic remedy with country-people for colds, coughs, and sore throats, and is slightly purgative; it has some reputation also in a concentrated form as a cure in rheumatic, gouty, eruptive, and syphilitic disorders. In some parts of Germany the poorer people use them as an ingredient in soups. They are said to be used to no small extent in England in the adulteration of port wine and the manufacture of spurious port wine.—The wood of the elder is yellow; that of old trees is very hard and tough, takes a fine polish, is used by turners, and as a substitute for boxwood in making mathematical instruments and other articles. Tops of fishing-rods are sometimes made of it. The pith of the young shoots being very light, is generally used to make pith-balls for electrical experiments. Toys for children are also made of it; and few boys are unacquainted with the use of elder branches, from which it has been expelled, for making popguns. A musical instrument named by the Latins *sambuca* is supposed to have been made from the wood of this tree on account of its hardness. The elder is very useful as a screen-fence near the sea and in other exposed situations, as it grows with remarkable vigour, and makes great shoots, the destruction of the more tender and less matured parts of which in winter only tends to make it more bushy and useful for shelter. It is

readily propagated by portions of its shoots stuck into the ground.—The Scarlet-fruited Elder (*S. racemosa*), a native of the south of Europe and of Siberia, much resembles the common elder, but has softer and more herbaceous shoots, remarkably large buds, and racemes of greenish-white flowers, which are followed by scarlet berries. It is a frequent ornament of shrubberies in Britain.—The Dwarf Elder, or Danewort (*S. Ebulus*), is a rather rare British plant, a coarse herbaceous plant, with fetid smell. The *inner bark* has been employed in diopical complaints as a hydragogue cathartic. The leaves are avoided by cattle, moles will not come near any place in which they are laid, and they are said to drive mice and rats from granaries if stewed plentifully about their haunts for a time. *White elder ointment* is procured by boiling equal weights of lard and elder flowers, and pressing through a cloth.—*S. canadensis* and *S. pubens* are North American species; the former, which is the common American kind, much resembles *S. nigra*, and the latter in like manner approaches *S. racemosa*. Larger than either are the *S. glauca* of the Pacific states, and the *S. mexicana* of the south-west.

The elder is very prominent in European folklore, and innumerable superstitions cling to the tree, its twigs and leaves. The cross was reported to have been made of this wood. Judas was said to have hanged himself on an elder-tree; lightning will not strike an elder; twigs growing from the edge of decayed hollows in an old elder will ward off teething fits from children; in Denmark a spirit called the Elder-mother protects the tree and avenges injuries offered to it; warts are removed by being rubbed with elder twig; and, generally, the tree or a twig of it protects against witches and witchcraft.

Elder, an office-bearer in Presbyterian churches. The name is an exact translation of the Greek *presbyteros*, which occurs frequently in the New Testament, and from which the English word *priest* is derived; but there remains much division of opinion as to the precise meaning of the term (see BISHOP, INDEPENDENTS, and PRESBYTERIANISM). All are agreed indeed that *bishops* and all pastors of congregations are included among *elders* in the scriptural use of the term; but the ordinary use of it is now limited to Presbyterian churches, and in them it has become the usual designation of the office-bearers associated with the minister of each congregation in the care and oversight of the flock. In some Protestant churches elders are appointed only for a certain term of office; but more generally it is until death, resignation, removal from the bounds of the congregation, or deposition. The appointment of elders takes place variously; in the Established Church of Scotland they have generally been nominated by the kirk-session (consisting of the minister and elders); in the other Presbyterian churches of Britain and America they are elected by the congregation. The ordination of elders takes place in the congregation, but usually without imposition of hands; a difference between the mode of ordination of elders and ministers for which it is not easy to account, and which has certainly tended to produce a general impression that a greater difference of office subsists than the advocates of Presbyterianism admit. In the Established Church of Scotland, the elders have very generally discharged also the functions of Deacons (q.v.). According to the *Second Book of Discipline* of the Church of Scotland, it is the duty of elders to watch over the spiritual welfare of the people, to admonish, to visit the sick, to assist in the examination of persons seeking admission to the Lord's Table, &c. Elders along with ministers compose all the courts or assemblies of the Presbyterian churches, and have equal votes in all questions.

Eldon, LORD, Lord Chancellor. John Scott, better known as Lord Eldon, was born 4th June 1751, in Love Lane, Newcastle, of obscure but respectable parentage. Lord Stowell (q.v.) was his elder brother. Leaving the Newcastle grammar-school in 1766, John Scott entered University College, Oxford, with a view to the church, and the following year he obtained a fellowship. A run-away marriage, into which he entered with a Miss Surtees in 1772, nearly ruined him; however, by the advice of his brother, he returned with his wife to the university. Here, during the year of grace after his marriage, he lived on his fellowship and gains as a private tutor; and the year expiring without a college living falling vacant, he betook himself to the study of law. In 1776 he was called to the bar. By the death of his father, in the year of his call, Eldon found himself in possession of £3000. Success soon dawned on him; and, with success in his profession, his ambition expanded, he took to politics. A silk gown and a seat in parliament were but steps towards knighthood and the post of Solicitor-general, conferred on him by Pitt in 1788. In 1793 he became Attorney-general. In 1799 the office of Chief-justice of the Court of Common Pleas became his, as Baron Eldon; and in 1801 he ascended the woolsack. From this time till 1827, with little intermission, Eldon continued to occupy the woolsack under successive governments. In 1821 he had been made an earl by George IV. In 1834 he ceased to speak in parliament. After outliving almost all his immediate relations, he died in his eighty-seventh year, January 13, 1838, leaving behind him a fortune of over half a million sterling.

Eldon was a handsome man, of very winning and courtly manners. His career amply proves that he had the greatest talent, sagacity, and power of managing men. He was undoubtedly a great lawyer, and his judgments, which have been much praised for their accuracy, fill a small library; but he took so long to arrive at them, that he has been charged with having caused more injustice by delay than worse judges by the iniquity of their decisions. For literature, as for art, he had no feeling, and the style of his decisions is generally detestable. As a public speaker he is far from estimable. He was no statesman; for forty years he was a leading enemy of reform and religious liberty, and it may be said that his whole political stock in trade was zeal against the Roman Catholics. He is said to have added parsimony to his other defects; but it is certain he was capable of generous actions, and his devotion to 'Bessy' his wife was truly beautiful. See the Life by Twiss (1846), and Campbell's *Lives of the Chancellors*.

El Dorado ('the Gilded Man'—afterwards transferred to a city or land) existed vaguely in the imaginations of the Spanish conquerors of America, whose avarice, feeding greedily on the marvellous accounts readily supplied by the natives—who were only anxious to get rid of their robber-guests—loved to dream of richer rewards than those of Mexico and Peru. But after Orrellana's voyage down the Amazon, in 1540, the report was greatly embellished, and the locality of the fabulous region placed near the head-springs of the Orinoco. Many a soldier of fortune perished in the search, many a brave troop of adventurers brought but a fraction of their number back, before Manoa, the city of gold, was reluctantly relegated to the atlas of the poets, with the fabled king who, smeared with gold-dust, bathed annually in the sacred lake. Sir Walter Raleigh was one of those who sought in vain.

See Nery, *Le Pays des Amazones* (Paris, 1885); Von Langegg, *El Dorado* (1888); Bandler, *The Gilded King* (N. Y. 1893); Petrie, *The Republic of Colombia* (1906).

Elæatic School. The group of ancient Greek philosophers so called begins with Xenophanes of Colophon, who settled in Elea, a Greek city of Lower Italy (whence the name), and includes Parmenides and Zeno, who both belonged to Elea, and also Melissus of Samos. In opposition to the physical philosophy of the Ionic school, and to the doctrine of Heraclitus (q.v.), who denied all being or existence, the Eleatic philosophers made the conception of pure being, unmixed with all marks or properties derived through the senses, the foundation of all their speculations. They argued the unity and immutability of all things, and, attacking the prevalent anthropomorphic mythology, they taught that God is the One, self-existent, unchangeable, and incomparable in any respect to man. Moreover, distrusting all knowledge acquired through the senses, they held that it is by thought only that we arrive at the truth; and Zeno's most subtle paradoxes were directed to prove this opposition between thought and sense. See separate articles on the principal philosophers mentioned.

Elecampane (*Inula*), a genus of Compositæ, allied to *Aster*. The only important species is the common Elecampane (*I. Helenium*),

a native of damp meadows in the middle and south of Europe, rather rare in Britain, but not uncommon in the long-settled parts of North America. This plant was formerly much cultivated for its medicinal root, but is now comparatively neglected. The flowers are sometimes used to adulterate arnica.

Elecampane (Inula Helenium):
a, flower.

Election, in Law, sometimes denotes the act of choosing, and sometimes the right of choosing. By the equitable doctrine of election in English law, one who accepts a benefit under an instrument, such as a deed or will, must adopt the whole deed, and conform with all its provisions. He is not entitled to take benefit under part of the deed without conforming to its other parts, and renouncing rights inconsistent with them. He must 'make his election' between the provisions of the deed and those of the common law. The analogous doctrine in the law of Scotland is that of Approbate and Reprobate (q.v.).

Election denotes in theological language the divine act by which certain individuals are chosen to salvation in Christ. It is defined in the seventeenth of the Thirty-nine Articles. See PRE-DESTINATION.

Election. See PARLIAMENT, and REPRESENTATION.

Electors (Ger. *Kurfürsten*), in the German empire, were those great princes who had the right of electing the emperor or king. In the earliest times, under the Carolingians, the crown was

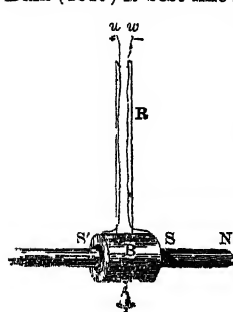

hereditary; afterwards Germany became formally an elective monarchy, but the election was practically almost limited to the reigning family. In the 13th century the right of election, for a time exercised by all the princes of the empire, became limited to the holders of the highest ecclesiastical and civil offices, some of which gradually became hereditary, and connected with territorial principalities, as in the case of the Hohenstaufens and of the Dukes of Bavaria, Saxony, Swabia, &c. Thus, there came to be seven electors, the spiritual electors of Mainz, Treves, and Cologne (as being the three chancellors of the empire), the elector of the Palatinate (as imperial steward), of Brandenburg (as chamberlain), Saxony (marshal), and Bohemia (imperial cup-bearer). During the Thirty Years' War, the right of the Palatinate was conferred on Bavaria; by the peace of Westphalia, an eighth electorate was established, Bavaria and the Palatinate being each allowed the full right; and in 1692 a ninth was added, that of Brunswick-Luneburg (Hanover), but not without resistance by the electors and states of the empire, so that the new electorate was not fully recognised till 1710. In 1777 the number was again reduced to eight, the Bavarian electorate falling to the Elector Palatine. The electors held a very lofty position in the German empire. The Golden Bull (1356) describes them as 'the seven pillars and lamps of the holy empire.' They had many important rights, exemptions, and privileges, and royal dignity (but not the title of Majesty).

During the French ascendancy great changes took place. Of the old electorates only that of Mainz was left, but three new ones—Baden, Württemberg, and Hesse-Cassel—and later one of Salzburg, were created. With the dissolution of the German empire the dignity of elector vanished, but the empty title continued to be used by the elector of Hesse-Cassel till 1866. See GERMANY.

Electra, daughter of Agamemnon and Clytemnestra, sister of Iphigenia and Orestes. After her father's murder by her mother, she saved the life of the young Orestes, and sent him to King Strophius to be brought up; and then helped him to avenge Agamemnon's death by slaying Clytemnestra. She was given in marriage by Orestes to his friend Pylades. Her story, treated also by Æschylus and Euripides, is the subject of a splendid tragedy by Sophocles; and Hofmannsthal's adaptation was the basis of the opera by R. Strauss (1909).

Electric Bells. See BELL.

Electric Clocks are either those in which the impulse is given to the pendulum directly by electric power, or those in which it is given by a weight or spring alternately liberated and restrained by electricity. Of the first kind, that invented by Bain (1840) is best known. In the ordinary clock,

low in the centre; the wires *u, w* from both ends run along each side of the pendulum rod, *R* (the

lower part of which alone is seen), and are in metallic connection respectively with the two springs from which the pendulum hangs. Two magnets or bundles of magnetic rods, *NS, N'S'*, are fixed at either side of the bob, and are of such dimensions that the hollow bob in its oscillation can pass a certain way over each without touching. The magnets have their like poles turned towards each other. The two springs of the pendulum rod are in connection with the two poles of a galvanic battery. In the connection between one of these springs and the battery there is a break (not shown in the figure) worked by the pendulum rod. When the pendulum is made to move, say, towards the right, it shifts a slider, so as to complete the connection between the poles of the battery. The current thereupon descends one of the wires of the pendulum, passes through the coil of wire forming the bob, and ascends by the other. In so doing, it converts the bob into a temporary magnet, the south pole towards the right, and the north pole towards the left. In this way, the south pole of the bob is repelled by the south pole, *S*, of the right-hand magnet; and its north pole is attracted by the south pole, *S'*, of the left-hand magnet, so that from this double repulsion and attraction both acting in the same direction, the bob receives an impulse towards the left. Partly, therefore, from this impulse, and partly from its own weight, the pendulum describes its left oscillation; and when it reaches the end of it, it moves the slider so as to cut off the battery current, and then returns towards the right, under the action simply of its own weight. On reaching the extreme right, as before, it receives a fresh impulse; and thus, under the electric force exerted during its left oscillation, the motion of the pendulum is maintained. So long as the electricity is supplied the pendulum will continue to move. The current required is exceedingly weak.

A very important application of Bain's pendulum was made by Jones of Chester (1857). Shortly after the invention of Bain's clock, Professor Wheatstone suggested that any number of such clocks could be made to move simultaneously by the same current of electricity. Jones turned this idea to account in the following way. A standard clock of the usual construction is made, by regulating the flow of a galvanic current, to control the action of any number of copying clocks, likewise of ordinary construction. The pendulum of the standard clock, itself in no way under electric control, on passing towards the right, touches a spring placed at the side, thereby completing the battery connection, and a current is transmitted to the copying clocks in a certain direction. On passing to the left side, the same takes place, but the current this time is sent through the circuit in the opposite direction. The pendulums of the copying clocks are made on Bain's principle, but have, of course, no break to move, as the primary pendulum performs that function. Let us suppose, at first, that all the pendulums are at rest; in this case no current is transmitted. Let the standard pendulum now be moved to the right, the right spring is touched, and a current at the same instant circulates through the bobs of the copying pendulums, and they thereby receive a simultaneous impulse towards the left. All the pendulums move then to the left; and on reaching the extremity of this oscillation, the standard pendulum touches the left spring, and the secondary pendulums are now impelled to the right. The motion of each secondary pendulum soon increases, until it reaches its proper extent. The pendulums once set a-going are, however, not intrusted solely to the stimulus of the electricity, but are moved by their own weights, as in ordinary clocks, so that if the electricity ceased to be sent to them, they would go on without it.

In the second class of electric clocks, the electricity is not charged immediately with the maintaining of the pendulum motion, but draws up the weight, or liberates the spring which discharges that function. This is the same principle as holds in what is known in horology as the 'remontoir' escapement. Ritchie of Edinburgh successfully combined the principles of Bain's and Jones's clocks, effecting the almost perfect control, by one standard clock, of a number of subordinate others. The pendulums of these controlled clocks vibrate by electro-magnetic action alone, and they consequently require no winding up.

Mr A. Stenart (*Proc. Roy. Soc. Edin.* xliii. 1923) describes a clock in which the electric motor that drives the hands (and a telescope or chronograph drum if desired) also raises a gravity arm, which descending acts on the pendulum. It is then arrested, and electric power passes to the motor while arm and stop are in contact. The current is interrupted when the motor raises the arm. The speed of the motor is governed by the time of contact, but its motion is maintained between contacts by a reduced current and by kinetic energy.

Electric Fishes. Electric organs are found in a few fishes; peculiar structures arising from a modification of muscular tissue, and capable under nervous control of a genuine electric discharge. The degrees of development vary greatly. The organs are powerful in the Electric Eel (*Gymnotus*), in the African Cat-fish (*Malapterurus*), and in the Electric Ray (*Torpedo*), in order of merit. They are weakly developed, or 'pseudo-electric,' as they used to be called, in all the Rays except *Torpedo*, and in several species of bony fishes (*Mormyrus* and *Gymnarchus*). Professor Cossar Ewart has demonstrated a very rudimentary electric organ in the common skate.

Structure.—It may now be regarded as demonstrated that all these electric organs are modified muscle-tracts. The associated nerve-endings are comparable to the ordinary terminations of a motor nerve on a muscle. The organs consist of a large number of rounded chambers or prismatic columns, separated by longitudinal and transverse partitions of fibrous connective tissue. In these partitions there are blood-vessels and nerves with very thick sheaths. The nerves lose their thickness, branch greatly, and finally fuse with 'electric plates,' or discs of modified muscular substance. Besides the essential electric plate, the compartment may contain a jelly-like substance or a fluid. Partitions, nerves, and the 'electric plate' form in all cases the principal structures.

Arrangement.—The electric organs not only occur in a well-developed state in three very widely separated fishes, but the arrangement in each case is different. (a) In the *Gymnotus*, which is abundant in the fresh water of Brazil and the Guianas, they replace the lower muscles along the sides of the tail. This is also the position of the weakly developed organs in the Rays (except *Torpedo*) and in the bony fishes already mentioned.

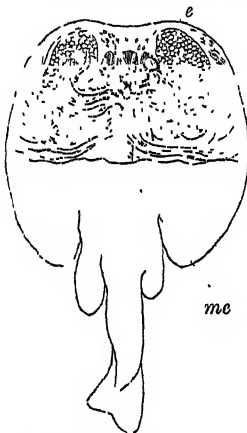

Fig. 1.—Electrical Apparatus of *Torpedo* (dissected): e, electric organs; me, spinal cord.

As *Gymnotus* may measure 6 feet in length, and has a very long tail, there is little wonder that its electric discharge is emphatically dangerous. The whole apparatus is supplied with more than 200 spinal nerves; one inch in length contains over 200 chambers (Gunther).

(b) In the African cat-fish, which is not uncommon in tropical Africa, and is represented by *M. electricus* in the Nile, the organ is more diffuse. It forms a sheath almost round the body, lying between the skin and muscles, but is thickest along the lower sides. The innervation is remarkable, for there is but one enormous nerve for each side. This arises from a giant cell high up on the spinal cord, and distributes branches throughout the body. The fish is again very long, measuring about 4 feet, and ranks second in the series. (c) In the Electric Rays (*Torpedo*), which occur in the Atlantic and Indian oceans and in the Mediterranean, the organs are broad, bounded by the gills, the pectoral fins, and the head. The prisms, of which there are many hundreds in each battery, lie vertically, not longitudinally as in the two preceding cases; and the nerves, instead of coming from the spinal cord, arise directly from the brain. Four of the five principal nerves on each side 'are each as thick as the spinal cord.' It is noteworthy that the above electric fishes have all smooth skins.

Function.—How the 'electric plates' come to be charged with electricity is not yet elucidated. The currents have all the usual characteristics of electricity: 'they render the needle magnetic, decompose chemical compounds, and emit the spark' (Gunther). 'The side of the electric plate on which the nerve branches out is negative at the moment of discharge, while the opposite side is positive, and from the different arrangements of the parts the electric shock passes in different directions in the three fishes—in *Malapterurus* from the head to the tail, in *Gymnotus* in the contrary direction, in *Torpedo* from below upwards' (Wiedersheim and Parker). The activity of the organ is wholly dependent (a) upon nerve stimulus from the brain, and (b) upon a certain degree of freshness in the structure itself. If the connection with the brain be severed, no discharge can be produced, except of course by the artificial stimulus of the severed nerves. Or if numerous rapidly repeated discharges have been already evoked, the organ is exhausted, and requires rest and recuperation before it becomes again functional. Humboldt's graphic story of the capture of electric eels by letting them first exhaust themselves in attacking horses has never been confirmed. In natural life the strength of the shock varies with the degree of development reached by the organ, with the size, health, and humour of the fish, and with the amount of reserve energy within the structure. A ray measuring 2 to 3 feet in width is 'able to disable by a single discharge a full-grown man,' and yet the ray is the least powerful of the three. To receive the shock the

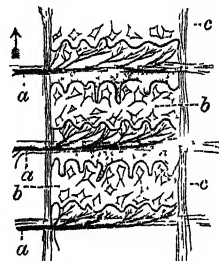

Fig. 2.—Section through Electric Chambers (greatly enlarged and semi-diagrammatic, from Wiedersheim and Parker): a, nerve branching up into fibres; b, electric plates; c, connective-tissue walls of compartments.

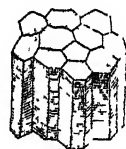

Fig. 3.—Electric Prisms of *Torpedo*.

object must complete the circuit by a double contact with the fish either directly or through some intervening substance. When well developed, the organ may be useful to the fish in two ways—in paralysing or killing other fishes used as food, and in warding off the attacks of enemies.

The electric ray and eel were known to the ancients, and were used for curative purposes, 'the earliest electric machines employed by mankind.' Scientific research on the electric organs really began with Walsh's demonstration (1772) of the genuinely electrical character of the discharge. The subject has been much worked at by some of the ablest anatomists and physiologists, and certainly is not yet finished. The origin of the organs, useless when incipient, and the connection between this peculiar development and the ordinary electrical properties of muscle and nerve are unsolved problems.

See MUSCLE, NERVOUS SYSTEM; Gunther's *Introd. to the Study of Fishes* (1880); and the works on comparative anatomy by Gegenbaur (trans. 1878) and Wiedersheim (1897). The best recent account of the production of electricity by living creatures is by S. Garten in Winterstein's great *Handbuch der Vergleichenden Physiologie* (Jena, 1910-14).

Electric Furnace, an apparatus consisting mainly of two carbon poles meeting in a crucible, and connected with a suitably powerful electric current. The electric furnace is capable of producing prodigious heat, and of reducing otherwise very intractable substances.

Electricity.* If a stick of sealing-wax is rubbed vigorously with woollen cloth it will be found capable of attracting small shreds of paper. This is the simplest experiment in electricity. Many other substances, such as resin, vulcanite, glass, &c., can be made to show the same phenomenon. To obtain the best effect with any given substance, a particular rubber must be chosen. For example, a cat's fur, slightly warmed, is very efficient in electrifying vulcanite or resin; while silk, amongst simple substances, should be used to excite glass. It is now known, however, that any two different substances, which can be rubbed together, become electrified by the friction. Thus, if wax and glass are rubbed together, they will both become electrified—i.e. capable of attracting light objects. And so, in the other instances, it can be shown by experiment that the cloth is electrified as well as the wax, the cat's fur as well as the vulcanite, the silk as well as the glass. Moreover, the two substances so electrified by mutual rubbing are found to attract one another, being indeed *oppositely* electrified—a term which the following experiment will elucidate.

Let two pieces of glass be electrified by rubbing each with a distinct piece of resin. The pieces of resin will also be electrified, and it will be found (1) that the pieces of glass repel each other; (2) that the pieces of resin repel each other; (3) that each piece of glass attracts each piece of resin. Exactly the same phenomena of attraction and repulsion will be shown—only much more powerfully because of the greater efficiency of the rubbing—if the pieces of resin are rubbed with cat's fur and the pieces of glass with silk.

Again, let a small light body, a pith-ball for example, be suspended at the end of a silk thread. This will be attracted by either the resin or the glass. But if it is allowed to come into contact with, say, the resin, it will immediately be repelled by the resin and strongly attracted by the glass. And if it should be allowed to touch the glass, it will thereafter be repelled by the glass and strongly attracted by the resin. By such contact the pith-ball itself becomes electrified; for it will repel a

second pith-ball similarly treated. We are thus led to the following conclusions. Repulsion exists between bodies which are similarly electrified, and attraction between bodies which are oppositely electrified. Bodies, electrified by mutual rubbing, become oppositely electrified. A body, electrified by contact with an electrified body, becomes electrified similarly to that body. Substances which like silk-rubbed glass repel silk-rubbed glass and attract wool rubbed resin are vitreously or *positively* electrified, while bodies which attract silk-rubbed glass and repel wool-rubbed resin are resinously or *negatively* electrified. The indication of the two kinds of electrification by opposite signs is very appropriate, but the application of the positive sign to one rather than to the other is a matter of convention and purely arbitrary.

To study electrical phenomena by means of metallic substances, it is necessary first of all to *insulate* them—i.e. to support them on glass, vulcanite, paraffin, &c., or to hang them by silk threads. The significance of the term insulation will appear from the following experiment. Hang two metal balls, one by a silk thread and the other by a wire, and touch them with a piece of wax strongly electrified by friction. On trial, the silk-suspended ball will be found electrified; but not so the wire-suspended ball. Thus we recognise two kinds of substances—viz. *insulators* and *non-insulators*. The latter are usually called *conductors*, and include all ordinary metals. Such conductors can be made to show electrification only when they are insulated.

When a body is sufficiently strongly electrified and brought very near another body originally un-electrified, a spark will pass between them even before they are made to touch. If this second body is the finger or knuckle, the spark will be accompanied by a peculiar sensation called an electric shock. Now let us take such a highly electrified conductor A, and bring pretty near to it a second insulated conductor B, but not so near as to cause a spark to pass. If, then, the finger be brought near enough to B a shock will be felt, a spark will pass between B and the finger, although B was originally not electrified. Thus B has become electrified by being brought into the neighbourhood of A. This mode of electrification is called electrification by *induction*. As Faraday clearly pointed out, it 'has the character of a first, essential, and fundamental principle,' and its thorough comprehension is of prime importance.

As it is our purpose to regard the whole subject from the Faraday point of view, it will be convenient to define certain useful terms. The *electric field* is any region of air, glass, vulcanite, or other non-conducting substance surrounding or containing electrified bodies. In it and through it the electric forces act; hence it is convenient to call such insulating substances *dielectrics*. To investigate the properties of an electric field it is generally necessary to bring into it a conductor, as in the experiment just described. In that experiment the induced electrical condition of B was studied by means of physiological sensation, partly optical, partly muscular. A far better way, however, of studying the phenomena of induction is to make use of the fundamental laws of attraction and repulsion between electrified bodies, as they are mechanically applied in such instruments as the gold-leaf electroscope, Coulomb's torsion balance, Thomson's (Kelvin's) quadrant electrometer, &c.

In the gold-leaf electroscope (invented by Bennet

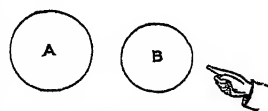

Fig. 1.

*The word *electric* was coined by William Gilbert. See AMBER.
173

in 1787), two light strips of gold-leaf hang from the lower end of a metal rod, which passes vertically through an opening in the top of a glass bottle and expands above into a plate. If a piece of rubbed sealing-wax or other electrified body be brought near the plate, the gold-leaves will repel each other and diverge. In other words, the conductor, consisting of the plate, rod, and gold-leaves, has been introduced into an electric field, and has in consequence become electrified by induction. This is shown by the repulsion between the similarly electrified gold-leaves. The nearer the electrified body is brought, the stronger is the electric field surrounding the electroscope, the wider do the gold-

leaves diverge. Here evidently the repulsion tends to lift the centre of gravity of each gold-leaf, and is finally balanced by the action of gravity. A cylinder of wire gauze, placed just inside the glass case, improves the action of the instrument. In another form of gold-leaf electroscope there is only one gold-leaf, the place of the other gold-leaf being taken by the continuation downwards of the rod to which the gold-leaf is attached. On electrification the single gold-leaf is repelled outwards from the rod towards another conductor which is kept in connection with the earth. Many sensitive forms of this type of electroscope have been

Fig. 2.

constructed within recent years for the study of radio-activity and ionisation. The position of the gold-leaf, projected against a micrometer scale, can be measured with great accuracy, and quantitative results obtained with remarkable ease.

In Coulomb's torsion balance the force with which one small charged sphere is repelled by another similarly charged is balanced by the torsion of a wire, which acts as suspension to a horizontal insulating rod bearing the one sphere at one of its ends. By means of this apparatus Coulomb showed, in 1785, that two small charged balls repelled each other with a force which diminished as the square of the distance increased. By assuming that the force between two charges, e , e' , on two small spheres is measured by the expression ee'/r^2 , where r is the distance between the spheres, we obtain the definition of charge—the unit charge being such that when at unit distance from an equal charge it is repelled with unit force. This formula is the foundation of all quantitative measurements in electrostatics. The completely general expression is ee'/kr^2 , where k is the dielectric constant or specific inductive capacity of the medium through which the force is being exerted.

Kelvin's quadrant electrometer consists of four hollow brass quadrants, which when fitted close together form a squat hollow cylinder bounded above and below by parallel plane faces. For electrical purposes they must, however, be drawn a little apart, so that when looked at from above or from below they have the appearance as shown in fig. 3—viz. that of a circular disc with two mutually perpendicular diametral clefts. Each quadrant is insulated on its own

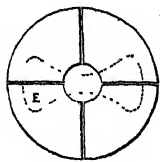

Fig. 3.

glass support; but each is joined to its opposite by a wire, A to A' and B to B' in fig. 4, so that

electrically they go in pairs. From one of each pair a vertical rod leads to the outside of the case in which the whole is enclosed. These rods are called the *electrodes*, and their function is to bring the pairs of quadrants into electrical connection with external bodies. The inside corner of the top and bottom of each quadrant is cut away, so that at the centre a small circular space is left concentric

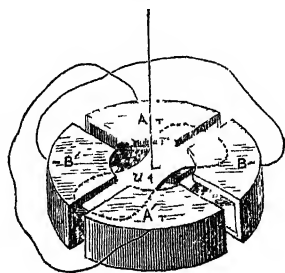

Fig. 4.

with the external cylindrical surface of the quadrants. In the hollow space enclosed by the quadrants a light charged body (E in fig. 3, u in fig. 4) of a convenient shape hangs, its axis of suspension passing up through the circular central space just mentioned. The light body can rotate about this vertical axis only, and its motion is controlled by the torsion of the suspension. If the four quadrants are all connected together, the suspension makes the light body hang so as to lie with its longer axis of symmetry parallel to one of the diametral clefts separating the quadrants. If, however, the pairs of quadrants are disconnected, and by connection with external bodies brought into different electric conditions, electrical forces will at once act upon the charged body and rotate it until they are balanced by the resisting torsion of the suspension. The motion is shown and measured by means of a beam of light reflected from a small mirror fixed to the vertical axis of suspension of the body and moving with it.

In the following experiments we shall suppose that all the conductors are of one metal, say brass; that they are at the beginning of every experiment insulated and unelectrified; that the electroscope or electrometer quadrants are likewise unelectrified at the beginning of each experiment; and that the dielectric is air.

Experiment I.—Set a cylindrical brass vessel on the electroscope; and let down into it, without coming into contact with it, a positively charged conductor A. It is convenient to hang this charged ball at the end of a short silk thread from the lid of the vessel, the lid itself being lowered or raised by means of a silk thread. As soon as the ball is brought inside the vessel the gold-leaves will diverge, as shown in fig. 5; and the vessel B, as regards outside objects, will behave as if positively electrified. Now touch B with the hand or with any non-insulating material connected to earth—in technical language, put the vessel to earth—and the gold-leaves will fall together, and all appearance of electrification will be destroyed. Remove the earth connection so as to insulate B once more, and lift away the lid and the attached ball, care being taken to prevent A coming in contact with B. The gold-leaves will again diverge, and the vessel B will be found to be negatively electrified.

The nature of the charge on the vessel and gold-leaves is indicated at once by the approach of an electrified body. If a piece of rubbed sealing-wax or any negatively charged body is brought near, the gold-leaves, if

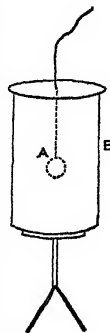

Fig. 5.

negatively electrified, will diverge still more; if positively electrified, will tend to fall together.

In thus charging the vessel B negatively by induction, we have in no way diminished the original positive charge on A; and we may use this same charge an indefinite number of times in charging negatively other bodies like B. In each body so charged by induction we have a new-formed source of energy, which has been derived from the energy spent in separating against their mutual attraction the positively charged ball and the negatively charged vessel.

Experiment II.—Begin again as in Experiment I., introducing the charged ball A into B, and putting B to earth, so that the gold-leaves fall together. Now connect A with B. No effect will be observed on the electroscope, even though, as in the former experiment, A should be removed. Thus the charge on A has been completely destroyed; hence there must have been on B, just before the contact was made, an equal but opposite charge. This is, in fact, the very charge which made its presence evident when, in Experiment I., the ball A was removed.

Thus, if a charged body A be completely surrounded by a closed vessel B, which is put to earth and then insulated, the charge induced on B is equal and opposite to the charge on A. To make this induced charge apparent we must remove A.

Experiment III.—Repeat Experiment I., and after having charged B negatively by induction, introduce A into another conductor C, initially without charge and insulated. If C also is resting on a gold-leaf electroscope, the gold-leaves will diverge with positive electrification as in the earlier stage of Experiment I. Bring A into metallic connection with C. If C completely surrounds A, no change will be observed on the electroscope, although a spark may be heard at the instant the contact is made. The ball A, if removed without again coming in contact with C, will be found to have lost all its charge; and if B and C are brought into metallic connection, all appearance of electrification on them also will be destroyed. In other words, the negative charge induced on B has been quite destroyed by union with the positive charge transferred to C. These charges, therefore, must be equal and opposite. Thus the charge originally on A has been wholly transferred to C.

We conclude, then, that when a conductor is electrified, its electrification resides wholly on the surface. Any portion of it removed from the inside will be found unelectrified if taken quite out of the influence of other electrified bodies.

This experiment, or one very similar to it, was performed in 1766 by Priestley, and in 1772 by Henry Cavendish, both of whom deduced from it that 'electric attraction and repulsion must be inversely as the square of the distance.'

Experiment IV.—To study in greater detail the properties of the electric field around a given charged conductor B, take two small insulated spheres and connect them by thin wires to the electrodes of the electrometer, each to one. Suppose these spheres to be at first in close contact at some part of the field; then, since the pairs of quadrants are in the same electrical condition, the electrometer will show zero deflection. Now gently separate the spheres, both insulated of course, and in general a deflection to the right or to the left will be obtained on the electrometer. By trial we may find the unique direction of separation which, for a given distance of separation, gives the maximum deflection. It will be found, however, that a separation of the spheres in directions at right angles to this unique direction does not cause any deflection on the electrometer. It is easier, indeed, to find the directions of separation for

which there is no deflection than to find the direction of maximum deflection for a given separation. Suppose in fact that the one small sphere is fixed in position, and that the other, which we may call the exploring sphere, is moved away from contact with it in such a manner that the electrometer always shows zero deflection. The centre of the exploring sphere will describe a curve, and can be made by successive trials to describe an infinity of curves, all lying on a certain surface which passes through the centre of the fixed sphere. We shall call this the surface S. Now, with the exploring sphere on this surface, let the fixed sphere be

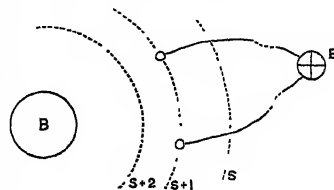

Fig. 6.

shifted in towards B till the electrometer deflection is unity. Then shift the exploring sphere correspondingly until the deflection is brought back to zero again, and proceed as in the first position to trace out a second surface, which we shall call $S + 1$, and which will pass through the centre of the fixed sphere in its second position. Shift the fixed sphere once more till unit deflection is obtained, follow up with the exploring sphere, and trace out the third surface $S + 2$. In this way, step by step, the electric field may be supposed to be mapped out by a series of surfaces, differing in value by unity as measured on the electrometer scale. We may pass out to the surfaces $S - 1$, $S - 2$, $S - 3$, &c., as well as in to the surfaces $S + 1$, $S + 2$, $S + 3$, &c. If the electrodes of the electrometer terminate on any one of these surfaces there is no deflection; if they terminate on different surfaces the deflection is the difference of the name-values of the surfaces. Evidently the conductor B is such a surface, for if the electrodes terminate on it, all the quadrants, being in metallic connection, will be in the same electrical condition, and the electrometer will show no deflection.

The surfaces we have just described are called *equipotential surfaces*, the term potential having in electricity much the same import as temperature has in heat or pressure in hydrodynamics. When a channel exists between two masses of fluid at different pressures, fluid will flow from where the pressure is higher to where it is lower. Similarly if we have two charged conductors whose electrical conditions as tested by electroscope or electrometer become changed after they have been connected by a wire and disconnected again, these two conductors are said to have been at first at different potentials. If they had been connected to the electrodes of the electrometer, each to one, the electrometer would have shown a deflection; and this deflection would have been a measure of the difference of potential. If the difference of potential is great, then the contact of the two conductors is evidenced by an obvious electrical discharge in the form of a visible audible spark.

Within an electric field we may suppose traced out, after the manner of the last experiment, a series of equipotential surfaces. To fix our ideas, let the one conductor be completely enclosed within the other—say a spherical globe within a concentric spherical shell—and let this outer shell be put to earth, and let us call its potential zero. The electric field exists only in the region between the shell and the globe, which we shall suppose to be at a high potential V . The symmetry of the system requires that the other equipotential surfaces will all be spheres concentric with the globe and shell. Now

we may compare this electrical system of globe, shell, and intermediate equipotential surfaces to a system of Contour (q.v.) lines representing a hill

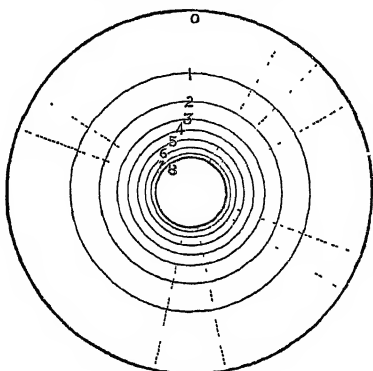

Fig. 7.

with a flat top rising up from the sea-level—the successive equipotential surfaces in the electrical system corresponding to successive equal-level lines in the geographical system. To carry one pound of matter from the sea-level up to the top of the hill requires so much work to be done against gravity (see ENERGY), and this amount of work is proportional to the height lifted through—i.e. to the number of contours crossed. So, in the electrical system, to carry a small positive charge from the shell to the globe will require so much work to be done against the electric forces, and this amount of work will be proportional to the number of equipotential surfaces crossed. Further, exactly as the pound of matter taken to the top of the hill will add to the height of the hill, so will the addition of this small extra charge to the globe increase its potential.

We have assumed in the above discussion that the successive equipotential surfaces, experimentally determined by means of the quadrant electrometer, are really such that the work done in carrying a given small charge over the interval separating any two contiguous surfaces is the same. It is usual in treatises on the subject to begin with the dynamical definition of the potential at a point as the work done in carrying a unit of positive electricity from infinity to that point. It is then shown that the quadrant electrometer is an instrument so constructed as to fit in to this definition.

Assuming, then, that our equipotential surfaces have the property just mentioned, we are in a position to study the energy relations of the electric field.

Coulomb established by experiment that the force of repulsion between two similarly charged bodies was directly as the product of the charges. Hence, as the charge of the globe enclosed in the shell is increased, the electric forces in the field increase in the same proportion. Hence the work done in carrying a given charge from the shell to the globe against the electric forces increases in the same ratio. In other words, the number of equipotential surfaces in the field grows uniformly with the charge. If the potential of the globe is V , we may write the charge CV , C being a constant so long as the geometrical dimensions of the system remain unchanged. Since the shell is always kept connected to earth—i.e. at zero potential—there is a charge $-CV$ distributed over the inside of the shell. To add a small extra charge to the globe may be regarded as equivalent to taking this small charge from the shell, carrying it across the dielectric, and

distributing it over the globe. The work done in effecting this is evidently proportional to the charge taken and to the number of equipotential surfaces crossed. But as the extra charge is added, let us suppose, at a steady rate, the potential of the globe is increased at a proportional steady rate. Hence the whole work done in adding a given charge is equal to the product of the charge and the mean potential of the globe during the operation. Thus, in charging the globe from zero potential to potential V , we do an amount of work equal to half the product of the final potential V into the final charge CV —in symbols $\frac{1}{2}CV^2$ or $\frac{1}{2}QV$ or $\frac{1}{2}Q^2/C$, where Q is the charge, and C the constant which depends on the geometrical dimensions of the system.

We have already seen that positive and negative electrifications always coexist—that it is impossible to generate a given positive charge without at the same time generating as much negative charge. Faraday took implicit account of this truth in his conception of lines of electric force traversing the dielectric. Since no work is done against the electric forces in passing along an equipotential surface, we readily see that the electric force at any point is perpendicular to the equipotential surface there. If, starting from any point, we move always perpendicular to the equipotential surface through which we are for the moment passing, we shall describe a curve which at every point of it is tangential to the direction of the electric force there. Such a curve is called a Line of Force. Take any small area on an equipotential surface, and draw lines of force through its perimeter. These lines of force will form a so-called Tube of Force, whose section in general will vary as we pass along it. Following this tube of force backwards to its source, we shall finally come to a positively charged conductor; and following it forwards, we shall ultimately come to a negatively charged conductor. Every such tube of force has, in short, two ends. It springs perpendicularly from a positively charged area, and terminates, also perpendicularly, on a negatively charged area. According to Faraday's view, and to the view now generally accepted, it is along these tubes of force that electric induction takes place; so that the negative charge on the terminal area is exactly equal to the positive charge on the area from which the tube springs.

Suppose, now, that in the region between the globe and shell of fig. 8 an insulated conductor originally unelectrified is introduced; or, what comes to the same thing, suppose a marked-off region in the electric field to become conducting, this region will at once be reduced throughout to the same potential, and its surface will form

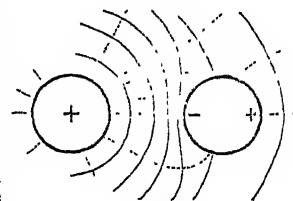

Fig. 8.

part of an equipotential surface. But, since originally the potential in this region fell steadily as we passed outwards from the globe, a transference of charge must have taken place also outwards in order that the potential should become equalised throughout. The introduced conductor, in fact, acts as a channel along which electrification is transferred; so that, if tested, the end facing the globe will be found negatively electrified, and the farther end positively electrified.

Now it is evident that the introduction of this conductor into the field has very much changed the configuration of the equipotential surfaces in its vicinity, the new configuration being something

like what is indicated in the diagram (fig. 8). As a consequence, the tubes of force, which are necessarily perpendicular to the equipotential surfaces, must also suffer a corresponding change of configuration. A certain number, springing from the globe, will fall perpendicularly on the nearer part of the introduced conductor; while from the farther part an equal number of tubes of force will spring and continue outwards to the shell. Where the tube ends on a conducting surface, there we find unit negative charge; and where it springs from a conducting surface, there we find unit positive charge.

Generally speaking, the effect of the presence of the introduced conductor is to crush the tubes of force in the neighbourhood closer together, and therefore (since this number remains constant) to compel an expansion of them elsewhere. The terminals of the tubes on the globe will obey the same tendency towards concentration and expansion. In other words, the charge Q , at first distributed uniformly over the globe, becomes redistributed and tends to accumulate on the side facing the conductor. The nearer the conductor and globe are brought, the greater will this tendency be; and at last, when they are near enough, the dielectric is unable to sustain the high electric tension along the ever-shrinking tube of force. It yields, a more or less sudden transference of charge takes place in the form usually of a spark, the potentials of the globe and conductor are practically equalised, and the tubes of force between them are annihilated. This is the phenomenon which is exhibited on a large scale in every lightning-flash, and on a small scale in every spark between electrified bodies.

Suppose, however, that before this catastrophe has taken place the conductor is joined by a wire to the surrounding shell, and consequently brought to zero potential. All those equipotential surfaces which at first enclosed the conductor—i.e. lay between it and the enclosing shell—will be shifted so as to lie between it and the globe. The tubes of force will shift correspondingly; and as no tube can now pass from the conductor to the shell, none will spring from it. Hence the charge on the conductor will be wholly negative. Now experiment shows that when the conductor is brought to zero potential in the way just described, a spark always passes at the instant the connection is made. This spark means so much energy in the form of light, sound, and heat, and must therefore mean a disappearance of energy in some other form. This cannot be other than electrical energy. But the charge on A has not changed, so that the number of tubes of force is exactly as before. The change must therefore be in the potential difference along the tubes of force; and since the shell and the conductor are at zero potential, the diminution must take place in the potential of A . Thus we see that the potential of a positively charged body is diminished if a conductor at zero potential is brought near it.

This result leads naturally to the discussion of capacity. The capacity of a conductor is measured by the ratio of its charge to its potential. Hence if, as in the experiment just described, we have a diminution of potential with constant charge, this is equivalent to an increase of capacity. The greater the capacity of a conductor, the greater the charge it can hold at a given potential. Hence if a number of conductors are at the same potential, the charges must be distributed amongst them directly as the capacities. The experiment just described shows how we may arrange matters so as greatly to increase the capacity of a given conductor. It is sufficient to have close to it another conductor at zero potential. Such an arrangement of conductors is called an *accumulator* or *condenser*; and the most familiar form of accumulator used in

electrostatic experiments is the Leyden jar, so called from the city where, in 1745, its properties were accidentally discovered by Cuneus. About the same time, possibly a month or two earlier, almost exactly the same discovery was made by Kleist at Kammin in Pomerania. In its modern form, a Leyden jar is a cylindrical glass bottle, lined inside and outside with metal foil up to within a short distance from the top. A brass rod connected below with the inside coating passes upward through the cork or stopper, and terminates generally in a ball or knob. A Leyden jar, then, consists essentially of two conductors, the one almost completely enclosed in the other, and separated from it only by the thickness of the dielectric. If either conductor is put to earth, and the other insulated and charged, an opposite and nearly equal charge is induced on the former. If we could completely surround the one conductor by the other, the induced charge would, as we have seen, be exactly equal but opposite to the inducing charge. Leyden jars are indispensable for carrying out illustrative experiments in electricity.

Fig. 9.

The essential nature of the mode of action of an accumulator or condenser may be illustrated as follows: Take any charged conductor with its associated electric field. Let Q be its charge, V_0 its potential, so that $\frac{1}{2}QV_0$ is the measure of the electric energy stored up in the field. Having fixed our attention upon any equipotential surface V_1 enclosing the conductor, let us suppose this surface to become conducting. There will be no transference of charge over this surface, because it is from the very beginning an equipotential surface. There will be no change of the electric field either inside or outside the surface V_1 ; but these two regions will now be separated by a conducting surface. So far as the outside region is concerned, we may regard the charge Q as distributed over a conductor coextensive with the conducting surface V_1 , and may quite disregard the existence of the original conductor at potential V_0 . The electrical energy stored up in this outside region is therefore a $\frac{1}{2}QV_1$. Let us now connect this new-formed conductor to earth so as to reduce it to zero potential. By so doing we discharge the conductor, completely destroying the electric field outside

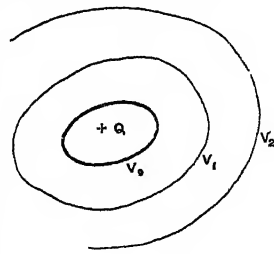

Fig. 10.

of it and the $\frac{1}{2}QV_1$ units of electric energy stored up in it. This therefore is energy lost to the original system; and the energy stored up in the dielectric separating the two conductors becomes a $\frac{1}{2}Q(V_0 - V_1)$. Now, since the enclosing conductor has been reduced to zero potential, the quantity $(V_0 - V_1)$ must represent the new potential of the enclosed conductor.

In short, the bringing of the enclosing conductor to zero potential, being a purely external electrical change, has in no way altered the configuration of the equipotential surfaces and tubes of force inside; it has simply reduced the potential values throughout by the same amount—viz. the potential of the enclosing conductor before it was put to earth. The potential of the enclosed conductor has fallen from V_0 to $V_0 - V_1$; and hence, as the charge Q has

remained unchanged, the capacity has increased in the ratio $V_0 - V_1 : V_0$. Thus, with either conductor fixed in size, the capacity of the system grows greater and greater as the thickness of the separating dielectric is diminished. It is easily shown that for a condenser built up of closely opposed surfaces, whether plates or cylinders, separated by a given dielectric, the capacity varies inversely as the thickness of the dielectric.

Let a sphere of radius a be charged with Q units of electricity; then, according to Newton's well-known theorem, the electric force at distance r due to this distribution is Q/r^2 . Hence at a point close to the surface of the sphere the force is Q/a^2 . The surface density on the conductor, or charge per unit area, is $Q/4\pi a^2$, and this may be written $F/4\pi$, where F is the electric force. Thus the electric force at a point close to the sphere is equal to 4π times the surface density.

This important relation has been established for the sphere, but it may be easily generalised for any form of conductor. Whatever form the conductor may have, the electric force in the interior is zero, the charge distributing itself in such a way as to effect a balance at all interior points. When the conductor is elongated in form this consideration requires that the surface density is greater at the ends than anywhere else; and, generally, the charge tends to accumulate towards pointed parts of a conductor. It is in the neighbourhood of such regions that we find the strongest electric forces.

This accumulation of electric charge towards the ends of a pointed conductor is well exemplified in the lightning-conductor, which is simply a very elongated piece of metal in contact with the earth. A charged body of air, such as we have accompanying a thunder-cloud, passes near it. The tubes of inductive force are at once concentrated on the elongated conductor; the electric force at the point becomes so intense that the air can no longer act as a perfect insulator; electrical discharge takes place along these very tense tubes of force; and in a more or less gradual manner the cloud is robbed of its charge, and the evil effects of a sudden lightning-flash minimised. On the same principle, electric discharge through air is facilitated by the use of pointed conductors, such as the combs which are so important a detail in machines for generating electricity by means of friction.

We have seen that the capacity of a condenser depends upon the distance between the surfaces or plates which compose it; it also, however, depends very materially on the nature of the dielectric. Suppose, for example, that we have a series of condensers, made of the same conducting material, and all exactly equal as regards their geometrical and space relations, but all differing as regards the dielectric which separates their plates. Thus let one have air as its dielectric, another plate-glass, another paraffin, another mica, and so on. Let them now all be brought to the same potential, then disconnected and tested as to charge. The charges will be found to be all different—being in the four cases we have mentioned approximately proportional to the numbers 1, 6, 2, 6.6. These four numbers are the values of what is termed the *specific inductive capacity*, or dielectric constant, of air, glass, paraffin, and mica. Thus by merely inserting a plate of mica between two plates of an air condenser, we increase the capacity by as much as if we had approached the plates in air through a distance equal to .85 ($=5/6 \cdot 6$) of the thickness of the mica.

We may now fitly consider the principles of action of the various machines that are used for generating electricity. The rubbed pieces of resin, sulphur, glass, &c. were gradually succeeded by spheres, cylinders, and circular plates of these

materials, which, as they revolved against prepared rubbers, were kept in a constant state of electrification. Any insulated conductor brought near enough to a portion of such a cylinder or plate at a distance from the rubber will become charged, the dielectric strength of the air breaking down exactly as in the case of the lightning-conductor and the thunder-cloud. Such is the action of the ordinary frictional machine; obviously the conductor acquires a charge similar to that on the revolving cylinder or plate. The opposite charge on the rubber may be transferred to another conductor, which is usually put to earth. Le Roy's or Winter's plate machine is shown in the diagram (fig. 11).

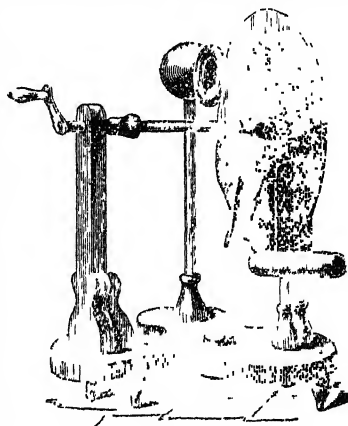

Fig. 11.

Essentially different in its action is the electrophorus, invented by Volta in 1771. In its most improved modern form it consists of two plates, one of metal, and the other of resin, vulcanite, or ebonite backed with metal. Insulating handles can be screwed on to the backs of the plates; and one plate at least must be so insulated. The surface of the ebonite is first electrified by friction, and the metal plate is brought into close contact with it. The metal plate, from its greater proximity to the negatively charged surface of the ebonite, will be at a lower potential than the metal back to the ebonite. If these are then brought into contact—conveniently effected by means of a metal pin passing through the ebonite—a transference of charge will take place, so that the metal plate when lifted away will be found positively charged.

In Nicholson's 'revolving doubler' we have the parent form of a number of rotatory machines which, like the electrophorus, depend for their action upon induction and convection. They make direct use of the principle of 'doubling' discovered by Bennet, by which the difference of potential between two conductors is indefinitely increased. Kelvin's replenisher, which is an important part of the quadrant electrometer in its perfected form, is perhaps the simplest and most compact of these machines. In it a turning vertical shaft of ebonite bears, at the ends of a horizontal cross-piece of ebonite, two metal pieces called carriers (cc in the diagram, which represents a horizontal section). These carriers rotate in the region between two insulated metal inductors (a, b) in the form of cylindrical segments. When the carriers are in position AB , they come into momentary contact with delicate springs attached to the neighbouring inductors; and when they are in position CD , they come into momentary contact with delicate springs connected by a metallic arc which is quite insulated from the inductors. Suppose a to be at a higher potential than b , and consider what takes place as cc rotates counter-clockwise, as shown by the arrows in the figure. In the position AB the carriers are well surrounded by the metal shields, and will part with nearly all the charge that may chance to be upon them. Just before they come

into contact with the springs in position CD, the two carriers are at different potentials. Hence at the moment of contact with the connecting

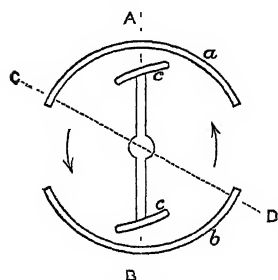

Fig. 12.

every complete revolution each carrier becomes once negatively charged and once positively charged, giving up its negative charge to the one inductor, and its positive charge to the other.

The same principles of induction and convection are made use of in the so-called influence machines, which in recent years have quite eclipsed the older frictional machine. These are generally known by the name of their inventors, such as Topley, Holtz, Bertsch, Voss, and Wimshurst. Of these, the Wimshurst is one of the best known. It consists of two circular glass plates, mounted on a common spindle, and capable of rotation in opposite directions with equal speeds. Each plate carries twelve or sixteen strips of thin sheet-metal, fixed radially at regular intervals apart. These strips lie on the outside of the closely opposed glass plates. At the extremities of the horizontal diameter of the plates the main conductors are placed, insulated on glass or vulcanite pillars. Horizontal arms with the usual combs project inwards, embracing both plates as far as the inner ends of the metal strips. In front is fixed a diagonal conductor, called a 'neutralising rod'; and a similar rod is fixed behind at right angles to the one in front. These neutralising rods terminate at both ends in a small metal brush, which touches the metal strips or carriers as they pass. By this contact of brushes and strips, every strip on either plate is, very soon after it has

plenisht—the carriers as they leave the bushes of the neutralising rod will acquire a charge, negative or positive, according as they are nearer the positively or negatively charged main conductor. But, evidently, each carrier on the one plate will act as inductor to the carriers on the other plate; and a moment's consideration will show that this inductive action will everywhere accentuate the inductive action of the main conductors. Thus the positive conductor is being fed by the positive charges brought by the strips on the upper half of the one plate and on the lower half of the other; while the negative conductor is being fed by the negative charges brought by the strips on the lower half of the one plate and the upper half of the other. The main conductors are provided with arms, which reach out towards each other, and between whose terminal knobs discharge takes place.

So far we have confined our attention almost entirely to electrostatic phenomena—i.e. to phenomena connected with the existence of a steady electric strain in dielectrics. When compelled to deal with the transference of so-called charge from conductor to conductor, we had regard rather to the initial and final equilibrium conditions than to the intermediate condition of change. This condition of change, however, has clearly very important energy relations. In all cases of electrical discharge there is, in the language of Faraday, a concentration of the lines of force in a certain region of the dielectric, until that becomes, as it were, overstrained, and yields with a more or less evident appearance of part of the energy of strain in the form of light, sound, and heat. It can be shown that when a charge is allowed to pass from one conductor to another at a lower potential, there is always loss of energy, which is proportional to the square of the charge which passed.

Thus, let there be two insulated conductors of capacities C and C' , originally at different potentials. If they are brought to the same potential V by being connected by a thin wire of comparatively insignificant capacity, the original charges on the conductors will become redistributed, and the final charges will be CV and $C'V$. Whatever charge the one conductor has lost, the other has gained. Hence we may write the original charges as $CV + q$, $C'V - q$, where q is the charge which has been transferred from C to C' . Now the energy of any charged conductor is measured by half the charge into the potential or half the square of the charge divided by the capacity. Thus the final energy, after equalisation of potentials, is

$$\frac{1}{2}CV^2 + \frac{1}{2}C'V^2,$$

while the initial energy was

$$\frac{1}{2} \frac{(CV + q)^2}{C} + \frac{1}{2} \frac{(C'V - q)^2}{C'} = \frac{1}{2}CV^2 + \frac{1}{2}C'V^2 + \frac{1}{2}q^2 \left(\frac{1}{C} + \frac{1}{C'} \right).$$

Hence, since $\frac{1}{2}q^2 \left(\frac{1}{C} + \frac{1}{C'} \right)$ is always positive, we

see that the initial energy is necessarily greater than the final energy. The loss of energy is represented by a quantity which is proportional to the square of the charge that has been transferred. If we look more closely into the significance of this quantity, we see that it represents the electrical energy of the system of two conductors of capacities C and C' when they are charged each with q units of either positive or negative electricity; or, more particularly, it represents the work which must be done in carrying q units from the one to the other. This is an example of the general principle that the work done by the electric field

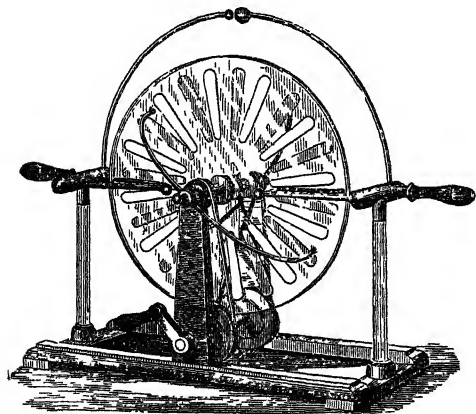

Fig. 13.

passed under the collecting combs, brought into metallic connection for a moment with the strip diametrically opposite it on the same plate. Suppose the principal conductors to be at different potentials; then—exactly as in Thomson's re-

in compelling a transference or flow of electricity from one region to another is exactly equal to the work which must be done against the electrical forces in carrying an equal quantity of electricity back again.

It is convenient, especially when the flow of electricity is the subject of consideration, to use the term *Electromotive Force* instead of *Difference of Potential*. We may suppose it measured by means of the quadrant electrometer. Thus if the regions A and B are connected severally to the electrodes of the electrometer, the deflection will measure the electromotive force acting along any conducting channel which may be supposed to bring A and B into communication. The flow of electricity which this electromotive force compels will tend to bring A and B to the same potential; and in the ultimate vanishing of the deflection on the electrometer we have the evidence of such a flow having taken place. But we may suppose that, by some means, notwithstanding the conducting channel between A and B, their difference of potential is sustained, so that the electromotive force acting along the channel is kept constant. Then the electrometer will show a steady deflection, while at the same time a steady flow of electricity will take place along the channel. This flow, whose existence is indicated only indirectly by the electrometer, must be measured by some one of its direct effects.

These effects are conveniently grouped into physiological, thermal, chemical, and magnetic.

The electric 'shock,' experienced when the experimenter uses himself as a discharging conductor, is a familiar example of the physiological effect of an electric current. The electric discharge causes a muscular contraction. In 1786 Galvani observed that the limb of a frog, when touched simultaneously by two different metals in contact, was convulsed exactly as if subjected to an electric shock; and Volta, following up this observation, discovered in 1800 a new source of electromotive force which could sustain an electric current through a conductor for a lengthened period of time. From this dates the development of Galvanic or Voltaic or current electricity. The electric shock, however, depends upon *variations* in the amount of flow; a steady current produces no shock, except when it is beginning or ending.

In the electric spark there are thermal effects; and generally, since a transference of charge or flow of electricity means a loss of electric energy, an evolution of heat is a necessary consequence.

Towards the close of the 18th century the decomposition of water by an electric discharge was observed by Van Troostwijk and Deiman; while with Volta's electrical discoveries a new era in chemistry as well as in electricity was inaugurated.

None of these effects, however, give a ready method for measuring a steady electric current—i.e. the amount of electricity which is transferred across any section of the conductor in a second. For this we must go to the fourth group—viz. the magnetic effects of currents. This branch of the subject, which includes electro-magnetism, and as a consequence much of electro-dynamics, dates from 1820, when Oersted of Copenhagen discovered that every electric current tends to make a magnet set itself perpendicular to the direction of the current. To make the effect specially apparent, the wire conveying the current should be coiled again and again round the region in which the magnet is placed. The same current is thus brought again and again into the vicinity of the magnet, and has a proportionately greater effect. An instrument consisting of a coil of wire surrounding a magnet which is free to rotate in some plane passing through the axis of the coil is called a

galvanometer. The coiled wire must be covered with gutta-percha, silk, or cotton thread, so that the contiguous coils may be insulated from each other; and, for ordinary purposes, the plane of the coil should contain the magnet when no current is flowing. We may suppose the magnet to be suspended horizontally under the influence of the earth's magnetic field; then the plane of the coil should contain the magnetic meridian (see *MAGNETISM*). The ends of the coiled wire are called the terminals of the galvanometer. When they are connected to conductors at different potentials, a current will flow round the coil of wire, and will indicate its presence by compelling the magnet to move out of its normal position of equilibrium. The tendency of the current in the coil is to make the magnet turn itself at right angles to the plane of the coil—i.e. to set itself along the axis of the coil, magnetic east and west. But this is resisted by the steady action of the earth's magnetic field. The result is a compromise, and the magnet is deflected from its normal position in the magnetic meridian through an angle which depends on the relative values of the current and the earth's magnetic force. Since the latter is practically constant, the angle of deflection will depend on the value of the current, being greater for the greater current.

In discussing the equalisation of potential in electrostatics, we purposely confined our attention to one metal only. The reason was simply because, in general, two different metals, or in fact any two different conductors, can never when in direct contact be at the same potential. The discovery of this fact we owe to Volta. Take, for instance, any four conductors B A X B, put them in series as in the figure, and connect the terminal members, which are of the same material, to the electrometer. According to the character of the conductors AXB, there may be, or there may not be, a deflection on the electrometer.

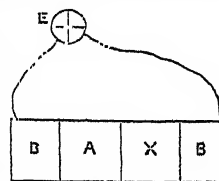

Fig. 14.

(1) If there is no deflection, the two B's are at the same potential; and yet, according to Volta's discovery, the three different substances are at different potentials. This may be shown at once by breaking the chain at any of the separating surfaces, when a deflection on the electrometer will be observed. During this act of separation the separating surfaces, one of which must of course be kept insulated, act like a condenser with a constant charge, the difference of potential changing because the capacity is changing. The reason why the B's are at the same potential is that, whatever be the differences of potential between B and A and between A and X, the difference of potential between X and B is always such as to restore B to its original value.

(2) If, however, there is a deflection produced on the electrometer, then we know that the two B's must be at different potentials, so that, if we connect them by wires to the terminals of the galvanometer, a current will be observed to flow. Such a combination of materials, in which two conductors of the same material are kept at different potentials by being linked together by at least two other and different materials, is called a voltaic or galvanic cell. If we join the two terminals either directly or by means of any other simple conductor, a current will necessarily flow round the circuit. But this current means a transference of charge from one conductor to another at a lower potential—i.e. a loss of electrical energy which is proportional to the square of the quantity transferred.

Hence, if, as is practically the case, the electromotive force or difference of potential remains fairly steady, it must be because electrical energy is supplied as fast as it is being lost. Consequently there must be in the circuit somewhere an original source of energy. In fact, it is found that a permanent electromotive force of the kind just described is always associated with a tendency to chemical action between two at least of the members of the chain; and that, when the circuit is complete and the current is flowing, chemical changes are going on within the cell.

There are innumerable forms of voltaic cells, built up in different ways of different materials. Copper and zinc dipping into dilute sulphuric acid is one of the simplest forms. When the cell is closed—i.e. when the copper and zinc are joined externally by a wire—a current will be obtained flowing in the wire from the copper to the zinc. At the same time the zinc will be dissolved in the acid; and it is from the energy set free by this chemical action that the electrical energy is derived. Such a single fluid cell is not, however, very steady in its action. We shall therefore take as a type of a good cell one of the class known as two-fluid cells; and of these we shall choose the Daniell cell. In its best form, the Daniell cell consists of copper and zinc plates dipping into saturated solution of sulphate of copper and semi-saturated solution of sulphate of zinc respectively—the liquids being also in contact but prevented from mixing by a porous septum. Connect the copper and zinc plates, or *poles*, as they are technically called, to the electrometer. A deflection will be produced which will measure the electromotive force of a Daniell cell when it is not being used for the production of currents—i.e. when it is *open*. We shall take this, provisionally, as our unit electromotive force, and we may suppose the electrometer scale graduated so as to show unit deflection when the poles of a Daniell cell are connected to the electrodes of the electrometer. The deflection is such as to indicate that the electrode connected to the copper is at the higher potential. Hence the copper is called the positive pole, and the zinc the negative pole.

Take now a second Daniell cell, connect its zinc to the copper of the first one, and connect the free poles to the electrometer. The electromotive force of the two cells so joined will be double that of one—i.e. equal to 2. And generally, when a number of cells are arranged in series (i.e. with the zinc of the first joined to the copper of the second, the zinc of the second to the copper of the third, and so on), the electromotive force of this battery, in terms of the electromotive force of one cell, is just the number of cells composing it. Theoretically there is no limit to the electromotive force obtainable by means of cells; practically the difficulty consists in keeping a large number of cells in good condition. With a large enough battery we can obtain effects in every way analogous to the effects produced with frictional electricity.

If, at the same time that the poles of a cell are connected to the electrometer, they are connected by stout short wires to the terminals of the galvanometer, the galvanometer needle will be deflected, while the electrometer deflection will be unchanged, or at the most diminished slightly. If thin long wires are substituted for the thick short connections, a very great diminution will be observed in the galvanometer reading, and perhaps a very slight increase in the electrometer reading, the apparent electromotive force of the closed cell approximating more closely to the electromotive force of the open cell. Thus we may alter the current at will by employing different lengths and different thicknesses of wires for transmitting the current; and yet the electromotive force between

the poles of the cell is but slightly, if at all, affected. In other words, the current, as measured on a galvanometer, depends not only on the electromotive force acting along the channel, but upon some property of the channel itself—some property independent altogether of electromotive force.

This property we may indicate by either of two words—viz. Conductance or Resistance. These words denote contraries. Thus a body of small conductance has a great resistance, and a body of low resistance has a high conductance. Quantitatively, the one is the reciprocal of the other; and they are measured in terms of current and electromotive force by what is known as Ohm's Law, enunciated by Ohm in 1827. We now know (see *The Electrical Researches of the Hon. Henry Cavendish*, edited by Maxwell, 1879) that Cavendish had in 1781 established this law, and compared the resistances of iron wire and various saline solutions to electric discharge through them. He acted as his own galvanometer, and compared discharges by their 'shocks.' As regards the historical development of the science, however, it is to Ohm that we owe the full statement of the Law (1827). Since Ohm's day the law has been subjected to the severest experimental tests that the scientific mind could imagine, and has stood them all. It is really the basis of our whole system of electrical measurements. Ohm's Law in its modern form asserts that the resistance of a conductor is measured by the ratio of the electromotive force between its two ends to the current flowing through it. Thus, if E is the electromotive force as measured on the electrometer, and C the current as measured on the galvanometer, and if K , R measure the conductance and resistance respectively, Ohm's Law gives us these relations:

$$EK = C, E = CR.$$

The peculiar value of Ohm's Law lies in the fact that the measure of the resistance, though defined in terms of electromotive force and current, is always the same, so long as the physical condition of each conductor remains unaltered. The proportionality of current and electromotive force in a given circuit implies this.

If a steady current is flowing along a conductor of one kind of material, say a copper wire, the potential will fall off continuously as we pass along in the direction of the current.

Let AB be the wire, and suppose the current to be flowing from A to B . Join B to one electrode of the electrometer; and let a wire from the other electrode be led to any point P on the wire. Then as the point of contact P is moved up towards A , the electrometer deflection will increase continuously.

The measurement or, more strictly, comparison of resistances is one of the most important operations in the modern science of electricity. For this purpose we first choose a certain standard, say a particular length of a particular piece of wire at a certain temperature. It is obviously convenient to have a standard which can be exactly reproduced should the first standard be lost or in any way damaged. Hence scientific men of all nations have agreed to use as the unit of resistance or Legal Ohm the resistance of a column of pure mercury 106.3 millimetres long, of uniform cross-section, and of mass 14.4521 grammes, the temperature

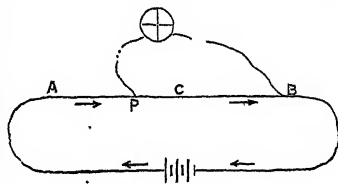

Fig. 15.

being that of melting ice. This is the more practical way of expressing that the section should be a square millimetre.

Such a mercury standard, though fulfilling the very necessary condition of accurate reproduction, is not convenient for practical use. For this purpose copies of the ohm must be made in solid wires of some metal or alloy.

If we put any number of single ohms end to end in series, we shall get a whole resistance equal to as many ohms as there are conductors. This is easily shown to be an immediate consequence of Ohm's Law. For, since it is the same current that is flowing through all the single ohms, the fall of potential as we pass from beginning to end of any one is the same for all; hence the fall of potential as we pass along, say, three is three times the fall as we pass along one; hence, the current being the same for the three as for the one, the resistance of the three must be 3 ohms. A special case of this is that the resistance of a wire, otherwise constant in its physical relations, is directly as the length. The completely general statement is that the resistance of any single continuous channel is the sum of the resistances of its parts.

Suppose, however, that the single ohms are so arranged that they all begin at one point, A, in the

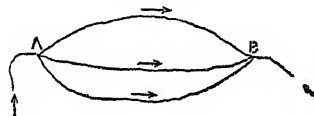

Fig. 16.

the circuit, and end at another point, B. Then it is clear that they must all be traversed not by the same current, but by equal currents. Hence there will flow into A and out of B a current equal to the sum of all these equal currents. Thus, if there are, say, three single ohms connecting A and B, the total current flowing into A and out of B must be three times the current flowing in any one of the branches. But for constant electromotive force the current is directly as the conductance, or inversely as the resistance. Hence the conductance of the threefold conductor between A and B is three times the conductance of any one of its components; or, otherwise, the resistance between A and B is one-third of an ohm. In like manner, the resistance of a wire, otherwise constant in its physical relations, is inversely as the area of its cross-section. The completely general statement is that the conductance of a multiple channel whose branches all begin at one point and end at another is the sum of the conductances of the branches. Conductors arranged in multiple arc in the way just described are generally said to be arranged *in parallel*.

The most obvious way of comparing the resistances of two conductors is to compare the deflections produced on a galvanometer when the conductors are inserted successively as part of a given circuit containing a constant cell and the galvanometer. But this method cannot attain a greater accuracy than is possible in reading the deflections; and the method is open to the further practical objection that the electromotive force of a cell varies slightly when the resistances of the circuit are changed. The comparison of resistances may, however, be effected by the method known as the Wheatstone bridge, without so much as a single measurement of either electromotive force or current.

Consider the case represented in fig. 17, in which the current from a battery is made to flow along two distinct channels from A to B. Along each the potential falls from its value α at A to its value β at B. Hence for any point P in the one branch

there must be a corresponding point Q in the other which has the same potential, β , say. Let the points P and Q be joined to the terminals of the galvanometer, G. Because of the equality of the potentials at P and Q, no current will flow through the galvanometer, however strong the currents may be in APB and AQB. Thus, as no current flows between P and Q, the current in AP must be the same as the current in PB, and the current in AQ must be the same as the current in QB. Hence, by Ohm's Law, the resistances of AP and PB must be proportional to the electromotive forces acting along them—i.e. in the ratio $(\alpha - \beta)/(r - b)$. Similarly the same ratio expresses the ratio of the resistances of AQ and QB. Thus the existence of no current in the galvanometer circuit—a condition which admits of the most delicate of tests—implies that the resistances of the four branches AP, AQ, PB, QB form a simple proportion, any one forming the fourth proportional to the other three properly taken. Two equal lengths cut off from a uniform wire have equal resistances. Let them be the branches AP, AQ. Let PB be the standard ohm. Then, by adjusting the length QB of a given wire till no current flows through the galvanometer, we obtain a copy of the ohm, accurate if the resistances AP and AQ are really equal to each other.

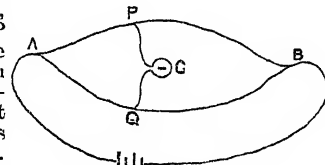

Fig. 17.

The resistance of metals increases with temperature; and this has led to the construction of what is known as the platinum thermometer, in which the resistance of a platinum wire, as indicated on a specially designed Wheatstone bridge and galvanometer, gives at once the temperature of the wire, and therefore of the region where the wire is. Recently Kamerlingh Onnes has found that at the temperature of liquid helium the conducting power of mercury, lead, and tin becomes suddenly so great as to render the resistance practically zero. When the metal is in this condition of superconductance, its conductance becomes markedly diminished when it is placed in a strong magnetic field greater than a certain critical value. In other words, when the resistance has become zero at a temperature of 2° or 3° Absolute, it recovers its finite value when the metal is placed in a strong enough magnetic field. That is to say, the influence of the magnetic field on the metal at very low temperatures is the same as a rise of temperature; both influences increase the resistance.

In non-magnetic metals at ordinary temperatures the effect of the application of a magnetic field is to increase the resistance or diminish the conductance. This is particularly in evidence when the magnetic lines of force are transverse—that is, at right angles to the direction in which the resistance is being measured. In the case of nearly all substances the change of resistance is very small, and is appreciable only in fairly strong magnetic fields. In the case of bismuth, however, the change of resistance in a transverse magnetic field is comparatively large; and the phenomenon has been utilised in the construction of a convenient apparatus for measuring strong magnetic fields. It consists of a flat spiral of bismuth, which when inserted into a strong magnetic field like the air-gap of an electro-magnet measures by its change of resistance the intensity of the transverse magnetic force.

The effect of magnetism in changing resistance is much more strongly marked in the magnetic

metals, iron, nickel, and cobalt; and there is the further peculiarity that in a transverse field the resistance of these metals is, in general, diminished, and not increased. When the magnetic force is applied along the direction in which the resistance is being measured, the resistance is, however, increased, as in the case of the non-magnetic metals. These phenomena have not as yet been wholly explained in terms of the electron theory of conduction.

The electrical resistance of substances is also affected by mechanical strain; but the effects are very small, and although of great interest in connection with electrical theory, they have no practical applications.

We have already seen that the passage of an electric current means a loss of electric energy. What becomes of this energy—i.e. into what other form is it transformed?—is a question which requires to be answered. It was early recognised that the electric current and electric discharge had a heating effect on the conductor along which the current flowed or the discharge took place; and in 1840 Joule published the important result that 'when a current of voltaic electricity is propagated along a metallic conductor, the heat evolved in a given time is proportional to the resistance of the conductor multiplied by the square of the electric intensity.' The heat so evolved fully accounts for the electric energy lost. Suppose we have an electromotive force E driving a current C through a resistance R . E is the measure of the work done in transferring unit of electricity along the channel. Now C is the amount of electricity transferred in a second of time. Hence the product EC measures the work done per second by the electromotive force in driving the current C . But by Ohm's Law

$$EC = RC^2;$$

and this is the very quantity which Joule showed appeared as heat in the wire.

If a very thin wire forms a part of a circuit, it is there that we shall best observe the effect of the heating. For the heat evolved per unit length of any conductor is directly as the resistance—i.e. inversely as the cross-section. But with the circuit all of one material, the rise of temperature is directly as the heat evolved and inversely as the mass heated; and the mass per unit length is directly as the cross-section. Thus the rise of temperature is inversely as the square of the cross-section—i.e. inversely as the fourth power of the diameter.

This is the principle of construction of the incandescent electric lamp, now so common a source of illumination (see ELECTRIC LIGHT). A thin filament of carbon is made to glow by the passage of a powerful current along it. To prevent the 'burning' away of the carbon in air, it is enclosed in a hermetically sealed glass vessel quite empty of oxygen.

So long as we are dealing with metals or simple conductors like carbon, the currents derived from the Daniell cells in the circuit do not appreciably change in value from the first instant onwards for several hours. If the currents are powerful enough, there will be slight diminution during the first few minutes, due to the heating of the conductors; for the resistance of nearly all metals increases with rise of temperature. But this effect will not in general be appreciable.

A very different set of phenomena confronts us when we introduce into the circuit a conductor like a solution of sulphuric acid, or of any sulphate, or indeed any ordinary chemical compound, either in solution or in a state of fusion. Such conductors can transmit currents only at the expense of their constitution; or, in the words of Faraday, in them 'the power of transmitting the electricity across the substance is dependent upon their capability

of suffering decomposition.' Such substances—the whole terminology of the subject was introduced in 1834 by Faraday—are called *electrolytes*; the conductors by which the current enters and leaves the electrolyte, the *electrodes*; and the whole process by which chemical compounds are decomposed by means of electric currents is named *electrolysis*.

Take, for example, a dilute solution of sulphuric acid nearly filling a glass vessel. Dip into this electrolyte two platinum strips, some little distance apart and not touching. These are the electrodes; and it is important in such an experiment to choose as electrodes materials for which the electrolyte has no chemical affinity. In this respect platinum is, over all, by far the most satisfactory. Now connect the one platinum strip to one pole of a Daniell cell, and the other to one of the terminals of the galvanometer. The other terminal of the galvanometer and the other pole of the cell may be connected at will, so as to complete the circuit. When in this way the circuit is completed, a current will be observed flowing through the galvanometer; but this current will very soon become extremely feeble, and, even though it may not altogether vanish, will produce no continuous decomposition of the fluid. Let now a second Daniell cell be added as shown in fig. 18, where B is the battery of two Daniell cells, G is the galvanometer, and C is the electrolyte. Then the galvanometer will indicate the existence of a pronounced current, which during the first few moments will fall considerably below its original intensity, but will ultimately reach a steady value. At the same time small bubbles of gas will appear at the surfaces of both electrodes, and will form steady ascending streams in the electrolyte. These products, or *ions*, as Faraday called them, may be collected in separate vessels, as shown in fig. 20, where the gases accumulate at the top of test-tubes inverted over the electrodes, gradually pushing out the liquid which at first filled these tubes. It will be noticed that the volume of gas given off from the one electrode is twice that given off from the other; so that if the test-tubes are exactly the same size, the one will become quite emptied of liquid when the other is only half-emptied. The greater volume of gas accumulates over the electrode by which the current leaves the electrolyte. When tested, the gas which comes off in greater quantity will be found to be hydrogen, and the other oxygen. In fact, we have here separated from one another the constituents of water— H_2O . Thus, whatever the intermediate stages of the process may be, the final result of passing a current through dilute sulphuric acid is to obtain the chemical constituents of water.

The characteristic points to be noticed here are that one Daniell cell cannot decompose water; that when two or more are used, the current markedly falls off in intensity during the first few moments; and that, when the current has become constant, steady streams of bubbles of gas ascend through the liquid from the surfaces of the electrodes, and from them only. These are some of the characteristics peculiar to electrolytic conduction; and, when present, any one of them is sufficient to distinguish an electrolyte from a simple conductor.

To study more closely the second point indicated, take two platinum strips p , q , thoroughly cleaned by heating in a flame to bright redness, dip them into the electrolyte, and connect them to the electrometer. The electrodes being both clean, platinum will have the same contact electromotive force with the electrolyte, so that they will be at

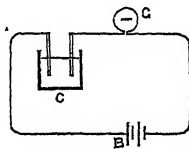

Fig. 18.

the same potential. Hence the electrometer will show zero deflection. Now put the electrolytic cell in circuit with the galvanometer and a battery of two or more Daniell cells; and suppose the current to flow from p to q through the electrolyte.

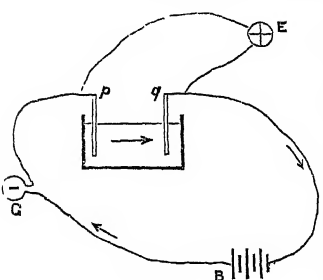

Fig. 19.

Then it may be observed that, as the current through the galvanometer falls off during the first stages, the difference of potential between p and q as measured on the electrometer increases. If we apply Ohm's Law to the portion between p and q , we see at once that the ratio E/C has considerably increased. This ratio, which for simple conductors measures the resistance, we shall speak of as measuring the Impedance. Impedance in fact is a more general term, synonymous with resistance for steady currents through metals and simple conductors, but including other quite distinguishable properties when electrolytes are the conductors, or when the current is variable.

After the current has become steady, let the circuit be broken. The galvanometer needle will swing back to zero; but the electrometer needle will swing back only a certain distance, and then continue slowly and more slowly back towards zero. Thus, after the current from the battery has ceased to flow, the electrodes in the electrolytic cell remain at different potentials, and will remain so for a prolonged period. This phenomenon is called the Polarisation of the Electrodes. From being in a state of electrical identity these electrodes have been brought, simply through the agency of a current, into a condition of electrical dissimilarity. In other words, the electrolytic cell has virtually become a voltaic cell; the electrodes have become poles at different potentials.

Let now the polarised cell be joined up in circuit with the galvanometer—i.e. let a wire be set in where the battery at first was. The electrode p being at a higher potential than the electrode q , a current will flow from p to q through the galvanometer, and from q to p through the cell—i.e. in a direction contrary to the direction of the current which first circulated in the circuit. As this current flows, the deflection on the electrometer will rapidly fall off, until very soon the potentials of p and q will be practically equalised, and the current will disappear. Thus, although the polarisation of the electrodes has imparted to the electrolytic cell at first all the virtue of a voltaic cell, this virtue is rapidly lost when it is used as a source of current, for there is nothing to sustain it permanently.

In this polarisation of the electrodes we have one explanation of the increased impedance of the cell. As soon as the current from an external source begins to pass through, decomposition begins in the electrolyte. The ions accumulate on the platinum electrodes, which become coated with oxygen and hydrogen gases. They are no longer platinum, platinum, dipping in an electrolyte; but oxygenised platinum, hydrogenised platinum, dipping in the same. The hydrogenised platinum, which is that by which the original current left the electrolyte (q in fig. 19), behaves like the zinc in an ordinary cell, but behaves like the zinc only so long as it is hydrogenised, and therefore oxidisable. When, then, the polarised electrolytic cell is included in

a circuit otherwise free of electromotive force, a short-lived current will flow at the expense of the electromotive force of polarisation, its energy being derived from the reunion with their appropriate associates in the water molecule of the oxygen and hydrogen clinging to the platinum electrodes.

As we have seen, the electrolysis of dilute sulphuric acid results in the appearance at the electrodes of oxygen and hydrogen. The oxygen is given off where the current enters the electrolyte, and the hydrogen is given off where the current leaves the electrolyte. An obvious and simple experiment will show that the amount of water decomposed in a given time is proportional to the current as measured on the galvanometer. Thus we may compare currents by the quantities of a given electrolyte which they decompose in a given time. Faraday's voltameter, as shown in fig. 20, is intended for this purpose. As compared with a galvanometer, the voltameter has the obvious disadvantage that it cannot measure a current at once,

but only after the current has been flowing for some time. Hence it measures only the average current during this time; so that unless we know the current to be very constant we cannot draw sure conclusions from the indications of the voltameter. When, however, we arrange matters so that the current is steady, we have in electrolysis a convenient means of measuring a current in terms of a quantity of matter decomposed. Not only is the amount of any electrolyte decomposed proportional to the strength of current used, but the amounts of different electrolytes decomposed by the same current have a definite numerical relation to one another—a relation which Faraday showed to have a most essential connection with the known laws of chemical combination.

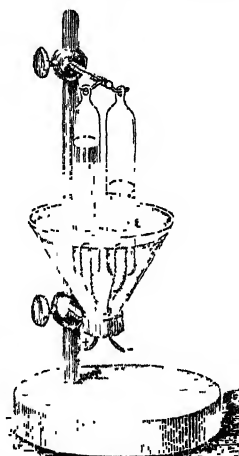

Fig. 20.

Let us take, for example, three electrolytic cells—the first, an ordinary voltameter with dilute sulphuric acid as electrolyte; the second, a V-shaped tube containing fused silver chloride with a silver wire for negative electrode and a piece of carbon for positive electrode; and the third, a solution of sulphate of copper with copper electrodes. Let these electrolytic cells be put in series, and a sufficiently strong current passed through them. In the first—the voltameter—oxygen and hydrogen will collect; in the second, chlorine will appear at the carbon, and may be collected, while silver will be deposited on the silver wire; and in the third, copper will be deposited on the negative electrode, while the positive electrode will gradually dissolve away. After the current has flowed for some time, measure the amounts of gases collected, and the amounts of silver and copper deposited. The last two are easily measured by simply weighing the electrodes before and after the process—the increments of mass of the silver and copper which acted as the negative electrodes in the silver and copper salts respectively giving at once the amounts deposited on them. Suppose, for example, that 2 milligrammes of hydrogen and 16 milligrammes of oxygen have collected in the voltameter; then it will be found that 70.8 milligrammes of chlorine

have collected over and on the carbon, 216 milligrammes of silver have been deposited on the silver, and 63 milligrammes of copper on the copper electrode. Now these numbers measure what are called the chemical equivalents of these substances—they are proportional to the quantities which enter into similar combinations. Thus, in hydrochloric acid, for every 2 grammes of hydrogen there are 70.8 grammes of chlorine; in cupric chloride, for every 70.8 grammes of chlorine there are 63 grammes of copper; and so on, right through all the related compounds of these substances. See ATOMIC THEORY.

During electrolysis the products of decomposition appear only at the electrodes, and nowhere else. The electrolyte consists in fact of two groups of components, chemically bound together everywhere throughout the liquid. But the steady appearance of the ions at the electrodes shows that the two groups of components must be steadily travelling in opposite directions through the electrolyte. Hence it follows that although these molecular groups seem to be chemically bound together everywhere throughout the liquid, the individual component groups are constantly changing their associates. For example, in the case of the electrolysis of fused silver chloride any individual silver molecule is handed on, so to speak, from chlorine molecule to chlorine molecule till it reaches the negative electrode and is deposited there. At the same time, each individual chlorine molecule passes in the other direction from union with one silver molecule to union with the next, until finally it reaches the positive electrode and becomes free—i.e. there is constant dissociation and recombination going on in the substance of the electrolyte. It is now generally believed that in every electrolyte there is always a certain number of free ions at any given instant. The individual ions which are free at one instant are in combination with their oppositely charged associates at another; but on the average there is always a certain number of both kinds of ions free. The feeblest electromotive force is sufficient to compel a certain drift of ions, which we may suppose to be conveying the current of electricity by a kind of convection through the liquid. When the ions reach the electrodes, they no longer find ions of the opposite kind to combine with, and begin to accumulate on the electrodes. But for this a finite electromotive force is necessary; for with the accumulation of ions on the electrodes a reversed electromotive force—the so-called electromotive force of polarisation—begins to show itself. This grows with the accumulation of the ions up to a certain point; and if the external electromotive force is not greater than the electromotive force of polarisation so produced, the current will cease to flow, or at least be so enfeebled as to be practically useless in causing electrolysis.

The ions, as they appear at the electrodes, may not be the real components of the electrolyte which are being urged in opposite directions through the liquid. In the case of fused silver chloride, the ions are no doubt these very components; but in the case of dilute sulphuric acid, we have no right to regard hydrogen and oxygen as the real original products of electrolysis. Indeed, we know by experiment that the purer the water the greater its resistance; so that we have every reason to believe that absolutely pure water is a non-conductor and cannot be electrolysed. Probably the secondary actions which in the case of dilute acid transform the real original ions into oxygen and hydrogen may be somewhat similar to what is certainly part of the action when a solution of sulphate of soda is electrolysed. The components of the molecule Na_2SO_4 are Na_2 and SO_4 —i.e., sodium and what

is called sulphion. The sodium ions drift with the current, the sulphion ions against it. But the sodium ion, when it appears at the negative electrode, gives up its charge and at once acts chemically on the water, forming soda, Na_2O , and liberating hydrogen, H_2 . Again, at the positive electrode, the sulphion, not being able to exist in the free state, breaks up into SO_3 and O ; and then the sulphuric acid is dissolved up in the water, and oxygen is given off. Thus, again, the constituents of water appear as the ions, exactly as in the case of the dilute acid. Here, however, the molecule of the electrolyte is not really Na_2SO_4 , but has so much water united with it. Thus there may be a direct decomposition of water, as well as the sulphate of soda. Whatever the real process of electrolysis, it is certain that in many cases secondary chemical actions quite mask it. These secondary actions do not, however, affect the accuracy of the law of electrolysis. Whatever be the apparent products of decomposition, these, if they can be caught and measured, will appear in quantities proportional to their chemical equivalents. It is further evident that if one electro-chemical equivalent of an electrolyte is decomposed, it must be decomposed into components chemically equivalent to one another and to it. Hence it is enough to measure carefully the electro-chemical equivalent of one of the ions or products of decomposition. By means of a table of chemical equivalents we shall then be able to calculate the electro-chemical equivalents of given electrolytes. So many are the causes, both physical and chemical, which tend to disturb the perfect accumulation of the ions on or over the electrodes that the accurate experimental determination of the electro-chemical equivalent is in certain cases a matter of great difficulty. Large copper electrodes in copper sulphate yield fairly good results; but the only completely satisfactory combination is a particular solution of nitrate of silver with pure silver electrodes. The electrolysis of this electrolyte is accompanied by an accurate transference of so much silver from one electrode to the other. In other words, the one electrode loses as much as the other gains, a degree of perfection which is hardly ever attained in other cases. Recent independent determinations by Kohlrausch and Rayleigh agree to the fourth significant figure; so that we may safely say that the unit of current known as the ampère will reduce out of a solution of nitrate of silver 1.118 milligrammes of silver per second. This, therefore, is the electro-chemical equivalent of silver. Now in chemical combinations 216 grammes of silver correspond to 18 grammes of water and to 65.4 grammes of zinc. Hence a simple calculation gives .0932 milligramme as the electro-chemical equivalent of water, and .3388 milligramme as the electro-chemical equivalent of zinc.

The unit of current which has just been mentioned, the ampère namely, is one-tenth of the electro-magnetic unit of current, which will be discussed farther on. Meanwhile it will be sufficient to indicate experimentally what magnitude of current the ampère is. If an ampère is passing along a conductor of 1 ohm resistance—say a column of mercury 106.3 centimetres long and 1 square millimetre cross-section—the electromotive force along the conductor—i.e. the difference of potential of its ends—will be the quantity known as 1 volt; and the volt is such that the electromotive force of a Daniell cell is about 1.08 volts. In connection with electric lighting, these units—the volt, the ampère, and the ohm—are in universal use.

Intimately connected with electrolysis is the theory of action of the ordinary galvanic or voltaic

cell. For, whenever such cells are being used for the production of electric currents, there are going on within them chemical actions essentially electrolytic. Take, for example, the Daniell cell with its copper and zinc plates dipping respectively in solutions of copper and zinc sulphates. When the cell is closed, the current flows externally from the copper to the zinc, and internally from the zinc through the zinc and copper sulphates to the copper. The electrolysis of these electrolytes is a necessity, with the result that the zinc is gradually dissolved away, and copper deposited on the copper electrode. The net chemical result is the removal of copper from the sulphate and the substitution of an equivalent of zinc. But this chemical reaction is accompanied by the liberation, as heat, of a certain amount of energy. It is this energy which is the source of the electric energy when the replacement of copper by zinc in the sulphate is effected in the particular arrangement known as the Daniell cell. Now, according to Thomsen's determinations of heats of combination, the consumption of 1 gramme of zinc in a Daniell cell means the evolution of 8053 gramme-degrees—i.e. an amount of heat that would raise 8053 grammes of water 1° C. in temperature. Hence the consumption of an electro-chemical equivalent of zinc—i.e. .3388 milligramme—means the evolution of 2.728 gramme-degrees of heat. This, then, is the energy which is associated with the production of one unit of electricity. To reduce it to dynamic units we must multiply by the factor 4.2×10^7 , which is the number of units of energy equivalent to the heat required to raise the temperature of 1 gramme of water 1° C. Thus we find 1.146×10^8 as the energy which a Daniell cell liberates per second when it produces a current of 1 ampère. If E is the electromotive force associated with this unit current, then E measures the work done per second by the current; and assuming that this is the energy liberated in the cell, we find $E = 1.146 \times 10^8$ electro-magnetic (C.G.S.) units of electromotive force—i.e. 1.146 volts, according to the definition of a volt. This is slightly higher than the real value of the electromotive force of a Daniell cell, but it is close enough to warrant the conclusion, first enunciated by Kelvin (1851), that the electromotive force of any electro-chemical apparatus is, in absolute measure, equal to the dynamical equivalent of the chemical action that takes place during the passage of unit current for unit time. There are many cases of galvanic combinations for which this principle fails to a degree which cannot be even approximately referred to errors of experiment. Some other principles, either chemical or physical, must be involved.

We are now able to see why it is that one Daniell cell cannot effect an electrolysis in which the constituents of water appear as the ions. It is simply because the heat developed in the formation of an equivalent of water by direct union of its constituents is about half as great again as the heat evolved in the combustion of an equivalent of zinc in a Daniell cell. Hence to decompose an electro-chemical equivalent of water requires more energy than is supplied by the combustion of an electro-chemical equivalent of zinc in the cell.

The general principle here indicated may be stated thus: A current i flowing through a given electrolyte decomposes i electro-chemical equivalents in unit time. But this requires a definite amount of work done, which we may write ie , where e measures the work which must be done to decompose one electro-chemical equivalent. Hence the energy of the current must be at least ie , or, in other words, e measures in absolute measure the smallest electromotive force with which distinct electrolysis can be effected.

All the phenomena which accompany simple

electrolysis are encountered in the action of galvanic cells. The poles, like the electrodes, become, or tend to become, polarised. This is especially the case in single-fluid cells, in which the apparent electromotive force very markedly diminishes during the first few moments of action, due to the reversed electromotive force of polarisation produced by the accumulation of the ions on the poles. In the so-called constant elements, such as the Daniell, the Bunsen, or the Grove, all of which are double-fluid cells, the ion is either of the same nature as the pole at which it appears, or is dissolved in the fluid so as not to accumulate. By such means the electromotive force is kept fairly constant so long as the strength or characters of the solutions do not greatly alter. The chief conditions to be fulfilled by cells which are to yield strong steady currents are (1) small polarisation, (2) a plentiful supply of electrolyte, (3) a small resistance. This last condition is obtained by using large surfaces for the electrodes, which are opposed to each other as closely as the arrangements of the cell will permit.

The difficulties of measuring the true resistance of electrolytes, and therefore of galvanic cells, have already been touched upon. We must here confine ourselves to the chief results which experiment has established. As compared with metallic conductors, the specific resistance of electrolytes is very great. Then, again, rise of temperature diminishes the resistance of electrolytes, whereas, except for selenium, phosphorus, and carbon, it increases the resistance of simple conductors. Finally, in the case of solutions in water of such compounds as sulphuric acid, nitric acid, sulphates, chlorides, nitrates, and so on, there is in general a definite solution which conducts better than any other solution of the same substance—i.e. a definite percentage composition which is associated with a minimum specific resistance. In all cases a condition of infinite resistance is approximated to as the solution is taken weaker and weaker; and in some instances (sulphuric acid, for example) the same condition of infinite resistance is hinted at for infinitely strong solutions—i.e. for the pure non-hydrated substance.

The polarisation of the electrodes during electrolysis has within the 20th century acquired a great practical importance in connection with the construction of secondary batteries or accumulators. An accumulator is simply a polarised electrolytic cell capable of supplying a steady current for a lengthened time. Theoretically, of course, all polarised electrolytic cells are accumulators; but usually the currents they supply are short-lived and feeble. It was not till 1860 that Planté constructed an accumulator which could supply a really efficient current. The Planté secondary cell is formed by the electrolysis of dilute acid with lead electrodes. With sufficiently strong currents, the result of the electrolysis is that the positive electrode becomes covered with peroxide of lead (PbO_2), while lead accumulates in a spongy form on the negative electrode. When the polarisation has been carried on to a sufficient extent, the cell is said to be charged, and it will be found to have all the properties of a true galvanic cell of low resistance and fairly high electromotive force (about 2 volts). On being closed, it will supply a current sufficient to keep a thin wire glowing for several hours. At the same time, the peroxide of lead will become reduced to a lower oxide, and the spongy lead will be oxidised, while the sulphuric acid present gives rise to other reactions. During the greater part of the discharge of the cell the electromotive force remains very constant, and only begins to diminish as the depolarisation approaches completion. When the

charged cell has thus, through use, lost nearly all its accumulated electrical energy, it is put into circuit with a primary source of current energy and re-charged. The modifications of construction introduced by Faure in 1881 gave a great impulse to the development of accumulators as a practical source of electrical energy. Instead of using merely lead sheets as electrodes, Faure covers them first with a layer of minium or red lead. With these as electrodes the electrolysis of dilute sulphuric acid is effected, the result being, as before, the formation of peroxide of lead at the positive electrode or spongy lead at the negative electrode. Re-charging from a prime source restores the peroxide of lead and the spongy lead as in the first charging. As part of the recent development in electric lighting, the efficiency of accumulators has been greatly increased; and they are now largely used as the direct source of power. A battery of Bunsen or other cells may be used for charging purposes; but if the wasteful voltaic cell had been our only prime source of electric energy, the secondary cell could never have assumed the practical importance it has. It is because we can generate electric energy dynamically and economically that we find a use for the accumulator, which is simply an arrangement for the storage of so much electrical energy in a form convenient for future purposes.

Of all the thermal effects produced by currents, the Joule Effect is the most conspicuous and by far the most important. But there are other thermal effects which are associated with the transference of electricity, and which are readily distinguished from the Joule effect by what is known as their reversible character. Thus the Joule effect always means a rise of temperature in the conductor whatever the direction of the current through it; whereas these so-called reversible effects mean a rise of temperature when the current passes in the one direction, and a fall when it passes in the other. If at any part of a circuit, in which a current is flowing, a fall of temperature is observed, we are probably safe in regarding this cooling effect as one of these reversible effects. We may test this directly by reversing the current; but occasionally the conditions of the experiment may prevent the application of this test. Thus in some cases a galvanic cell, in circuit with a large external resistance, is found to cool. Since the current due to a given galvanic combination must always flow in the same direction through the cell, it is impossible, of course, to apply the test of reversal. Other galvanic cells, again, when similarly joined up with a high external resistance, are found to rise in temperature under conditions in which the true Joule effect is inappreciable. Such thermal effects seem to be true reversible effects; and upon them Helmholtz based his explanation of the apparent failure, in many instances, of Kelvin's dynamical theory of the electromotive force of a battery (see above). In most cases the electromotive force is smaller than what the chemical reactions imply; but in some it is greater. In the former there is intrinsic heating in the cell; in the latter there is cooling—exactly the relations which the principles of energy require. For, as in the latter case, if the electrical energy generated is greater than the chemical energy supplied, it must borrow heat from the surrounding substances to make up its surplus energy. The further fact that those cells, which either heat or cool of themselves, have electromotive forces which vary with temperature points to these being truly reversible thermal effects. An electromotive force which grows with temperature is associated with a cooling effect in the cell as the current is flowing, while an electromotive force which diminishes with rise of temperature is associ-

ated with a heating effect. This must be so; for in all cases of transformations of energy, the final effects react so as to resist the changes that lead to them. We find simple applications of the same dynamic principle of reaction in the other reversible thermal effects of electric currents. These are intimately connected with the subject of thermo-electricity, which we shall now discuss.

Thermo-electricity dates from 1821, when Seebeck discovered that a current was generated in a circuit composed of copper and antimony, when the junctions were at different temperatures. With a sufficiently delicate galvanometer, the same phenomenon may be shown not only with any two different metals, but also with the same metal in two different conditions. Thus a stretched, twisted, or (if possible) magnetised wire will give thermo-electric currents with a piece of the same wire which has not been so treated. Slight impurities cause distinct changes in thermo-electric properties; indeed, thermo-electric currents may often be obtained in a circuit of two wires, which no other physical or even chemical test can differentiate. The fundamental fact of thermo-electricity is that, in a circuit built of two or more different conductors, a current is in general generated when one junction at least differs in temperature from the others. For the sake of definiteness, consider a circuit of the two metals iron and copper, with their junctions at A and B, and with a delicate galvanometer included for the measurement of current. If A and B are at different temperatures, a current will in general be set up in the circuit; and for moderate temperatures up to 250° C. or so, this

current will flow from copper to iron through the warmer junction, and from iron to copper through the colder junction. Now this current i must derive its energy, ei , from some source; and the only source that exists is the heat which is available in virtue of the unequal distribution of temperature. In virtue of thermal conduction and radiation, the tendency is towards an equalisation of temperature, the warmer junction losing heat, and perhaps the colder junction gaining heat. But if this heat is also being partly drawn upon to sustain an electric current, the equalisation of temperature will be hastened because of this transformation into electric energy. Hence we should expect the thermo-electric current to be associated with, at any rate, a cooling effect at the warmer junction. That such an effect really does exist was established experimentally in 1834 by Peltier—hence the name Peltier Effect. He showed that heat is absorbed or evolved at the junction of two different metals across which any current is made to pass; and that if the direction of this current is the same as that of the thermo-electric current that would be produced by heating the junction, the effect is absorption of heat—i.e. cooling; and *vice versa*. Thus, in a copper-iron circuit at moderate temperatures, the thermo-electric current is associated with a cooling effect at the warmer junction, and a heating effect at the colder junction.

The Peltier effect is defined as the heat absorbed by the passage of unit of electricity in the proper direction across the junction; or otherwise, the

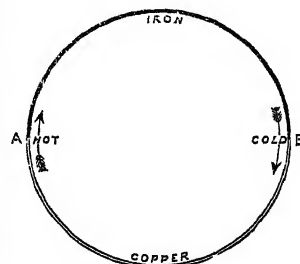

Fig. 21.

heat absorbed per second by the passage of unit current. Let p be the Peltier effect at the warmer junction of a thermo-electric circuit, and p' its value at the other junction. Assuming that the Joule and Peltier effects are the only thermal accompaniments of a thermo-electric current i , we find for the whole amount of heat absorbed the quantity pi , and for the whole amount of heat evolved $p'i + ri^2$, where r is the resistance of the circuit, and where the heats are estimated in dynamic units. If we suppose these to be the only transformations of energy involved, we have at once

$$pi = p'i + ri^2 \text{ or } p - p' = ri.$$

In the latter equation, the difference of the Peltier effects appears as the electromotive force associated with the current i . From this point of view the Peltier effect is to be regarded as an abrupt change of potential at the junction of the two metals.

Thus we may suppose thermo-electric currents to be explained in terms of the Peltier effects, regarded as electromotive forces at the junctions. But the striking phenomenon of thermo-electric inversion, discovered by Cumming in 1823, necessitates, as Kelvin first showed, the supposition of other than Peltier effects for a satisfactory explanation of thermo-electric currents. Take, for example, the copper-iron circuit, keep the one junction B at a steady temperature of, say, 10°C ., and raise the temperature of the other junction A steadily and indefinitely from 10°C . to about a dull red heat. As the temperature of A rises, the current setting from copper to iron through A will increase to a maximum, then decrease to zero, and finally become reversed. The temperature at which this maximum current is obtained is a definite temperature for a given pair of metals, being quite independent of the temperature of the other junction. It is called the Neutral Point. If, within the range of a few degrees, the temperature of the one junction is as much above the neutral temperature as the temperature of the other junction is below it, there is no current. For copper-iron the neutral point is about 275°C .; for zinc-iron, about 210°C .; for cadmium-iron, about 160°C .; and so on. By an application of the second law of Thermo-dynamics, Thomson (Kelvin) in 1851 showed that the existence of the thermo-electric neutral point in the case of two metals like copper and iron required the existence of reversible thermal effects other than the Peltier effect. In this way he was led to the discovery of the Thomson Effect, or the reversible thermal effect which accompanies the passage of an electric current along a wire of varying temperature. For example, when a current passes from cold to hot in copper there is absorption of heat; while heat is evolved if the current passes from hot to cold. On the other hand, for iron, things are just reversed; cooling is associated with the current that flows from hot to cold, and heating with the current that flows from cold to hot. The Thomson effect is said to be positive in copper, and is therefore negative in iron. Cadmium, zinc, silver, gold, nickel between the temperatures of 250°C . and 310°C ., and iron above a dull red heat, have, according to Tait's experiments, their Thomson effects also positive. Platinum, palladium, potassium, sodium, cobalt, nickel below 200° and above 320° , and probably iron again above a bright red heat, are examples of metals having negative Thomson effects. The extraordinary change of sign in the Thomson effect, which Tait discovered to exist both in nickel and iron at certain temperatures, is an extremely interesting phenomenon, and seems to be connected with other properties peculiar to these magnetic metals—such as their loss of magnetic susceptibility and the manner in which their electrical resistances change with temperature.

In comparison with the electromotive forces of voltaic cells, the electromotive forces that can be obtained with thermo-electric circuits are very small. Thus copper-iron with one junction at 275°C ., and the other at 0°C ., has an electromotive force of only '0022 volt. The electromotive force of an iron-nickel pair with junctions at temperatures 0°C . and 200°C . is '008 volt; and the electromotive force of a bismuth-antimony pair with a difference of temperature of 50°C . is about '005 volt. Bismuth and antimony are, because of their high mutual thermo-electromotive force, ordinarily employed in the construction of the thermopile, a valuable instrument for indicating and measuring small variations of temperature. It consists of alternate strips of bismuth and antimony forming a continuous zigzag chain, as indicated in fig. 22. They are arranged in compact form so that the successive junctions alternate, now on this side, now on that side, forming two

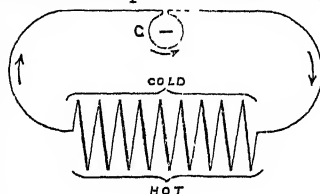

Fig. 22.

plane faces looking opposite ways. If a source of heat is brought opposite to the one face, the junctions ending there are heated by radiation, while the alternating junctions on the other face remain at the temperature of the air.

Returning now to Oersted's discovery of 1820, let us trace the development of electro-magnetism and the closely associated group of phenomena included under the term Magneto-electricity.

Ampère, starting from Oersted's observation of the action of an electric current on a neighbouring magnet, showed that the essential properties of magnets could be demonstrated by means of coils of wire along which currents were passing. In short, every current has associated with it a magnetic field, the distribution of whose lines of force depends on the form of the circuit conveying the current. See MAGNETISM for the simpler illustrations of Ampère's laws. In all cases the lines of force associated with an electric current form closed curves which the current threads. In the neighbourhood of a straight wire conveying a current the lines of force run in concentric circles round the wire. If the wire is curved the lines of force become crushed together on the concave side of the wire and drawn apart on the convex side; and if the wire is made into the form of a closed plane curve—a circle, for example—every line of force will pass perpendicularly across the plane space within the circle. The one which passes through the centre will be straight, and will pass to infinity along the axis of symmetry. All the others will form closed curves embracing the circuit, those which pass nearer to the centre within the circle extending to farther distances in the space outside. Such a circular circuit is, in fact, the nucleus of a magnetic field, which at distances great compared to the diameter of the circle is very similar to the field associated with a bar magnet set at the centre of the circle and perpendicular to its plane. Ampère proved that a small plane circuit was, as regards its magnetic effect at distant points, identical with a small magnet whose magnetic moment was proportional to the product of the area of the circuit and the strength of current flowing round it. If we place ourselves in front of the circuit so that the current appears to be flowing clockwise round it, the northern magnetic aspect of the circuit is on the farther side.

Ampère also showed that the magnetic effect of a closed circuit conveying a current could be calculated according to the following rule. Each small element, ds , of the circuit, with current C flowing through it, may be supposed to produce at a point distant r from the element, and lying in a direction making angle θ with the element, a magnetic force which is equal to $Cds \sin \theta/r^2$, and acts in a direction perpendicular to the plane containing r and ds . The vector sum of all the forces due to the elements which build up the circuit is

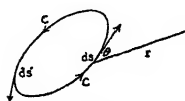

Fig. 23.

is to remember that the lines of force due to a straight current circulate right-handedly with reference to the direction of the current. In the figure the force due to Cds is towards the farther side of the paper, and that due to Cds' is towards the nearer side.

Let us apply the rule to find the magnetic force due to a circular circuit at any point in its axis of symmetry. Let the circle be perpendicular

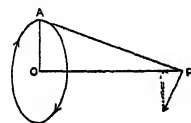

Fig. 24.

to the plane of the paper, and let OP be the axis of symmetry. Let us suppose further that, as viewed from P , the current C in the circuit is circulating clockwise. According to Ampère's rule the magnetic force at P

due to the element at A is

$$\frac{Cds}{AP^2} \frac{OA}{AP} = \frac{Cds a}{r^3}.$$

perpendicular to AP , and since the element itself is perpendicular to AP so that $\sin \theta$ equals unity, the value of the force is Cds/AP^2 , and the component of this along PO , where O is the centre of the circle, is

Every element of equal length will give the same value of the force. Hence the whole force along PO due to the whole circuit is $2\pi Ca^2/r^3$. The components of the forces at right angles to PO obviously balance; hence $2\pi Ca^2/r^3$ is the measure of total resultant force. The force at O , the centre of the circle, is $2\pi Ca^2/a^3 = 2\pi C/a$. Thus the unit current flowing in a circular circuit of unit radius will produce a magnetic field of value 2π or 6.2832 at its centre. We are thus able to measure currents in terms of the same units in which we express magnetic forces. The unit of current just defined is called the electro-magnetic unit. Its value depends on the definition of magnetic force, and may be regarded as based upon the law that two magnetic poles of strength m and m' repel each other with the dynamic force mm'/r^2 , where r is the distance between the poles. More generally in a medium of magnetic permeability μ the law of force is $mm'/\mu r^2$. See MAGNETISM.

As already stated, the electrostatic unit of charge is defined in terms of the law of force ee'/r^2 ; and the electrostatic unit of current will be the current produced when unit charge passes in unit time. There are thus two distinct ways of defining units of current and of charge—viz. the electro-magnetic and the electro-static. When a given current is measured in both units, it is found that the electro-magnetic unit of charge contains a very large number of electrostatic units of charge, and that this number is identical with the number which measures the velocity of light. For example, if the

fundamental units are the centimetre, gramme, and second, and if the electro-magnetic and electrostatic units are expressed in terms of these fundamental units, then it is found that the electro-magnetic unit contains almost exactly 300 million electrostatic units. Now 300 million centimetres or 300,000 kilometres per second is very approximately the velocity of light.

There are various experimental methods for determining this ratio of the two units. It will suffice to indicate one of the simplest in theory. Let a condenser of known capacity K be charged to potential V , both numbers being given in electrostatic measure; and let this charge KV be discharged through a galvanometer of suitable type producing a deflection of measurable magnitude. If the electro-magnetic constant of the galvanometer is known—i.e. the magnetic field produced in its heart when unit current flows through it—the charge KV can be expressed in electro-magnetic measure. The number so obtained divided by the electrostatic measure KV gives the ratio required. This conclusion that the ratio of the two units of electric charge is the velocity of light was one of the foundations on which Maxwell built his brilliant hypothesis that light is an electro-magnetic phenomenon. We shall return to this farther on.

The action between an electric current and a magnet is mutual. When the coil is fixed, as in the earlier forms of galvanometer, the magnet moves. But it is sometimes more convenient to allow the coil to move and keep the magnet on the magnetic field fixed. Thus in Ampère's electro-dynamometer the magnetic field is established in the heart of a fixed coil, within which is suspended a movable coil capable of turning about a vertical axis. The coils are arranged with their axes at right angles to one another. The same current is then passed through both, and the strength of the current measured in terms of the deflection of the movable coil, the turning effect of the magnetic field being balanced by the torque due to the bifilar suspension of the movable coil. Kelvin's Ampère Balance is constructed on the same principle, the main difference being that the electro-magnetic action on the movable coil is balanced by the couple due to a weight which can be slid along a horizontal lever suitably graduated.

In his Siphon Recorder for recording telegraphic signals along the first Atlantic cable, Kelvin used as his galvanometer a light coil suspended in the strong field between the opposing poles of a powerful magnet. The axis of the coil was adjusted at right angles to the magnetic lines of force. When a small current was passed through the coil, the coil at once responded by a rotation to one side or the other according to the direction of the current. D'Arsonval's galvanometer is constructed on exactly the same lines, the movable part being a light coil set in a strong magnetic field.

In all such cases each element of the current may be regarded as acted on by a force which drives it in a direction perpendicular to the current and to the lines of force of the magnetic field in which it lies. We may calculate the whole force acting on a circuit placed in a magnetic field by supposing that each element Cds is acted on by a force equal to $CdsH \sin \theta$, where H is the magnetic force at the region occupied by Cds , and θ is the angle between Cds and H . The direction in which Cds is urged has the same relation to the rotation by which Cds may be made to lie along H as forward motion has to the clockwise rotation of a right-handed screw. This rule can be easily deduced from the equivalent statement that parallel currents attract each other and oppositely directed currents repel.

Let a vertical wire hang within the air-gap of a powerful electro-magnet, and let it be connected up

so as to become when desired a part of a circuit conveying an electric current. When the current is allowed to pass, the portion of the wire in the strong field will be driven at right angles to the lines of force and parallel to the opposed faces of the poles of the electro-magnet. By an ingenious arrangement in which the electro-magnetic force urging the wire to the side was balanced by gravitational forces brought into play by the motion of the wire, Kelvin showed how to measure powerful magnetic fields when a known current was passed along the wire. Conversely, when the field is known the displacement of the wire will be a measure of the current. This is the principle of the String Galvanometer, which is much used in physiological investigations.

In 1831, six years after Ampère had presented to the world the complete theory of electro-magnetism, Faraday made the discovery which opened up the vast realm of magneto-electricity—i.e. the production of electric currents by magnetic changes. In 1847 Helmholtz showed that the fundamental fact of magneto-electricity could be deduced as an illustration of the Conservation of Energy from the facts of electro-magnetism.

Imagine a closed plane circuit conveying a current to be set with its plane parallel to the lines of force of a magnetic field, and let it be capable of free rotation about an axis perpendicular to the lines of force. If left to itself the circuit under the influence of the electro-magnetic force will at once begin to turn so as to set its plane perpendicular to the magnetic field. It will swing round towards this position with increasing kinetic energy. To account for the energy we must assume either that the voltaic cell or other original source of electromotive force is drawn upon more briskly while the circuit is moving, or that the current itself is diminished in intensity as the circuit swings round. It is the latter supposition which falls in line with Faraday's discovery. With a sufficiently sensitive galvanometer included in the circuit this fall off may be observed. Not only so, but if the circuit contains no original source of electromotive force, and if it is then moved mechanically from parallelism with the lines of force towards the position of perpendicularity, a current will be observed to flow in the circuit while the change is being made. This current is called an induced current, and exists only while the number of lines of magnetic force which pass through the circuit is altering.

Change in the magnetic field relatively to a circuit may be made in a variety of ways—e.g. by approach of a magnet with one pole nearer to the circuit than the other, by withdrawal of the magnet again, by approach or withdrawal of the circuit from a pole of a magnet, by starting a current in a neighbouring coil and so establishing a magnetic field in the region occupied by the circuit, by suitably moving the circuit in the neighbourhood of a coil carrying a current, and so on. In all such cases the induced current is sustained by an electromotive force which at each instant is equal to the rate of change in the number of lines of magnetic force included by the circuit.

In many practical applications the magnetic change is made to take place abruptly, and what we obtain is a rapidly varying electromotive force which within a very short time rises to a pronounced maximum and falls off to zero. The result is a correspondingly short-lived electric flux or discharge of electricity round the circuit, the measure of the flux being the ratio of the total change in the number of lines of force embraced by the circuit to the resistance of the circuit. What is considered here directly is not the electromotive force, but the successive values of the rapidly changing electro-

motive force summed up through a short interval of time. Following the analogy in dynamics, we may call this time-integral of the electromotive force the electromotive impulse. Then, just as the electromotive force is numerically equal to the product of the resistance and the current, so the electromotive impulse is numerically equal to the product of the resistance and the electric flux.

The electric flux may be measured experimentally by means of a ballistic galvanometer or a flux-meter. In the most familiar form of ballistic galvanometer a slow-swinging magnetic needle is suspended, as free as possible from retarding forces, in the heart of a closely wound coil. When a short-lived electric flux passes round the coil the momentary magnetic field acts on the needle and gives it a sudden rotation about its suspending fibre. Before the needle has appreciably left its original position of equilibrium the acting magnetic field has ceased, and the needle swings to a limiting position through an angle in terms of which the magnetic impulse can be expressed. The needle immediately swings back again towards and through the zero position.

In Gassiot's form of flux-meter the D'Arsonval type of galvanometer is made use of. The delicately suspended rectangular coil moves with its vertical strands in the air-gaps formed between a central cylinder of soft iron and the concentrically shaped poles of a strong magnet. The arrangement is illustrated diagrammatically in fig. 25, in which the central pillar of iron is shown by a circle embraced by the semicircular lines representing the poles. The straight lines drawn diametrically across the central pillar represent the upper horizontal strands of the coil whose vertical strands pass down through the air-gaps on each side. The mechanical details of the suspension of the coil need not be considered here, as all we aim at is the illustration of electro-magnetic and magneto-electric theory.

When a current flows along the vertical strands, downwards in one and upwards in the other, the electro-magnetic forces generated will act on the vertical strands and drive the whole coil round in one or other direction. On the other hand, if no current is flowing at first in the coil, and if the coil is compelled by some external means to move round the axis of suspension, an induced current is at once produced in the coil due to the fact that the vertical strands are cutting across the lines of force. In accordance with the general law of energy, this induced current is opposite in sense to the current which if supplied to the coil would make the coil rotate in the same direction. Hence the electro-magnetic action of the induced current is such as to resist the motion which has generated it; and very quickly the coil is brought to rest. In virtue of this damping action automatically produced by the coil moving in the magnetic field, there is nothing resembling the free swinging about a position of equilibrium such as characterises the motion of the needle in the earlier form of ballistic galvanometer. The greater the angular momentum with which the suspended coil is started, the further will it rotate before the damping action of the induced current brings it to rest. This initial angular momentum is proportional to the electric flux which has passed momentarily through the coil. Before the coil has well started the original electric flux has ceased to flow; but the coil continues to swing round, cutting across the lines of force. The induced currents generated by this motion react upon the coil, which is quickly brought to rest after being deflected through an angle determined

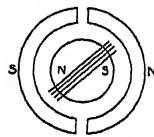

Fig. 25.

by the initial angular momentum—i.e. by the original electric flux. From that position the coil slowly creeps back towards the true zero, being retarded by induced currents generated by the motion.

Some of the phenomena just described illustrate what is known as Lenz's Law—viz. that the electro-magnetic effect of the induced current resists the magnetic change which has produced the current. Thus, when a magnet is made to approach end on towards a coil, the current induced in the coil will be such as to repel the nearer end of the magnet. On withdrawal of the magnet, the induced current will flow round the circuit so as to attract the nearer end. Again, let us place two coils close together, say the one lying within the other, and let matters be so arranged that a current may at will be sent through one of them. Then, at the instant at which this current begins to flow in what is known as the primary circuit, an associated magnetic field is generated, and round the other or secondary coil an electromotive impulse will act equal to the change in the number of magnetic lines of force included in the circuit. The electric flux accompanying the creation of this electromotive impulse will set round the secondary circuit in a direction opposed to that of the current in the primary circuit. The secondary current lasts only during the process of change, and is practically instantaneous, vanishing as soon as the primary current becomes steady. If now the primary circuit is made discontinuous, so that the circuit ceases to flow round the circuit, the associated magnetic field vanishes, and there acts round the secondary circuit an electromotive impulse equal and opposite to the electromotive impulse which acted when the primary current was established. This is the principle of the Induction Coil (q.v.), an indispensable piece of apparatus in the study of the effects of induced currents.

An ordinary galvanometer included in the secondary circuit will show equal and opposite deflections when the primary is first made and then broken. When the primary current is established and broken in rapid alternation, these equal and opposite induction fluxes will follow each other so rapidly that the galvanometer needle will remain practically unaffected. There will be an initial temporary deflection accomplishing the first establishing of the primary, and an equal and opposite temporary deflection when the current is finally broken; but no definite deflection between times, simply because the rapidly alternating induced fluxes balance as regards their effect on the galvanometer needle.

When the secondary circuit is not completely closed by a continuous chain of conductors, but is interrupted by an air-gap, a different set of phenomena will be observed. Provided the field established by the primary is strong enough, an electric spark will pass across the air-gap at the instant at which the primary current is broken; but no spark will be observed at the instant the primary circuit is made. Thus when, by means of an interrupter such as is familiar in most forms of induction coil, the primary current automatically makes and breaks itself in rapid alternation, the sparks across the air-gap occur in rapid succession, but only at the instants of the breaking of the primary. The reason for this may be briefly expressed as follows. Before a spark can pass in air, the electrodes which are the opposing ends of the secondary circuit must be at a definite difference of potential, whose value depends on the length of the air-gap, the forms and condition of the opposing conducting surfaces, and the pressure of the air. This necessary minimum difference of potential is produced by the variation in the magnetic field, and only when this

variation is sufficiently rapid will the accompanying electromotive force attain a high enough value to produce the spark. Consider now the typical arrangement of primary and secondary coils as shown in fig. 26. The more nearly coincident the secondary coil is with the primary, the greater will be the electric flux induced in the secondary for a given electric current in the primary; and at the make of the primary the induced current in the secondary sets round in the opposite direction. But a similar induction takes place in the primary itself at the instant the current is started; and its effect as observed is to retard the growth of the primary current, which takes a short but finite and measurable time to attain its full value.

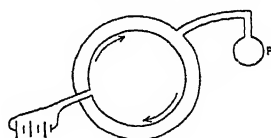

Fig. 26.

On the other hand, when the primary current is broken the interval of time during which the magnetic change takes place is much shorter than when the current is being established, the rate of change attains a higher value at some moment of this interval, and the corresponding induced electromotive force reaches a higher momentary intensity. The electromotive impulse round a closed secondary circuit has the same value at make and at break of the primary; but at the break the impulse goes through its successive values more quickly, and therefore touches a higher value of electromotive force. Consequently when an air-gap is introduced the greater intensity reached by the electromotive force at the more abrupt break is able to overcome the insulating power of the air. This at the more gradual make of the primary the induced electromotive force is unable to do.

The self-induced electromotive force when a current is being established in a coil is evidenced simply in the retardation of the growth of the current to its final steady value. But when the continuity of the circuit is broken and the current is made to cease, the self-induced current at break shows itself as a distinct spark at the point where the circuit is broken. Should an iron-cored electro-magnet be included in the circuit, so that the lines of magnetic induction are greatly increased, the self-induced spark becomes correspondingly intense. This self-induced flux, or 'extra current,' as it is sometimes called, establishes a momentary magnetic field within the circuit at the very instant the original field due to the steady current is disappearing with that steady current. But this rapid rise-and-fall in the magnetic field does not affect the total value of the induced electromotive impulse round a neighbouring secondary circuit. It affects the law of progression in the successive values of the electromotive force which build up the impulse. The value of the electromotive impulse which produces a spark across the air-gap of an interrupted secondary circuit depends entirely upon, and is numerically equal to, the number of lines of magnetic induction which have disappeared on the breaking of the primary circuit. But the form of the discharge depends on the other electrical properties of the circuit—viz. its resistance, capacity, and self-inductance. This last-named quantity is measured by the number of lines of magnetic force included in the circuit when unit current flows round it. A similar quantity is the mutual inductance of two circuits, which is measured by the number of lines of force established within one of the circuits when unit current flows round the other. These coefficients of self and mutual in-

duction depend entirely upon the geometrical forms and relative positions of the two circuits.

To illustrate how the form of the discharge depends on the various electrical constants of the circuit, it will suffice to describe the simplest case, first worked out by Kelvin, then Professor William Thomson, in 1853. He showed that under certain conditions the discharge of a charged Leyden jar or other condenser was periodic. That is to say, the original potential difference between the two coatings does not simply fall off to zero in a continuous flux in the same direction like a flow of water from a lake to the sea-level. On the contrary, the discharge comes with such a rush that it overshoots the zero-mark, like a pendulum swinging past its lowest position. After a short but measurable interval of time the coating at first positive becomes negatively charged, and the coating at first negative becomes positively charged. The difference of potential, in short, changes sign, reaches a maximum in the other direction, and then discharges the Leyden jar back again towards the original state of matters.

Suppose we have a U-shaped tube with a stop-cock at the bend which we may open or shut at will. Let it first be shut, and let water be poured into the one limb. When the stop-cock is opened the water will rush through and begin to fill the other limb. The levels of the water in the two limbs will rapidly approach equality, but because of the momentum of the moving water the equality of level will be overshoot, and the water will not come to rest in the U-tube until after a few oscillations of level in each limb. This is analogous to a periodic oscillatory discharge. If, however, we use glycerine instead of water in the U-tube and carry out the same experiment, the equality of level will be reached without any appreciable oscillation. The glycerine, on account of its viscosity, will gradually and with increasing slowness fill up the originally empty limb after the stop-cock is opened. This is analogous to an aperiodic discharge.

In this hydrokinetic experiment we see that the character of the motion which follows a disturbance is fundamentally influenced by the physical properties of the fluid, the motion being periodic or aperiodic according as the viscosity is small or great. Similarly the discharge of a condenser may be oscillatory and periodic or non-oscillatory and aperiodic according to the electrical constants of the condenser and the associated conductors. As Kelvin first showed, when a condenser of capacity C is discharged through a coil of resistance R and self-inductance L , the period of the oscillatory discharge is given by the expression,

$$2\pi \sqrt{\frac{1}{LC} - \frac{R^2}{4L^2}} = \frac{4\pi L}{\sqrt{4LC - R^2}}$$

When the quantities C, R, L are such that the expression under the square-root is negative, the period becomes imaginary, and the discharge is non-oscillatory. That is, when R^2 is not less than $4L/C$ the discharge is aperiodic, and the potential difference between the two coatings of the condenser or Leyden jar diminishes continuously towards zero. But when R^2 is less than $4L/C$ the discharge is oscillatory and the period is given by the expression shown above. Suppose, for example, that the condenser is a Leyden jar, and that the internal coating is positively charged. Then after half the periodic time measured by the formula the inner coating will have acquired a negative charge, in another half-period a positive charge, and so on. While this alternation in sign of the opposite charges on the two coatings is proceeding the amount of the difference of potential at every half-period diminishes. In other words, the discharge is oscillatory with rapidly diminishing amplitude.

We have seen how Maxwell, led by various considerations, came to the conclusion that light was an electro-magnetic phenomenon, transmitted as a vibratory motion through the ether. If this hypothesis be correct, it should be possible to obtain electro-magnetic waves differing from light waves only in their wave-length and periodic time. The practical realisation of this, first distinctly suggested by Fitzgerald, and shortly afterwards brilliantly carried out by Hertz, depends upon the theory of the periodic discharge which has just been explained. Not only did Hertz construct a convenient vibrator, but he solved the problem of constructing what might be termed an 'electric eye'—i.e. a form of apparatus sensitive to the influence of electro-magnetic waves. Knowing what the period of his vibrator was, he formed a simple circular circuit with a tiny air-gap, which for electro-magnetic variations had the same period as the discharge of the vibrator. In other words, the receiver or detector was 'in tune' with the vibrator; and, in accordance with the principles of resonance, when the receiver was placed suitably in the line of propagation of the electric disturbance it responded to these by showing small sparks across the tiny air-gap.

Hertz's early form of detector was soon superseded by more delicate forms, the most familiar being of the type which Oliver Lodge called 'coherer.' It was discovered by Branly that the electrical resistance of a column of metallic filings loosely pressed together becomes greatly diminished when electro-magnetic radiation falls upon it. To restore the original resistance of the column it is sufficient to shake the filings. When the coherer forms part of a circuit which includes a galvanometer and battery, the arrival of an appropriate electro-magnetic disturbance diminishes the resistance of the coherer, causing a greatly increased current in the coherer circuit, with a corresponding increase in the galvanometer deflection.

By use of the coherer or other delicate detector many of the results obtained with considerable difficulty by Hertz can be readily demonstrated, such as the reflection and refraction of electro-magnetic waves, their polarisation, and the speed of their propagation. In these respects they behave in practically the same way as waves of light; and thus the physical similarity of the two kinds of wave motion, the optical and the electrical, is practically established.

The vibrator is an arrangement of small capacity attached to the secondary coil of an induction coil. The spherical knobs of the vibrator are brought to a suitable distance from each other, and across this air-gap the secondary circuit of the induction coil is discharged. The primary circuit is provided with an automatic make and break, the result being that a torrent of sparks passes across the air-gap. But every spark is an oscillatory discharge, whose period is practically determined by the expression $2\pi/LC$, the term $R^2/4L^2$ being made negligible in comparison with $1/LC$. Each spark is therefore the source of a short succession of electric waves which are propagated through space. If these waves reach in sufficient intensity the position of a coherer suitably arranged in circuit with battery and galvanometer, the coherer will show their presence by momentarily increasing in its conductance and allowing a current to pass through a galvanometer or other instrument for indicating its presence. This is, in fact, the basis of the method of wireless telegraphy, which Marconi and others have developed with great success during recent years; see TELEGRAPH.

One of the most important uses of the induction coil is to produce electrical discharge in air or other gases at greatly reduced pressures; see VACUUM TUBE and RÖNTGEN RAYS. The remarkable pheno-

mena associated with electric discharge through vacuum tubes have been to a large extent successfully co-ordinated in terms of the modern electron theory. The underlying hypothesis of this theory is that electricity consists of distinct charges associated definitely with particles or corpuscles. Of these some are charged negatively, some positively, being distinguished as negative and positive electrons respectively. It has been found possible to co-ordinate many phenomena on the assumption that each electron is the nucleus of an electric field in virtue of its charge, and a magnetic field in virtue of its motion. Any electron in motion will be influenced by both the electric force and the magnetic force at the point of space occupied. Broadly stated, the interaction between moving electrons and magnetic fields is the same as that between current elements and magnetic fields according to the laws established by Ampère.

We pass from the case of the current elements to that of moving charges by substituting for the element Cds the product, ev , of the charge e into its speed v . Thus the magnetic force at distance r due to the electron is $ev \sin\theta/r^2$, where θ is the angle between r and the direction of motion of the electron. Also the electro-magnetic force acting on the electron when placed in a magnetic field, in which ϕ represents the angle between the magnetic force H and the velocity of the electron, is $evH \sin\phi$, driving the electron at right angles to the magnetic force and to the direction of motion of the electron.

In the electron the charge e is associated with a mass m ; and any force acting on the charge e will produce an acceleration depending also on this mass.

These three connected quantities, the charge of the electron, its velocity, and its mass, are linked together by electric and magnetic relations, from which it has been found possible to estimate their values. To show how this may be done, consider the case of a discharge through a gas at very low pressure, such as may be obtained in a Crookes's vacuum tube. The experiments to be described prove that the cathode rays may be regarded as consisting of streams of negatively electrified particles discharged from the cathode through the enlarged dark space. Their average straight course through this space is indicated by the position of the fluorescent patch, ab , on the wall of the vacuum tube where the particles impinge. Now if this stream of electrified particles is subjected to a

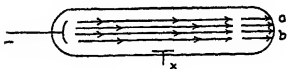

Fig. 27.

transverse electric field or to a transverse magnetic field, the fluorescent patch shifts its position, indicating a deflection of the cathode rays. The direction of this deflection under either of the applied fields named is such as would occur if the cathode rays were composed of negatively electrified particles. There seems to be, indeed, no escape from the conclusion that these rays consist of negative electrons repelled from the cathode with high velocities. The velocities are not all the same; for it is observed that when there is deflection the fluorescent patch becomes more extended than when there is no deflection. This is immediately explained by the consideration that under the influence of a transverse electric or magnetic force of given magnitude the more quickly moving particles suffer less deflection.

Let us suppose that the cathode rays are projected horizontally from left to right, and that two insulated plates are placed in the tube, the one above and the other below the stream of cathode rays. When these are brought to different potentials, the upper plate being, say, at the higher

potential, a downward electric force, F , will be established. The upward action of this electric force upon a negative electron of charge, e , will be F_e .

Now apply a magnetic field by means of opposing poles of a strong electro-magnet placed the one in front of, and the other behind, the vacuum tube. The magnetic lines of force will pass horizontally across the cathode rays, and if suitably directed will deflect them downwards. The value of the deflecting force on each electron will be Hev . By proper adjustment of the vertical electric field, F , and the transverse horizontal magnetic field, H , we may obtain a balancing between the effects of these forces, in which case we shall have

$$Fe = Hev, \text{ or } v = F/H.$$

The balancing will be indicated by the non-existence of any deflection of the fluorescent patch or of either limit of it. By such experiments the velocity of the electrons constituting the cathode rays has been proved to vary from about 20,000 to 50,000 kilometres per second, or, on the average, about one-tenth of the velocity of light.

The velocity, v , having been determined, it becomes a comparatively easy matter to measure the ratio of the charge to the associated mass in each electron—i.e. e/m . This is done by measuring the deflection under the influence of only one of the fields, either the electric or the magnetic. The more convenient force to use is the magnetic, for not only is it more easily sustained, but it can be measured with greater accuracy than is possible in the case of the electric field.

Let the magnetic force act horizontally and transversely on the horizontal stream of electrons. The acting force Hev is always at right angles to the direction of motion, and must equal the centrifugal force mv^2/r , where r is the radius of the circular path which will be described by each electron if the speed is not changing. Hence

$$mv^2/r = Hev, \text{ or } e/m = v/Hr.$$

The radius r is determined by measurement of the deflection D in a distance x , being given to a sufficient approximation by $r = x^2/2D$. See fig. 28.

Thus v , H , and v being known, the ratio e/m is determined. In the case of a cathode discharge in a rarefied gas, this ratio e/m is found to remain practically the same whatever the nature or pressure of the gas, although the speed v may, as noted above, vary within fairly wide limits. Expressed in electro-magnetic units, the value of e/m is about 18 million.

By such experiments we realise that the dark space round the cathode is filled with streams of negative electrons projected from the cathode with velocities varying from a sixteenth to a sixth of the velocity of light.

Let us now consider the behaviour of the positive electrons. From the analogy of electrolysis we should expect them to be moving from the anode towards the cathode. The most effective method of demonstrating their presence is to provide an escape for the positive electrons by a fine channel which perforates the cathode and passes back behind it. The experiments are difficult to make, and the results are complex and not easy of interpretation. But the one undoubted fact is clearly established that the speed of the positive electron is much less than that of the negative electron. The ratio e/m for the positive electrons has many values, with a superior limit of 10,000. Since the charges on the negative and positive electrons are equal and opposite, it follows that the mass associated with the

Fig. 28.

positive electron is at least 1800 times the mass associated with the negative electron.

It has been noted that in kathode discharge the ratio e/m has much the same value for the negative electron, whatever the nature of the gas filling the vacuum tube. It is quite otherwise with the positive electrons. For them the ratio e/m varies through wide limits, and depends upon the nature of the gas through which the discharge is passing. The electric discharge through gases may be compared with the process of electrolysis in liquid conductors. In the latter case the complex molecule is split into two ions, the positive and the negative, which travel in opposite directions through the liquid, and which convey the charges that constitute the current. In electric discharge through gases, the molecule of the gas is dissociated into a negative electron having a small mass and a positive electron whose mass is very slightly less than the mass of the original undissociated molecule. These move in opposite directions in the electric field between the electrodes. Under the influence of the electric force in the neighbourhood of the kathode, the negative electrons, in virtue of their small mass, acquire a high velocity; and on the average the velocities acquired by the positive and negative electrons in the same electric field will be in opposite directions, and will be approximately inversely as the associated masses. This conception gives a general explanation of the broad features of the phenomenon of the electric discharge through gases, but there are many subsidiary features which are not easy of co-ordination in terms of the simpler forms of the electron theory.

According to the view here presented, it is not the gas itself which conducts electricity. The discharge through a vacuum tube is really an electric convection, and the whole evidence goes to show that the negative electron is the important and unchanging agent. Each negative electron carries the same electric charge, and has the same associated mass—so long, at any rate, as the velocities are not too great. In order to measure this charge, e , on each electron, we must in some way estimate the number of electrons, n , which are involved in transferring a measured total charge, ne , to a suitably arranged conductor.

Now electrons may be produced by other means than by electric discharge through gases. For example, the Röntgen Rays (q.v.), which originate at the glass wall of a vacuum tube as a result of the impacts of the electrons, have the property of producing electrons in the air through which they are passing. The Röntgen rays, by their action on a non-dissociated or neutral molecule of a gas, causes dissociation, and the gas becomes what is called 'ionised'—i.e. filled with electrons which make the gas act like a conductor. When a charged gold-leaf electroscope is placed in this ionised gas it rapidly loses its charge, whether that charge be positive or negative. The charged electroscope attracts towards it electrons of opposite charge, and the mating of these opposite charges produces a state of neutrality.

Having in this way ionised a mass of air, Sir J. J. Thomson caused the positive electrons to be attracted towards a conductor having a known negative charge. The diminution of the charge gave the measure of the total charge on the positive electrons. The negative electrons left in the air had therefore a total charge of the same numerical value. This determined the product ne .

In order to measure n , the number of electrons present, Sir J. J. Thomson made use of an ingenious modification of the method of dust-counting as employed by Dr John Aitken. In his well-known experiments on the formation of clouds,

Aitken proved that in saturated air which is being slightly cooled, say, by expansion in an air-pump receiver, fogs are formed by the water condensing as small drops on dust particles; and he showed how the number of dust particles in a cubic centimetre of air could be measured by counting the drops collected on a glass surface. When no dust particles exist in the air, the cooling is unaccompanied by the formation of fog. At a later date, however, C. T. R. Wilson showed that when the cooling is sudden and considerable, fogs may again be produced in dustless air, but only when the air is ionised. In other words, electrons act as nuclei, round which small drops of water condense in saturated pure air when the air is cooled by a sudden expansion. Each drop of water, as soon as it is formed round an electron, begins to fall, soon attaining what is called its limiting terminal velocity when the weight of the drop is just balanced by the resistance of the air. Now Stokes showed long ago how the size of the drop could be measured in terms of this terminal speed; and Sir J. J. Thomson, by observing the rate of descent of the upper part of the cloud formed in the negatively ionised air enclosed in a vessel and cooled sufficiently by expansion, was able to calculate the size of the drops. But the whole amount of vapour changed into liquid could be estimated from the fall in temperature of the saturated air. Hence the number of the drops became known, being simply the ratio of the whole amount of condensed vapour to the size of each drop; and since each drop corresponded to one electron, the number of the electrons also became known.

Thus the number of electrons being known and the whole charge ne , the value of e , the charge on each electron, is also determined. It is found that the negative electron has the same charge whether it is derived from ionised air, hydrogen, oxygen, or carbonic acid. Not only so, but it is the same value of charge as that found associated with the negative electron in the kathode rays and with a hydrogen atom obtained by electrolysis—i.e. 3.4×10^{-10} in electro-magnetic units.

As already noted, the assumptions are that an electron is the centre of a field of electric force, and, when in motion, the nucleus of a field of magnetic force. As the electron moves it carries its own electric field with it; and we may suppose that the motion of the lines of force generates at each point a magnetic force, and with the magnetic field so generated in the region surrounding the moving electron will be associated part of the energy. This may be compared to the hydrodynamic case, in which a body moving through a frictionless fluid transfers kinetic energy to the fluid in such a manner that the whole kinetic energy of the system may be expressed in the form $(m+m')v^2/2$, where m is the mass of the body, and m' an additional mass depending on the density of the fluid and the form of the body.

Now a similar expression can be obtained for the kinetic energy associated with a small charged particle in motion, and the additional mass m' is found to depend on the velocity of the charged particle as well as upon the charge. Thus part of the apparent mass of an electron in motion is electro-magnetic in its origin, and possibly the whole mass may be so. In 1881, before the modern electron theory had been imagined, Sir J. J. Thomson proved that a charged body in motion experienced an apparent increase of mass, and that this apparent mass increased indefinitely as the velocity approached that of light. The velocity of light was therefore the highest possible limit to the velocity of a charged body.

These views have received corroboration from

the study of the values of e/m in the case of electrons moving with higher speeds than can be acquired in the dark space round the cathode of a vacuum tube. Such swiftly moving particles of small mass constitute the β -rays which are shot out from radium with velocities approaching that of light. They may be studied in the same way as the electrons which constitute the cathode rays—i.e. by measuring the deflection in a transverse electric or magnetic field. As first observed by Kaufmann, the ratio e/m diminishes by about one-half as the velocity increases from 240,000 to 280,000 kilometres per second.

As proved by the direction of their deflection in an electric field, these β -rays of high velocity consist of negatively charged particles. The α -rays, on the other hand, consist of positively charged particles which are also projected with high velocities. The so-called γ -rays, again, suffer no deflection in an electric or magnetic field. They seem to be identical with the Röntgen rays, which under certain circumstances coexist with the streams of rapidly moving particles. In the β -rays, then, we recognise the same electrons as those which constitute the cathode rays. For velocities which do not approach close to the velocity of light, the ratio e/m is practically the same for all negative electrons; but when the velocity approaches that of light—and β -ray particles have been observed with a velocity of 290,000 kilometres per second—the ratio e/m markedly diminishes. This can only be on account of the increase in the virtual mass. The distribution of energy in the electro-magnetic field shows that this increase has an electro-magnetic origin, and for rapidly moving electrons the greater part of the mass has this character.

The mechanism of the radium atom which enables it to project with high velocities an apparently endless stream of electrons has not yet been clearly imagined; but the effect of all radio-active bodies on the surrounding gas is the same—they ionise the gas so that it becomes conducting. This ionisation may be explained as due to the collision of the swiftly moving particles emitted by the radio-active body with the molecules of the gas which thus undergo dissociation. Free ions are produced in quantity, and by means of these the electric charge is transmitted through the gas. Gradually with the coming together of oppositely charged ions the gas will lose its ionised state, and become practically non-conducting as at first.

Ionisation may also be produced by means of incandescent solids. For example, when platinum is heated to a red heat it begins to emit positive ions, for which the ratio e/m has various values. When heated to a higher temperature the platinum will begin to emit negative ions also, and these will become greatly in excess as the temperature is raised to a white heat. Ultimately the negative ions emitted are identical with the negative electrons of the cathode rays.

We are thus led to conceive of a material atom as being built up of negative and positive electrons in a condition of rapid movement. When a negative electron escapes, the remaining part of the atom becomes positively charged. If, as in the case of radium, a positive electron also escapes, the atom is left neutral. The electrical test for the existence of these electrons is much more delicate than any other possible test, whether chemical or optical; and nearly all the knowledge we now possess of the properties of radio-active bodies is the result of refined electrical tests, which were first imagined and applied by Sir J. J. Thomson and his Cambridge school.

It is clear that if the moving electron is to be

the fundamental assumption, magnetism is to be explained as the results of definite motions of electron streams. Ampère, indeed, suggested that a magnetic molecule might be regarded as a small electric circuit. What the modern electron theory does is to give an insight into a possible mechanism for this small electric circuit. Imagine a negative and a positive electron to approach one another under the influence of their mutual attraction with such velocities as will leave them circling round each other somewhat after the manner of the earth and moon. On account of its much smaller mass, the negative electron will describe its orbit with much greater velocities than those of the positive electron; and the magnetic character of the system will be determined by the motion of the negative electron. This system is called a doublet. It will not be deflected by an electric field; and in a magnetic field it will behave like a small magnet whose north pole is on that side from which the negative electron would appear to be moving clockwise.

Moreover, such a doublet will have a certain periodicity, and will start electro-magnetic waves, which, if the frequency is high enough, will become waves of light. The luminous rays from an incandescent vapour may be supposed to be due to vibrating doublets, or even more complex systems of electrons. When a powerful magnetic force is made to act upon such systems, the periodicities will be affected in such a way that instead of only one frequency there may be several of nearly the same value. A single bright line in the spectrum of such a constituted vapour might become doubled or trebled. It can be mathematically shown that under the assigned conditions an effect of this kind is necessary; and we have the experimental demonstration of it in the Zeeman Effect. Zeeman, indeed, was led to look for the phenomenon as a consequence of the electron theory as presented by Lorentz of Leyden.

The existence of magnetic doublets in the cathode discharge has been proved by Righi. Having placed the cathode at one end of a long vacuum tube, and the anode at the end of a short branch tube perpendicular to it, he obtained under suitable conditions of pressure and of magnetic force a glow discharge in the long tube, projected at right angles to the line joining the cathode and anode. This discharge Righi has called the Magnetic Rays. They experience no deflection in an electric field, but are influenced by a magnetic pole brought near. The phenomena are somewhat complicated; but the broad features can be explained in terms of electron doublets produced, probably under the influence of the magnetic field, in the neighbourhood of the cathode. These magnetic rays act as if they consisted of a stream of electrically neutral bodies which were at the same time magnetic molecules. The simplest electrical representation of such a body is the electron doublet.

In recent years an extensive literature bearing on electricity and magnetism has sprung up, and the modern electron theory is making itself felt even in the more elementary works. The standard works in English are the *Experimental Researches of Faraday* (3 vols. 1838–44–55); *Kelvin's Reprint of Papers on Electrostatics and Magnetism* (1872); Clerk Maxwell's *Electricity and Magnetism* (1873; 2d ed. 1881). These, though previous to the introduction of the conception of the electron, had and still have a profound influence in the development of the science. Among the more recent works may be mentioned Sir J. J. Thomson's *Conduction of Electricity through Gases* (1903); J. H. Jeans's *Electricity and Magnetism* (1910); E. T. Whittaker's *History of the Theories of Ether and Electricity* (1910); Rutherford's *Radio-Activity* (1904; new ed. 1912); G. A. Schott's *Electro-Magnetic Radiation* (1912); N. E. Campbell's *Modern Electrical Theory* (2d ed. 1913); Thomson

and Poynting's *Electricity* (1914). W. C. D. Whetham's *Theory of Experimental Electricity* (1905; 2d ed. 1912) gives a clear account of the theory without demanding too high a knowledge of mathematics.

For convenience of reference, we give an epitome of the arrangement of the article. Electrostatics takes up about half of the article, and is followed by Electrokinematics, Electrolysis, Thermo-electricity, Electromagnetism, and Electrons, in that order:

Electrification.
Electroscope, electrometer.
Fundamental experiments.
Potential.
Equipotential surfaces, lines of force.
Capacity; concentric spheres.
Specific inductive capacity.
Instruments for generating electricity.
Loss of energy at discharge.
Transference of charge, current.
Galvanometer.
Electromotive force.
Resistance, Ohm's Law.
Joule's Law.
Electrolysis.
Energy relations of voltaic cells.
Secondary batteries.
Reversible thermal effects of currents.
Thermo-electricity.
Electro-magnetism and magneto-electricity.
Electrons.

Electricity, ANIMAL. See **ELECTRIC FISHES.**

Electricity, ATMOSPHERIC. That the atmosphere, occasionally at least, is in a state of electrification is readily shown by the well-known phenomena of thunder-storms, and that the electrical conditions found on such occasions are the same as that obtained in any laboratory experiment with electrical apparatus was proved by Franklin in 1752 by his famous kite experiment. But since then it has been shown by numerous observations that the atmosphere is constantly in a state of greater or less electrification; that it is sensibly electrified not only during thunder-storms, but also during the prevalence of calm, clear weather. The observations made on the electrical condition of the atmosphere have mainly been the determination of the potential (see **ELECTRICITY**) of the earth's surface at a given time and place, or of the difference between the potential at a point in the air and that at the nearest point on the earth's surface. The distinction between these two determinations may be made clear by an example. If, for instance, a spherical ball be placed on the top of a rod of conducting material in connection with the earth, and having been lifted from that position by an insulated handle or carrier, be taken to an electrometer, with which to measure its potential, we would get by the latter an estimate of the potential of the earth's surface at the place formerly occupied by the rod and ball. If, on the other hand, we imagine a conductor placed at a given point in the air to become insulated, and then to throw from its surface portions of its mass, it would soon be reduced in potential so as to be in electrical equilibrium with the surrounding air—i.e. it will assume the potential of the air at the point. By afterwards finding the potential of this conductor we obtain a determination of the potential of the air at the point, or, what comes to the same thing, of the difference between the potential of the earth and that of the air at the given point.

The first of these methods was employed by Delmann in an extensive series of observations, but it has been by the second that more accurate observations have recently been made. It is, moreover, capable of being so adapted that a continuous record by means of photography may be obtained. Thomson (Lord Kelvin), in his experiments in the island of Arran, employed two forms of this second mode of experiment. In one he used a burning match or spirit flame on the end of a long

vertical insulated conducting rod; the products of combustion continually carry off electricity so long as the potential of the rod is different from that of the air surrounding the flame. The potential of the conductor is thus quickly brought to be the same as the air at the flame. To the lower end of the rod a small portable electrometer is usually attached, from the readings of which the difference between the potential of the earth and that of the air at the flame may be deduced. The other method depends on the same principle. It consists in insulating a can of water which has a long tube projecting from the lower part of its side. The can is usually placed near to and inside the window of a room, while the projecting tube passes through the window. Water is allowed to trickle slowly from the end of the tube at a nozzle, usually a few feet from the window-sill. As each drop falls it carries with it a small charge of electricity, and this goes on until the potential of the can is reduced to that of the air at the nozzle of the tube; this potential is afterwards found by means of the electrometer.

Thus Thomson (Lord Kelvin) found that the difference of potential for a point 9 feet from the ground was equivalent to that of from 200 to 400 Daniell's cells. This represents a resultant force perpendicular to the earth's surface of from about 22 to 44 Daniell's cells per foot. He also found that the electrical conditions were subject to much variation, due no doubt to the motion overhead of electrified cloud-masses, at no great distance from the ground. But generally in calm clear weather the electrometer readings indicated a high positive potential, increasing so markedly before and during east and north-east winds as to be of some value in forecasting the weather. Other observations, chiefly in Europe, show that the potential of the air reaches two maxima and two minima each day, and that the hours of these maxima and minima are different for different seasons of the year. For instance, at Brussels, the two maxima in summer were found to be at 8 A.M. and 9 P.M.; in winter, at 10 A.M. and 6 P.M.

As to the causes of atmospheric electricity, many theories have been propounded, but most of them assume to begin with either some small initial charge of electricity in each vapour particle in a cloud, or some charge of electricity more or less permanent, on the earth's surface. We have only space to mention one or two of the more notable speculations. One which has held a place for some time past is that in which the evaporation going on at the surface of the sea and lakes is made the origin of atmospheric electricity—that in the formation of vapour the particles assume an opposite charge to the mass of liquid which they leave. But it has recently been shown that a much higher temperature is required for such electrification than that which ordinarily is found in large masses of water on the earth's surface. Again, in the condensation of vapour has been sought the source of the phenomena; but that it should be so is difficult to believe, for the very reasons which make the previous speculation somewhat plausible. Some physicists have assumed that the earth has a permanent negative electric charge, and that clouds coming in contact with mountains become charged. That this may be so in special localities is highly probable, yet the original earth's charge is not explained. Thomson (Lord Kelvin) assumed, to begin with, that the lower layers of the atmosphere have a permanent positive charge, which is diffused by convection currents into the upper layers. Atmospheric electricity has also been set down as the result of the friction of dry air against moist air; or, again, by some to the friction of the air in passing over the earth's surface. But this

theory is discredited by the general observation that thunder-storms are more frequent in calm than in windy weather.

The true cause of atmospheric electricity has therefore not yet been discovered. But if any theory can rationally explain a mode by which each small vapour particle in a cloud may become electrified, even with an excessively small charge, the main difficulty would be got over, and the rest would be comparatively easy. The potential of each spherical particle is directly proportional to the quantity of electricity with which it is charged; and when several spheres unite together to form one sphere, the potential of the single sphere is proportional to its surface, compared with the smaller particles of which it is composed. When it is remembered that the number of particles in a drop of water is reckoned at many thousands of billions, it is easy to conceive how a thunder-cloud may have a very high potential, even although the particles may originally have had an extremely small charge.

Meanwhile, it would appear that a widely extended series of observations on the electrical conditions of the atmosphere, together with experiments on a much larger scale than is usual in a laboratory, are necessary requisites before much more light can be thrown on the subject. See LIGHTNING, THUNDER.

Electricity, MEDICAL. The three forms of electricity—Static, Galvanic, and Faradic—are employed in medicine.

(1) *Static*.—This form has been little used of late years, chiefly owing to the inconvenience and uncertainty of the apparatus required for its production. The old frictional and even the Holtz machines were most uncertain in their action, and depended for their efficiency on various conditions of the atmosphere, &c. The recent invention of the Wimshurst machine is increasing the interest in the use of static electricity for medicinal purposes. This instrument being independent of atmospheric conditions is specially well adapted for occasional use.

(2) *Galvanic*.—The current derived from the galvanic battery is largely employed in medicine. As in almost all cases the current requires to traverse the skin, the electrical resistance of which is high, a battery of a considerable number of elements is required to yield sufficient electric pressure. The elements usually employed are some form of the Leclanché or the bichromate element, and batteries containing from 30 to 50 of these are found most convenient. These should yield an electric pressure of from 40 to 70 volts when in good working order. As portability is a consideration, the cells are usually made small, and as the external resistance is considerable and the circuit closed for a comparatively short time, the smallness of the elements is not an objection. When, however, the external resistance is reduced by special appliances, and the current passed for a considerable period, as in the electrolysis of tumours, larger elements must be used, and those of pint or even quart capacity are found convenient. The battery should possess a *collector* by which the cells may be added to the circuit one by one; and the larger-celled batteries should also possess a *rheostat*, by which the external resistance may be varied with perfect gradations so as to avoid the transmission of shocks while the current is being increased or diminished. Until recently the only measure of the amount of electricity employed was the number of cells in the circuit. This is obviously an unreliable guide. The electromotive force of the cells varies with the exhaustion of the fluid and polarisation of the plates, and the resistance of the external circuit varies with the condition of the skin as to moisture,

vascularity, and locality, the size, distance between, and the polarisation of the electrodes. And as the amount of current passing depends on an absolute relation between the electromotive force and the resistance of the current, neither of which under these conditions can be known, this method is quite useless. The unit of current strength in ordinary electric measurement is the *ampère*. This is, however, much too large a unit for medical purposes, and the thousandth part of this, termed the *milliampère*, is employed. Galvanometers calibrated in milliampères are now largely made for medical purposes, so that when one of these is introduced into the circuit the exact amount of current passing at a given time can be read directly. As currents varying from 1 to 300 milliampères are now regularly employed, the instrument should be capable of indicating between those limits. Further, the instrument should be as near as possible aperiodic (dead-beat). Such an instrument should therefore be included in the circuit whenever it is advisable to estimate the current strength employed. Effects can only be compared provided we know the amount of current producing them, and this can only be determined by the milliampère-meter. The efficiency of the current depends, however, not only on its amount, but also on its *density*. This character depends on the diameter of the conductors which bring it in contact with the body. The current-density varies inversely as the sectional area of the conductor. Thus a current of 200 milliampères, conveyed to the body by two conductors whose terminals are 10 inches in diameter, may be borne with little inconvenience and produce little appreciable effect, but if one of the conductors be reduced to, say, 1 inch in diameter while the same current is passing, the density of the current at the electrode is greatly increased, the pain would be intense, and vesication and tissue destruction would follow in a very short time. Currents of large amount and of great density are thus employed in the electrolysis of tumours, &c.

Well-insulated flexible wires of suitable length are employed for conveying the current. These terminate in electrodes of various kinds and sizes according to the object in view. For ordinary purposes (galvanisation of muscle, nerve, &c.) discs, plates, or cones of brass or carbon covered with flannel or wash-leather are employed. For conveyance of large currents large pads of moist clay, flannel, sponge, &c., 10 or 12 or more inches in diameter, are employed externally, while the current is concentrated by a platinum or steel needle on the part to be affected. In all cases electrodes to be applied to the skin should be thoroughly soaked in a solution of salt in warm water in order to diminish the resistance of the circuit and the pain of the current.

(3) *Faradic*.—For the production of the faradic current a simple form of induction coil is employed. The primary coil of thick wire is wound round a tube in which slides a bundle of iron wire. The secondary coil of fine wire fits over this. In the best forms of instrument the strength of the current can be regulated both by the sliding of the iron bundle in and out of the primary, and also by the sliding of the secondary over, or off and away from the primary. The induced or faradic current is generated in the secondary coil only when the primary current begins to flow and ceases to flow. See ELECTRICITY. It is convenient to have attached to the induction an automatic electromagnetic make-and-break, usually called the interrupter. The result is that the primary circuit is no sooner made than it is broken, and no sooner broken than it is made again. This goes on in rapid alternation, and is accompanied by the pro-

duction of induced currents, first in one direction, then in the other. Since the breaking of the primary is a more abrupt process than the making of it, the induced current at break goes through its successive values with corresponding rapidity, and has a more intense physiological effect than the induced current at make.

Physiological Effects of the Galvanic Current: (a) *On Sensory Surfaces.*—When a current of from 10 to 15 milliamperes is applied to the skin by electrodes of 1 or 2 inches in diameter, a prickling followed by a burning sensation is experienced. If the current is gradually diminished and the electrodes removed, the skin will be found to be bright red, showing increased vascularity. While the current is being diminished it will be noticed that the sensation first disappears under the positive pole, and while being increased first appears at the negative one, thus indicating the greater exciting effect of the latter. (b) *On Motor Apparatus.*—If a large sponge electrode be applied to the spine in the dorsal region, and a smaller conical one be applied to such a muscle as the biceps in the upper arm, it will be found that if a current of sufficient strength be employed, the muscle will be thrown into contraction at the moment of making and breaking the current. The strength of current required to produce this effect will depend (1) on the pole applied to the muscle; (2) on whether the current is made or broken. In a state of health it is found that muscular contraction occurs with those conditions in the following order: (1) current closed—negative on muscle; (2) current closed—positive on muscle; (3) current opened—positive on muscle; (4) current opened—negative on muscle. Thus the weakest current capable of producing contraction will act when the current is closed with the negative on the muscle (1); and stronger currents will be required to produce contraction under the conditions 2, 3, 4. Or conversely, if a muscle contracts with an opening current, the negative being on the muscle (4), more and more powerful contractions will be obtained by altering the conditions with the same current to 3, 2, and 1.

Electrolytic Effects.—If a broad surface-electrode be applied to any part of the body and connected to one pole, and the other pole connected to a platinum or steel needle inserted into, say, a fibroid tumour of the uterus, or applied to any mucous surface, and a current of 15 to 250 milliamperes passed, tissue in contact with the electrodes will be decomposed. Owing to the extent of the external electrode and small density of the current, the result here will be inappreciable, but it is very obvious at the internal one. Thus, if the electrode is positive, the products of decomposition will be strongly acid in reaction (turning litmus red), and the tissue round the electrode will be condensed, and contract round it. If the internal electrode is now negative, the products of decomposition will be strongly alkaline in reaction, and the tissue will be rapidly broken up, a loose frothy material escaping from the electrode, which will move freely in a sinus formed by the electrolysis. The negative pole while liberating alkaline products has much more marked disintegrating influence than the positive.

Physiological Effect of Induced Currents: (a) *On Sensory Apparatus.*—When a weak current from the secondary is applied to the skin, the sensation is that of gentle prickling or tingling. As the strength of the current is increased the sensation becomes more and more painful, but has never the burning character of the galvanic current. (b) *On Motor Apparatus.*—If one or both poles are applied to a muscle, and a single shock of sufficient strength sent, a single muscular contraction will be produced. If the shocks are repeated with

sufficient slowness, a series of single contractions will follow; but if the rate of transmission is increased, the muscle will be thrown into a state of tetanus or continued contraction, the effect of one shock not having passed before the next has reached the muscle.

Diagnostic Uses of Electricity.—Galvanic and faradic currents are employed in the diagnosis of various nervous and muscular disorders. In certain diseases of the spinal cord and the cerebro-spinal nerves it is found that the normal phenomena of muscular contraction are much altered. Thus it may be found that a muscle may fail to respond to faradic stimuli of any strength, and yet continue to respond to interrupted galvanic stimuli; and again it may respond to galvanic stimuli in an order different to that indicated in a previous paragraph as normal to health. These abnormal phenomena are termed the 'reactions of degeneration.'

Therapeutic Uses of Electricity.—Only the most general indications of these can be given. The static form is of value in the treatment of various nervous disorders—e.g. old-standing neuralgia, chorea, hemi-anæsthesia, hystero-epilepsy, and hysteria. *Galvanism* is used in acute neuralgias, such as tic-douloureux, sciatica, &c.; in atrophy of muscle following hemiplegia, diabetes, writers' cramp, &c.; in spinal irritation, chronic myelitis; in the enlarged and stiffened joints of chronic rheumatism and rheumatic arthritis, and in lumbago; in chronic pharyngitis, in glandular laryngitis (clergyman's sore throat), naso-pharyngeal catarrh, chronic tonsillitis; and in other diseases associated with chronic inflammation and defective nutrition. *Faradism* is employed in general nervous exhaustion associated with insomnia, in functional disorders of the generative organs, in the acute stage of articular rheumatism, giving great relief to the inflamed and painful joints, in incontinence of urine from atony of bladder and sphincter, in irritable and painful prostate, in hysterical aphonia, neurasthenia, &c.

Galvanism in Electrolysis.—Nævi and aneurisms are frequently cured by electrolysis of their contents. Needles insulated to within a quarter of an inch of their points are plunged into the tumour, and through these the current is passed. Coagulation takes place round the needles, and forms a nucleus round which further clotting occurs, resulting in obliteration of the nævus, or strengthening of the walls and filling of the sac in an aneurism. For uterine hemorrhage a current of 100 to 250 milliamperes is employed, a thick platinum wire carrying the *positive* current to the mucous membrane of the uterus, a large surface-electrode lying on the abdomen. The positive current is a powerful hæmostatic, and properly applied this method checks most cases of hemorrhage. So also fibroid tumours of the uterus are treated by similar high currents applied in the same way. But the disintegrating effect of the negative pole is preferred either lying in the uterine cavity or introduced into the substance of the tumour. Various inflammatory conditions both outside and inside the uterus are similarly treated. All these effects depend (1) on the strength of the current, which is obtained by the use of a sufficiently large pressure (30 to 40 cells = 40 or 60 volts), and a large surface external electrode which diminishes the resistance of the skin; (2) on the density of the current at the part to be affected, which is obtained by the use of an electrode consisting of a small platinum or steel needle.

In conclusion, a word may be said regarding the much advertised 'galvanic' and 'magnetic' belts. There is no doubt that galvanic chains, such as Pulvermacher's, are capable of giving a more or

less continuous current of electricity, and it may be that in some cases their use has been followed by benefit. But the irregularity of their action, and the impossibility of directing or controlling the current, render their use entirely hap-hazard. Moreover, very troublesome ulcerations have been produced in the skin by prolonged contact of the negative pole. On the other hand, there is not the least evidence that the so-called 'magnetic belts' have any influence whatever on the tissues or functions of the body. They consist of pieces of watch-spring, or of crinoline steel, more or less magnetised, sewn between layers of flannel or other material, and adapted to different parts of the body. It has never been shown that even powerful magnets have any influence on the bodily functions, and it cannot be believed that these appliances are of any use whatever. Any relief from pain which may follow their application is most probably due to the heat-conserving property of the flannel or other material in which the bits of steel are sewn.

Electric Light. The electric light, like light from most other sources, is produced by raising a body to a temperature so high that some of the radiations it throws out have a wave-length short enough to affect the retina. A slightly heated body gives radiations of long wave-length only; they may be detected, as any radiations may, by their heating effect when they fall on an absorbent surface, but the eye is not sensitive to them. When the body is made hotter the whole energy of the radiations increases, but the short waves increase in greater proportion than the long waves, and when the temperature is sufficiently raised the body begins to give out light. So long as the source is just hot enough to be luminous the light is nearly all red; as the temperature rises there are added more and more of the other colours, of shorter wave-length, towards the violet end of the spectrum. In the flame of a candle or of a gas-jet particles of solid carbon form the luminous source: their temperature, which is determined by the condition that they radiate energy as fast as work is done upon them by the process of combustion, is so low as to make the red and yellow constituents of the light preponderate. A higher temperature has the double advantage of giving whiter light, and of giving it accompanied by a smaller proportion of non-luminous infra-red rays, and therefore with less expenditure of energy in proportion to the amount of light produced.

One way of heating a body to a high temperature is by forcing a strong current of electricity to pass through it. The energy expended depends on the strength of the current and on the electromotive force which is required to make it pass, and this energy takes the form of heat. By selecting a conductor which offers considerable resistance to the passage of the current, it is practicable to produce so much heat in a small space that the temperature reached is only limited by the melting or volatilising of the heated body.
